Introduction to the First Edition

The *CRC Concise Encyclopedia of Mathematics* is a compendium of mathematical definitions, formulas, figures, tabulations, and references. It is written in an informal style intended to make it accessible to a broad spectrum of readers with a wide range of mathematical backgrounds and interests. Although mathematics is a fascinating subject, it all too frequently is clothed in specialized jargon and dry formal exposition that make many interesting and useful mathematical results inaccessible to laypeople. This problem is often further compounded by the difficulty in locating concrete and easily understood examples. To give perspective to a subject, I find it helpful to learn why it is useful, how it is connected to other areas of mathematics and science, and how it is actually implemented. While a picture may be worth a thousand words, explicit examples are worth at least a few hundred! This work attempts to provide enough details to give the reader a flavor for a subject without getting lost in minutiae. While absolute rigor may suffer somewhat, I hope the improvement in usefulness and readability will more than make up for the deficiencies of this approach.

The format of this work is somewhere between a handbook, a dictionary, and an encyclopedia. It differs from existing dictionaries of mathematics in a number of important ways. The entries are extensively cross-referenced, not only to related entries but also to many external sites on the Internet. This makes locating information very convenient. It also provides a highly efficient way to "navigate" from one related concept to another. Standard mathematical references, combined with a few popular ones, are also given at the end of most entries to facilitate additional reading and exploration. In the interests of offering abundant examples, this work also contains a large number of explicit, formulas and derivations, providing a ready place to locate a particular formula, as well as including the framework for understanding where it comes from.

The selection of topics in this work is more extensive than in most mathematical dictionaries (e.g., Borowski and Borwein's *HarperCollins Dictionary of Mathematics* and Jeans and Jeans' *Mathematics Dictionary*). At the same time, the descriptions are more accessible than in "technical" mathematical encyclopedias (e.g., Hazewinkel's *Encyclopaedia of Mathematics* and Iyanaga's *Encyclopedic Dictionary of Mathematics*). While the latter remain models of accuracy and rigor, they are not terribly useful to the undergraduate, research scientist, or recreational mathematician. In this work, the most useful, interesting, and entertaining (at least to my mind) aspects of topics are discussed in addition to their technical definitions. For example, in my entry for pi (π), the definition in terms of the diameter and circumference of a circle is supplemented by a great many formulas and series for pi, including some of the amazing discoveries of Ramanujan. These formulas are comprehensible to readers with only minimal mathematical background, and are interesting to both those with and without formal mathematics training. However, they have not previously been collected in a single convenient location. For this reason, I hope that, in addition to serving as a reference source, this work has some of the same flavor and appeal of Martin Gardner's delightful *Scientific American* columns.

Everything in this work has been compiled by me alone. I am an astronomer by training, but have picked up a fair bit of mathematics along the way. It never ceases to amaze me how mathematical connections weave their way through the physical sciences. It frequently transpires that some piece of recently acquired knowledge turns out to be just what I need to solve some apparently unrelated problem. I have therefore developed the habit of picking up and storing away odd bits of information for future use. This work has provided a mechanism for organizing what has turned out to be a fairly large collection of mathematics. I have also found it very difficult to find clear yet accessible explanations of technical mathematics unless I already have some familiarity with the subject. I hope this encyclopedia will provide jumping-off points for people who are interested in the subjects listed here but who, like me, are not necessarily experts.

The encyclopedia has been compiled over the last 11 years or so, beginning in my college years and continuing during graduate school: The initial document was written in *Microsoft Word*® on a Mac Plus® computer, and had reached about 200 pages by the time I started graduate school in 1990. When Andrew Treverrow made his OzTEX program available for the Mac; I began the task of converting all my documents to TEX resulting in a vast improvement in readability. While undertaking the *Word* to TEX conversion, I also began cross-referencing entries, anticipating that eventually I would be able to convert the entire document to hypertext. This hope was realized beginning in 1995, when the Internet explosion was in full swing and I learned of Nikos Drakos's excellent TEX to HTML converter, LATEX2HTML. After some additional effort, I was able to post an HTML version of my encyclopedia to the World Wide Web.

The selection of topics included in this compendium is not based on any fixed set of criteria, but rather reflects my own random walk through mathematics. In truth, there is no good way of selecting topics in such a work. The mathematician James Sylvester may have summed up the situation most aptly. According to

Sylvester (as quoted in the introduction to Ian Stewart's book *From Here to Infinity*), "Mathematics is not a book confined within a cover and bound between brazen clasps, whose contents it needs only patience to ransack; it is not a mine, whose treasures may take long to reduce into possession, but which fill only a limited number of veins and lodes; it is not a soil, whose fertility can be exhausted by the yield of successive harvests; it is not a continent or an ocean, whose area can be mapped out and its contour defined; it is as limitless as that space which it finds too narrow for its aspiration; its possibilities are as infinite as the worlds which are forever crowding in and multiplying upon the astronomer's gaze; it is as incapable of being restricted within assigned boundaries or being reduced to definitions of permanent validity, as the consciousness of life."

Several of Sylvester's points apply particularly to this undertaking: As he points out, mathematics itself cannot be confined to the pages of a book. The results of mathematics, however, are shared and passed on primarily through the printed (and now electronic) medium. While there is no danger of mathematical results being lost through lack of dissemination, many people miss out on fascinating and useful mathematical results simply because they are not aware of them. Not only does collecting many results in one place provide a single starting point for mathematical exploration, but it should also lessen the aggravation of encountering explanations for new concepts which themselves use unfamiliar terminology. In this work, the reader is only a cross-reference away from the necessary background material. As to Sylvester's second point, the very fact that the quantity of mathematics is so great means that any attempt to catalog it with any degree of completeness is doomed to failure. This certainly does not mean that it's not worth trying. Strangely, except for relatively small works usually on particular subjects, there do not appear to have been any substantial attempts to collect and display in a place of prominence the treasure trove of mathematical results that have been discovered (invented?) over the years (one notable exception being Sloane and Plouffe's *Encyclopedia of Integer Sequences*). This work, the product of the "gazing" of a single astronomer, attempts to fill that omission.

Finally, a few words about logistics. Because of the alphabetical listing of entries in the encyclopedia, neither table of contents nor index are included. In many cases, a particular entry of interest can be located from a cross-reference (indicated in SMALL CAPS TYPEFACE in the text) in a related article. In addition, most articles are followed by a "see also" list of related entries for quick navigation. This can be particularly useful if you are looking for a specific entry (say, "Zeno's Paradoxes"), but have forgotten the exact name. By examining the "see also" list at bottom of the entry for "Paradox," you will likely recognize Zeno's name and thus quickly locate the desired entry.

In cases where the same word is applied in different contexts, the context is indicated in parentheses or appended to the end. Examples of the first type are "Crossing Number (Graph)" and "Crossing Number (Link)." Examples of the second type are "Convergent Sequence" and "Convergent Series." In the case of an entry like "Euler Theorem," which may describe one of three or four different formulas, I have taken the liberty of adding descriptive words ("Euler's Something Theorem") to all variations, or kept the standard name for the most commonly used variant and added descriptive words for the others. In cases where specific examples are derived from a general concept, em dashes (—) are used (for example, "Fourier Series," "Fourier Series — Power Series," "Fourier Series — Square Wave," "Fourier Series — Triangle"). The decision to put a possessive 's at the end of a name or to use a lone trailing apostrophe is based on whether the final "s" is pronounced. "Gauss's Theorem" is therefore written out, whereas "Archimedes' Recurrence Formula" is not. Finally, given the absence of a definitive stylistic convention, plurals of numerals are written without an apostrophe (e.g., 1990s instead of 1990's).

In an endeavor of this magnitude, errors and typographical mistakes are inevitable. The blame for these lies with me alone. Although the current length makes extensive additions in a printed version problematic, I plan to continue updating, correcting, and improving the work..

Eric Weisstein
Charlottesville, Virginia
August 8, 1998

Preface to the New Edition

The long awaited second edition of this Encyclopedia is finished, and it is now more complete than ever. Heavily revised by the author Eric Weisstein over the past three years, it contains well over 3,000 pages. Mr. Weisstein has updated all of the original material, added approximately 3,600 new entries and many illustrations, and updated the bibliographies that follow each entry to include the most recent references. As yet another enhancement, this edition integrates the use of the Mathematica software into many of its entries, presenting the precise commands that allow you to implement the formulas presented, perform many different calculations, construct graphical displays of your results, and generate remarkable mathematical illustrations. This is a unique touch and to our knowledge, a first for an encyclopedia.

With definitions, formulas, and facts presented in clear, engaging prose along with a multitude of illustrations, extensive cross-references, and even links to the Internet, this new and improved edition remains one of the most readable and accessible references in mathematics. This is truly a unique book written by an individual who is clearly dedicated to the study and field of mathematics. Users of the first edition of the Encyclopedia have described it as “extraordinary,” “impressive,” and “fascinating, “ and report spending hours browsing its pages simply for pleasure. We hope you will do the same.

Acknowledgments

Although I alone have compiled and typeset this work, many people have contributed indirectly and directly to its creation. I have not yet had the good fortune to meet Donald Knuth of Stanford University, but he is unquestionably the person most directly responsible for making this work possible. Before his mathematical typesetting program TEX, it would have been impossible for a single individual to compile such a work as this. Had Prof. Bateman owned a personal computer equipped with TEX, perhaps his shoe box of notes would not have had to await the labors of Erdelyi, Magnus, and Oberhettinger to become a three-volume work on mathematical functions. Andrew Trevorrow's shareware implementation of TEX for the Macintosh, OzTEX (www.kagi.com/authors/akt/oztex.html), was also of fundamental importance. Nikos Drakos and Ross Moore have provided another building block for this work by developing the LATEX2HTML program (www-dsed.llnl.gov/files/programs/unix/latex2html/manual/manual.html), which has allowed me to easily maintain and update an on-line version of the encyclopedia long before it existed in book form.

I would like to thank Steven Finch of MathSoft, Inc., for his interesting on-line essays about mathematical constants (www.mathsoft.com/asolve/constant/constant.html), and also for his kind permission to reproduce excerpts from some of these essays. I hope that Steven will someday publish his detailed essays in book form. Thanks also to Neil Sloane and Simon Plouffe for compiling and making available the printed and on-line (www.research.att.com/~njas/sequences/) versions of the Encyclopedia of Integer Sequences, an immensely valuable compilation of useful information which represents a truly mind-boggling investment of labor.

Thanks to Robert Dickau, Simon Plouffe, and Richard Schroeppel for reading portions of the manuscript and providing a number of helpful suggestions and additions. Thanks also to algebraic topologist Ryan Budney for sharing some of his expertise, to Charles Walkden for his helpful comments about dynamical systems theory, and to Lambros Lambrou for his contributions. Thanks to David W. Wilson for a number of helpful comments and corrections. Thanks to Dale Rolfsen, compiler James Bailey, and artist Ali Roth for permission to reproduce their beautiful knot and link diagrams. Thanks to Gavin Theobald for providing diagrams of his masterful polygonal dissections. Thanks to Wolfram Research, not only for creating an indispensable mathematical tool in *Mathematica*®, but also for permission to include figures from the *Mathematica*® book and *MathSource* repository for the braid, conical spiral, double helix, Enneper's surfaces, Hadamard matrix, helicoid, helix, Henneberg's minimal surface, hyperbolic polyhedra, Klein bottle, Maeder's "owl" minimal surface, Penrose tiles, polyhedron, and Scherk's minimal surfaces entries.

Sincere thanks to Judy Schroeder for her skill and diligence in the monumental task of proofreading the entire document for syntax. Thanks also to Bob Stern, my executive editor from CRC Press, for his encouragement, and to Mimi Williams of CRC Press for her careful reading of the manuscript for typographical and formatting errors. As this encyclopedia's entry on PROOFREADING MISTAKES shows, the number of mistakes that are expected to remain after three independent proofreadings is much lower than the original number, but unfortunately still nonzero. Many thanks to the library staff at the University of Virginia, who have provided invaluable assistance in tracking down many an obscure citation. Finally, I would like to thank the hundreds of people who took the time to e-mail me comments and suggestions while this work was in its formative stages. Your continued comments and feedback are very welcome.

Numerals

(−1, 0, 1)-Matrix

The number of distinct $(-1, 0, 1)$-$n \times n$ matrices (counting row and column permutations, the transpose, and multiplication by -1 as equivalent) having $2n$ different row and column sums for $n = 2, 4, 6, ...$ are 1, 4, 39, 2260, 1338614, ... (Kleber). For example, the 2×2 matrix is given by

$$\begin{bmatrix} -1 & -1 \\ 0 & 1 \end{bmatrix},$$

To get the total number from these counts (assuming that 0 is not the missing sum, which is true for $n \leq 10$), multiply by $(2n!)^2$. In general, if an -matrix which has different column and row sums (collectively called line sums), then

1. n is even,
2. The number in $\{-n, 1-n, 2-n, \ldots, n\}$ that does not appear as a line sum is either $-n$ or , and
3. Of the largest line sums, half are column sums and half are row sums

(Bodendiek and Burosch 1995, F. Galvin).

0 = 1

Fallacy

(0, 1)-Matrix

A (0, 1)-integer matrix, i.e., a matrix each of whose elements is 0 or 1, also called a binary matrix.

The numbers of binary matrices with no adjacent 1s (in either columns or rows) for $n = 1, 2, ...$, are given by 2, 7, 63, 1234, ... (Sloane's A006506). For example, the binary matrices with no adjacent 1s are

$$\begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix}, \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}$$

$$\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}, \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix},$$

These numbers are closely related to the hard square entropy constant. The numbers of binary matrices with no *three* adjacent 1s for , 2, ..., are given by 2, 16, 265, 16561, ... (Sloane's A050974).

Wilf (1997) considers the complexity of transforming an $m \times n$ binary matrix A into a triangular matrix by permutations of the rows and columns of , and concludes that the problem falls in difficulty between a known easy case and a known hard case of the general NP-complete problem.

1

The number one (1), also called "unity" is the first positive integer. It is an odd number. Although the number 1 used to be considered a prime number, it

requires special treatment in so many definitions and applications involving primes greater than or equal to 2 that it is usually placed into a class of its own (Wells 1986, p. 31). The number 1 is sometimes also called "unity," so the th roots of 1 are often called the th ROOTS OF UNITY. FRACTIONS having 1 as a NUMERATOR are called UNIT FRACTIONS. If only one root, solution, etc., exists to a given problem, the solution is called UNIQUE.

The GENERATING FUNCTION having all COEFFICIENTS 1 is given by

$$\frac{1}{1-x} = 1 + x + x^2 + x^3 + x^4 + \ldots.$$

See also FALLACY, ONE-FORM, ONE-MOUTH THEOREM, ONE-NINTH CONSTANT, ONE-SHEETED HYPERBOLOID, ONE-TO-ONE, ONE-WAY FUNCTION, 2, 3, COMPLEXITY (NUMBER), EXACTLY ONE, ROOT OF UNITY, UNIQUE, UNIT FRACTION, ZERO

References

Wells, D. *The Penguin Dictionary of Curious and Interesting Numbers.* Middlesex, England: Penguin Books, pp. 30–32, 1986.

2

The number two (2) is the second POSITIVE INTEGER and the first PRIME NUMBER. It is EVEN, and is the only EVEN PRIME (the PRIMES other than 2 are called the ODD PRIMES). The number 2 is also equal to its FACTORIAL since $2! = 2$. A quantity taken to the POWER 2 is said to be SQUARED. The number of times k a given BINARY number $b_n \cdots b_2 b_1 b_0$ is divisible by 2 is given by the position of the first $b_k = 1$, counting from the right. For example, $12 = 1100$ is divisible by 2 twice, and $13 = 1101$ is divisible by 2 zero times.

The only known solutions to the CONGRUENCE

$$2^n \equiv 3 \pmod{n}$$

are $n = 4700063497$ (Sloane's A050259; Guy 1994) and

63130707451134435989380140059866138830623361447484274774099906755

(P.-L. Montgomery 1999). In general, the least satisfying

$$2^n \equiv k \pmod{n}$$

for $k = 2, 3, \ldots$ are $n = 3$, 4700063497, 6, 19147, 10669, 25, 9, 2228071, ... (Sloane's A036236).

2x mod 1 Map

Let x_0 be a RATIONAL NUMBER in the CLOSED INTERVAL $[0, 1]$, and generate a SEQUENCE using the MAP

$$x_{n+1} \equiv 2x_n \pmod{1}. \quad (1)$$

Then the number of periodic ORBITS of period p (for PRIME) is given by

$$N_p = \frac{2^p - 2}{p} \quad (2)$$

(i.e, the number of period- repeating bit strings, modulo shifts). Since a typical ORBIT visits each point with equal probability, the NATURAL INVARIANT is given by

$$\rho(x) = 1. \quad (3)$$

See also TENT MAP

3

3 is the only INTEGER which is the sum of the preceding POSITIVE INTEGERS ($1 + 2 = 3$) and the only number which is the sum of the FACTORIALS of the preceding POSITIVE INTEGERS ($1! + 2! = 3$). It is also the first ODD PRIME. A quantity taken to the POWER 3 is said to be CUBED.

The sequence 1, 31, 331, 3331, 33331, ... (Sloane's A033175) consisting of $n = 0, 1, \ldots$ 3s followed by a 1. The th tern is given by

$$a(n) = \frac{10^{n+1} - 7}{3}.$$

The result is prime for , 2, 3, 4, 5, 6, 7, 17, 39, ... (Sloane's A055520); i.e., for 3, 31, 331, 3331, 33331, 333331, 3333331, 33333331, ... (Sloane's A051200), a fact which Gardner (1997) calls "a remarkable pattern that is entirely accidental and leads nowhere."

4-D Geometry

4-Dimensional Geometry

4-Dimensional Geometry

4-dimensional geometry is Euclidean geometry extended into one additional dimension. The prefix "hyper-" is usually used to refer to the 4- (and higher-) dimensional analogs of 3-dimensional objects, e.g. Hypercube, hyperplane, hypersphere. -dimensional polyhedra are called polytopes. the 4-dimensional cases of general -dimensional objects are often given special names, such as those summarized in the following table.

2-D	3-D	4-D	General
circle	sphere	glome	hypersphere
square	cube	tesseract	hypercube
equilateral triangle	tetrahedron	pentatope	simplex
polygon	polyhedron	polychoron	polytope
line segment	plane	hyperplane	hyperplane
square	octahedron	16-cell	cross polytope
edge	face	facet	facet
area	volume	content	content

The surface area of a hypersphere in -D is given by

$$S_n = \frac{2\pi^{n/2}}{\Gamma\left(\frac{1}{2}n\right)},$$

and the volume by

$$V_n = \frac{\pi^{n/2}R^n}{\Gamma\left(1+\frac{1}{2}n\right)},$$

where $\Gamma(n)$ is the gamma function.

6-Sphere Coordinates

The coordinate system obtained by INVERSION of CARTESIAN COORDINATES, with $u, v, w \in (-\infty, \infty)$. The transformation equations are

$$x = \frac{u}{u^2 + v^2 + w^2} \tag{1}$$

$$y \frac{v}{u^2 + v^2 + w^2} \tag{2}$$

$$z \frac{w}{u^2 + v^2 + w^2}. \tag{3}$$

The equations of the surfaces of constant coordinates are given by

$$\left(x - \frac{1}{2u}\right)^2 + y^2 + z^2 = \frac{1}{4u^2}, \tag{4}$$

which gives spheres tangent to the yz-plane at the origin for u constant,

$$x^2 + \left(y - \frac{1}{2v}\right)^2 + z^2 = \frac{1}{4v^2}, \tag{5}$$

which gives spheres tangent to xz-plane at the origin for v constant, and

$$x^2 + y^2 + \left(z - \frac{1}{2w}\right)^2 = \frac{1}{4w^2}. \tag{6}$$

which gives spheres tangent to the xy-plane at the origin for w constant.
The metric coefficients are

$$g_{uu} = g_{vv} = g_{ww} = \frac{1}{(u^2 + v^2 + w^2)^2}. \tag{7}$$

10

The number 10 (ten) is the basis for the DECIMAL system of notation. In this system, each "decimal place" consists of a DIGIT 0–9 arranged such that each DIGIT is multiplied by a POWER of 10, decreasing from left to right, and with a decimal place indicating the $10^0 = 1$s place. For example, the number 1234.56 specifies

$$1 \times 10^3 + 2 \times 10^2 + 3 \times 10^1 + 4 \times 10^0 + 5 \times 10^{-1} + 6 \times 10^{-2}.$$

The decimal places to the left of the decimal point are 1, 10, 100, 1000, 10000, 100000, 1000000, 10000000, 100000000, ... (Sloane's A011557), called one, ten, HUNDRED, THOUSAND, ten thousand, hundred thousand, MILLION, 10 million, 100 million, and so on. The names of subsequent decimal places for LARGE NUMBERS differ depending on country.

Any POWER of 10 which can be written as the PRODUCT of two numbers not containing 0s must be OF THE FORM $2^n \cdot 5^n = 10^n$ for an INTEGER such that neither 2^n nor 5^n contains any ZEROS. The largest known such number is

$$10^{23} = 2^{33} \cdot 5^{33} = 8,\ 589,\ 934,\ 592 \cdot 116,\ 415,\ 321,\ 826,\ 934,\ 814,\ 453,\ 125.$$

A complete list of known such numbers is

$$\begin{aligned} 10^1 &= 2^1 \cdot 5^1 \\ 10^2 &= 2^2 \cdot 5^2 \\ 10^3 &= 2^3 \cdot 5^3 \\ 10^4 &= 2^4 \cdot 5^4 \\ 10^5 &= 2^5 \cdot 5^5 \\ 10^6 &= 2^6 \cdot 5^6 \\ 10^7 &= 2^7 \cdot 5^7 \\ 10^9 &= 2^9 \cdot 5^9 \\ 10^{18} &= 2^{18} \cdot 5^{18} \\ 10^{33} &= 2^{33} \cdot 5^{33} \end{aligned}$$

(Madachy 1979). Since all POWERS of 2 with exponents $86 < n \le 4.6 \times 10^7$ contain at least one ZERO (M. Cook), no other POWER of ten less than 46 million can be written as the PRODUCT of two numbers not containing 0s.

See also 15 PUZZLE, FIFTEEN THEOREM

15 Puzzle

1	2	3	4
5	6	7	8
9	10	11	12
13	14	15	

A puzzle introduced by Sam Loyd in 1878. It consists of 15 squares numbered from 1 to 15 which are placed in a 4×4 box leaving one position out of the 16 empty. The goal is to reposition the squares from a given arbitrary starting arrangement by sliding them one at a time into the configuration shown above. For some initial arrangements, this rearrangement is possible, but for others, it is not.

To address the solubility of a given initial arrangement, proceed as follows. If the SQUARE containing the number i appears "before" (reading the squares in the box from left to right and top to bottom) numbers which are less than , then call it an inversion of order , and denote it n_i. Then define

$$N \equiv \sum_{i=1}^{15} n_i = \sum_{i=2}^{15} n_i,$$

where the sum need run only from 2 to 15 rather than 1 to 15 since there are no numbers less than 1 (so n_1 must equal 0). If N is EVEN, the position is possible, otherwise it is not. This can be formally proved using ALTERNATING GROUPS. For example, in the following arrangement

2	1	3	4
5	6	7	8
9	10	11	12
13	14	15	

$n_2 = 1$ (2 precedes 1) and all other $n_i = 0$, so $N = 1$ and the puzzle cannot be solved.

Johnson (1879) proved that odd permutations of the puzzle are impossible, which Story (1879) proved that all even permutations are possible. While Herstein and Kaplansky (1978) wrote that "no really easy proof seems to be known," Archer (1999) presented a simple proof. A more general result due to Wilson (1974) showed that for any CONNECTED GRAPH on nodes, with the exception of CYCLE GRAPHS C_n and the THETA-0 GRAPH, either exactly half or all of the $n!$ possible labelings are obtainable by sliding labels, depending on whether the graph is BIPARTITE (Archer 1999). θ_0 has six inequivalent labelings, which has $(n-2)!$ inequivalent labelings.

Reversing the order of the "8 Puzzle" made on a 3×3 board can be proved to require at least 26 moves, although the best solution requires 30 moves (Gardner 1984, pp. 200 and 206–207). The number of distinct solutions in 28, 30, 32, ... moves are 0, 10, 112, 512, ... (Sloane's A046164), giving 634 solutions better than the 36-move solution given by Dudeney (1949).

17-gon

HEPTADECAGON

18-Point Problem

Place a point somewhere on a LINE SEGMENT. Now place a second point and number it 2 so that each of the points is in a different half of the LINE SEGMENT. Continue, placing every th point so that all points are on different $(1/N)$th of the LINE SEGMENT. Formally, for a given , does there exist a sequence of real numbers x_1, x_2, ..., x_N such that for every $n \in \{1, \ldots, N\}$ and every $k \in \{1, \ldots, n\}$, the inequality

$$\frac{k-1}{n} \leq x_i < \frac{k}{n}$$

holds for some $i \in \{1, \ldots, n\}$? Surprisingly, it is only possible to place 17 points in this manner (Berlekamp and Graham 1970, Warmus 1976).

Steinhaus (1979) gives a 14-point solution (0.06, 0.55, 0.77, 0.39, 0.96, 0.28, 0.64, 0.13, 0.88, 0.48, 0.19, 0.71, 0.35, 0.82), and Warmus (1976) gives the 17-point solution

$$\tfrac{4}{7} \leq x_1 < \tfrac{7}{12},\ \tfrac{2}{7} \leq x_2 < \tfrac{5}{17},\ \tfrac{16}{17} \leq x_3 < 1,\ \tfrac{1}{14} \leq x_4 < \tfrac{1}{13},$$

$$\tfrac{8}{11} \leq x_5 < \tfrac{11}{15},\ \tfrac{5}{11} \leq x_6 < \tfrac{6}{13},\ \tfrac{1}{7} \leq x_7 < \tfrac{2}{13},\ \tfrac{14}{17} \leq x_8 < \tfrac{5}{6},$$

$$\tfrac{3}{8} \leq x_9 < \tfrac{5}{13},\ \tfrac{11}{17} \leq x_{10} < \tfrac{2}{3},\ \tfrac{3}{14} \leq x_{11} < \tfrac{3}{13},$$

$$\tfrac{15}{17} \leq x_{12} < \tfrac{11}{12},\ \tfrac{1}{2} \leq x_{12} < \tfrac{9}{17},\ 0 \leq x_{14} < \tfrac{1}{17},$$

$$\tfrac{13}{17} \leq x_{15} < \tfrac{4}{5},\ \tfrac{5}{16} \leq x_{16} < \tfrac{6}{17},\ \tfrac{10}{17} \leq x_{17} < \tfrac{11}{17},$$

Warmus (1976) states that there are 768 patterns of 17-point solutions (counting reversals as equivalent).

24-Cell

A finite regular 4-D POLYTOPE with SCHLÄFLI SYMBOL {3, 4, 3}. Coxeter (1969) gives a list of the VERTEX positions. The EVEN coefficients of the D_4 lattice are 1, 24, 24, 96, ... (Sloane's A004011), and the 24 shortest vectors in this lattice form the 24-cell (Coxeter 1973, Conway and Sloane 1993, Sloane and Plouffe 1995). The 24-cell is self-dual, and is the unique regular convex POLYCHORON which has no direct 3-D analog.

One construction for the 24-cell evokes comparison with the RHOMBIC DODECAHEDRON. Given two equal cubes, we construct this dodecahedron by cutting one cube into six congruent square pyramids, and attaching these to the six squares bounding the other cube. Similarly, given two equal tesseracts, we can construct the 24-cell by cutting one tesseract into eight congruent cubic pyramids, and attaching these to the eight cubes bounding the other tesseract (Towle).

144

A dozen dozen, also called a gross. 144 is a square number and a sum-product number.

See also Dozen

163

The number 163 is very important in number theory, since $d = 163$ is the largest number such that the imaginary quadratic field $\mathbb{Q}\left(-\sqrt{d}\right)$ has class number $h(-d) = 1$. It also satisfies the curious identities

$$163 \sum_{i=0}^{4} \binom{8}{i} \tag{1}$$

$$\frac{1}{2}\left[4^4 + \binom{8}{4}\right] \tag{2}$$

$$\frac{1}{2}\left[4^4 + \sum_{i=0}^{4} \binom{4}{i}^2\right], \tag{3}$$

where $\binom{n}{k}$ is a binomial coefficient (Stoschek). An approximation due to Stoschek is given by

$$\pi \approx \frac{2^9}{163} = \frac{512}{163} \approx 3.1411043, \tag{4}$$

which is good to 3 digits.

196-Algorithm

Take any positive integer of two digits or more, reverse the digits, and add to the original number. Now repeat the procedure with the sum so obtained. This procedure quickly produces palindromic numbers for most integers. For example, starting with the number 5280 produces (5280, 6105, 11121, 23232). The end results of applying the algorithm to 1, 2, 3, ... are 1, 2, 3, 4, 5, 6, 7, 8, 9, 11, 11, 33, 44, 55, 66, 77, 88, 99, 121, ... (Sloane's A033865). The value for 89 is especially large, being 8813200023188.

The first few numbers not known to produce palindromes are 196, 887, 1675, 7436, 13783, ... (Sloane's A006960), which are simply the numbers obtained by iteratively applying the algorithm to the number 196. This number therefore lends itself to the name of the algorithm. In 1990, John Walker computed 2,415,836 iterations of the algorithm on 196 and obtained a number having 1,000,000 digits. This was extended in 1995 by Tim Irvin, who obtained a

number having 2,000,000 digits. The `rec.puzzles` archive states that a 3,924,257-digit nonpalindromic number is obtained after 9,480,000 iterations.

The number of terms $a(n)$ in the iteration sequence required to produce a PALINDROMIC NUMBER from (i.e., $a(n) = 1$ for a PALINDROMIC NUMBER, $a(n) = 2$ if a PALINDROMIC NUMBER is produced after a single iteration of the 196-algorithm, etc.) for , 2, ... are 1, 1, 1, 1, 1, 1, 1, 1, 1, 2, 1, 2, 2, 2, 2, 2, 2, 2, 3, 2, 2, 1, ... (Sloane's A030547). The smallest numbers which require, 1, 2, ... iterations to reach a palindrome are 0, 10, 19, 59, 69, 166, 79, 188, ... (Sloane's A023109).

The 196-algorithm can be implemented in *Mathematica* as

```
PalindromicQ[n_Integer?Positive]:= Module[
   {sn = ToString[n]},
   sn = = StringReverse[sn]
                                                    ]
Algorithm196[n_Integer?PalindromicQ,it_:0]:-
= {n}          Algorithm196[n_Integer?Positive,
it_:Infinity]: =
    FixedPointList[# + ToExpression[StringRe-
verse[ToString[#]]]&,
   n, it, SameTest- > (PalindromicQ[#2]&)
  ]
```

M. Sofroniou gives an efficient *Mathematica* implementation which has complexity $\mathcal{O}(k^2)$ for steps, requiring approximately 10.6 hours on a 450 MHz Pentium II to compute 250,000 iterations. Extrapolating the timing data suggests that approximately 42 days would be needed on this same machine to match Walker's 2,415,836 iterations.

239

Some interesting properties (as well as a few arcane ones not reiterated here) of the number 239 are discussed in Beeler *et al.* (1972, Item 63). 239 appears in MACHIN'S FORMULA

$$\tfrac{1}{4}\pi = 4\tan^{-1}\left(\tfrac{1}{5}\right) - \tan^{-1}\left(\tfrac{1}{239}\right),$$

which is related to the fact that

$$2 \cdot 13^4 - 1 = 239^2,$$

which is why 239/169 is the 7th CONVERGENT of $\sqrt{2}$. Another pair of INVERSE TANGENT FORMULAS involving 239 is

$$\tan^{-1}\left(\tfrac{1}{239}\right)\tan^{-1}\left(\tfrac{1}{70}\right) - \tan^{-1}\left(\tfrac{1}{99}\right)$$

$$\tan^{-1}\left(\tfrac{1}{408}\right) + \tan^{-1}\left(\tfrac{1}{577}\right).$$

239 needs 4 SQUARES (the maximum) to express it, 9 CUBES (the maximum, shared only with 23) to express it, and 19 fourth POWERS (the maximum) to express it (see WARING'S PROBLEM). However, 239 doesn't need the maximum number of fifth POWERS (Beeler *et al.* 1972, Item 63).

243

Feynman (1997) noticed the curious fact that the decimal expansion

$$\tfrac{1}{243} = 0.004115226337448559\ldots$$

repeats pairs of the digits 0, 1, 2, 3, ... separated by the digits 4, 5, 6, 7, ... Just after this point, the pattern breaks, since the fraction is given exactly by the repeating decimal

$$\tfrac{1}{243} = 0.\overline{004115226337448559670781893}.$$

This pattern is related to the fact that

$$\tfrac{1}{9} = 0.\bar{1}$$

and

$$\frac{1}{81} = 0.\overline{0123456789}.$$

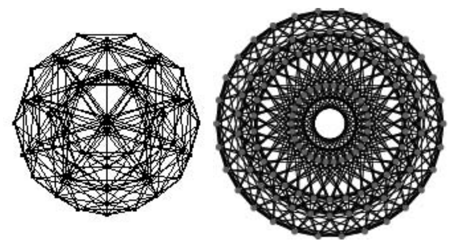
257-gon



257 is a FERMAT PRIME, and the 257-gon is therefore a CONSTRUCTIBLE POLYGON using COMPASS and STRAIGHTEDGE, as proved by Gauss. An illustration of the 257-gon is not included here, since its 257 segments so closely resemble a CIRCLE. Richelot and Schwendenwein found constructions for the 257-gon in 1832 (Coxeter 1969). De Temple (1991) gives a construction using 150 CIRCLES (24 of which are CARLYLE CIRCLES) which has GEOMETROGRAPHY symbol $94S_1 + 47S_2 + 275C_1 + 0C_2 + 150C_3$ and SIMPLICITY 566.

600-Cell

A finite regular 4-D POLYTOPE with SCHLÄFLI SYMBOL $\{3, 3, 5\}$. The 600-cell has 120 VERTICES (Coxeter 1969). In the plate following p. 160, Coxeter (1973) gives two illustrations of the polytope.

The dual of the 600-cell is the 120-CELL.

1729

1729 is sometimes called the HARDY-RAMANUJAN NUMBER. It is the smallest TAXICAB NUMBER, i.e., the smallest number which can be expressed as the sum of two cubes in two different ways:

$$1729 = 1^3 + 12^3 = 9^3 + 10^3.$$

See also HARDY-RAMANUJAN NUMBER, TAXICAB NUMBER

2187

The digits in the number 2187 form the two VAMPIRE NUMBERS: $21 \times 87 = 1827$ and $2187 = 27 \times 81$. 2187 is also given by 3^7.

See also VAMPIRE NUMBER

65537-gon

65537 is the largest known FERMAT PRIME, and the 65537-gon is therefore a CONSTRUCTIBLE POLYGON using COMPASS and STRAIGHTEDGE, as proved by Gauss. The 65537-gon has so many sides that it is, for all intents and purposes, indistinguishable from a CIRCLE using any reasonable printing or display methods.

Hermes spent 10 years on the construction of the 65537-gon at Königsberg around (1900). After the Second World War, his manuscripts were moved to the Mathematical Institute in Göttingen, where they can now be viewed (Coxeter 1969).

De Temple (1991) notes that a GEOMETRIC CONSTRUCTION can be done using 1332 or fewer CARLYLE CIRCLES.

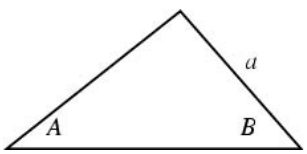
A

AAA Theorem



Specifying three ANGLES A, B, and C does not uniquely define a TRIANGLE, but any two TRIANGLES with the same ANGLES are SIMILAR. Specifying two ANGLES of a TRIANGLE automatically gives the third since the sum of ANGLES in a TRIANGLE sums to $180°$ (π RADIANS), i.e.,

$$C = \pi - A - B.$$

See also AAS THEOREM, ASA THEOREM, ASS THEOREM, SAS THEOREM, SSS THEOREM, TRIANGLE

AAS Theorem

Specifying two angles A and B and a side a uniquely determines a TRIANGLE with AREA

$$K = \frac{a^2 \sin B \sin C}{2 \sin A} = \frac{a^2 \sin B \sin(\pi - A - B)}{2 \sin A}. \quad (1)$$

The third angle is given by

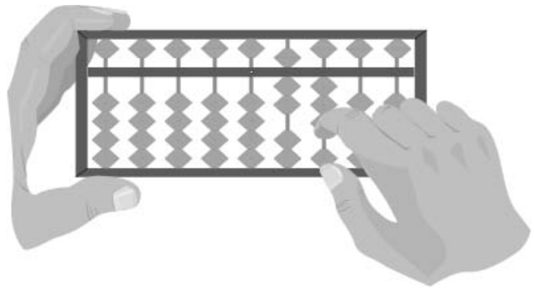
$$C = \pi - A - B, \quad (2)$$

since the sum of angles of a TRIANGLE is $180°$ (π RADIANS). Solving the LAW OF SINES

$$\frac{a}{\sin A} = \frac{b}{\sin B} \quad (3)$$

for b gives

$$b = a \frac{\sin B}{\sin A}. \quad (4)$$



Finally,

$$c = b \cos A + a \cos B = a(\sin B \cot A + \cos B) \quad (5)$$

$$= a \sin B(\cot A + \cot B). \quad (6)$$

Abacus

A mechanical counting device consisting of a frame holding a series of parallel rods on each of which beads are strung. Each bead represents a counting unit, and each rod a place value. The primary purpose of the abacus is not to perform actual computations, but to provide a quick means of storing numbers during a calculation. Abaci were used by the Japanese and Chinese, as well as the Romans.

abc Conjecture

A CONJECTURE due to J. Oesterlé and D. W. Masser. It states that, for any INFINITESIMAL $\epsilon > 0$, there exists a CONSTANT C_ϵ such that for any three RELATIVELY PRIME INTEGERS a, b, c satisfying

$$a + b = c, \quad (1)$$

the INEQUALITY

$$\max(|a|, |b|, |c|) \leq C_\epsilon \prod_{p|abc} p^{1+\epsilon} \quad (2)$$

holds, where $p|abc$ indicates that the PRODUCT is over PRIMES p which DIVIDE the PRODUCT abc. If this CONJECTURE were true, it would imply FERMAT'S LAST THEOREM for sufficiently large POWERS (Goldfeld 1996). This is related to the fact that the abc conjecture implies that there are at least $C \ln x$ WIEFERICH PRIMES $\leq x$ for some constant C (Silverman 1988, Vardi 1991).

The conjecture can also be stated by defining the height and radical of the sum $P: a + b = c$ as

$$h(P) = \max\{\ln|a|, \ln|b|, \ln|c|\} \tag{3}$$

$$r(P) = \sum_{p|abc} \ln p, \tag{4}$$

where p runs over all prime divisors of a, b, and c. Then the abc conjecture states that for all $\epsilon > 0$, there exists a constant K such that for all $P: a+b+c$,

$$h(P) \leq r(P) + \epsilon h(P) + K \tag{5}$$

(van Frankenhuysen 2000). van Frankenhuysen (2000) has shown that there exists an infinite sequence of sums $P: a+b=c$ or RATIONAL INTEGERS with large height compared to the radical,

$$h(p) \geq r(P) + 4K_l \frac{\sqrt{h(P)}}{\ln[h(P)]}, \tag{6}$$

with

$$K_l = 2^{l/2}\left(\frac{2\pi}{e}\right)^{1/4} > 1.517 \tag{7}$$

for $l = 0.5990$, improving a result of Stewart and Tijdeman (1986).

Abel Polynomial

A polynomial $A_n(x; a)$ given by the associated SHEFFER SEQUENCE with

$$f(t) = te^{at}, \tag{1}$$

given by

$$A_n(x;\ a) = x(x - an)^{n-1}. \tag{2}$$

The GENERATING FUNCTION is

$$\sum_{k=0}^{\infty} \frac{A_k(x;\ a)}{k!} t^k = e^{xW(at)/a}, \tag{3}$$

where $W(x)$ is LAMBERT'S W-FUNCTION. The associated BINOMIAL IDENTITY is

$$(x+y)(x+y-an)^{n-1} = \sum_{k=0}^{n} \binom{n}{k} xy(x-ak)^{k-1}[y - a(n-k)]^{n-k-1}, \tag{4}$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT, a formula originally due to Abel (Riordan 1979, p. 18; Roman 1984, pp. 30 and 73).

The first few Abel polynomials are

$$\begin{aligned} A_0(x;\ a) &= 1 \\ A_1(x;\ a) &= x \\ A_2(x;\ a) &= x(x-2a) \\ A_3(x;\ a) &= x(x-3a)^2 \\ A_4(x;\ a) &= x(x-4a)^3. \end{aligned}$$

Abel Transform

The following INTEGRAL TRANSFORM relationship, known as the Abel transform, exists between two functions $f(x)$ and $g(t)$ for $0 < \alpha < 1$,

$$f(x) = \int_0^x \frac{g(t)\, dt}{(x-t)^{\alpha}} \tag{1}$$

$$g(t) = -\frac{\sin(\pi\alpha)}{\pi} \frac{d}{dt} \int_0^t \frac{f(x)\, dx}{(x-t)^{1-\alpha}} \tag{2}$$

$$= -\frac{\sin(\pi\alpha)}{\pi}\left[\int_0^t \frac{df}{dx} \frac{dx}{(t-x)^{1-\alpha}} + \frac{f(0)}{t^{1-\alpha}}\right]. \tag{3}$$

The Abel transform is used in calculating the radial

mass distribution of galaxies (Binney and Tremaine 1987) and inverting planetary radio occultation data to obtain atmospheric information as a function of height.

Bracewell (1999, p. 262) defines a slightly different form of the Abel transform given by

$$g(x) = \mathscr{A}[f(r)] = 2\int_x^\infty \frac{f(r)r\,dr}{\sqrt{r^2 - x^2}}. \quad (4)$$

The following table gives a number of common Abel transform pairs (Bracewell 1999, p. 264). Here,

$$\Pi_a(x) \equiv \Pi\left(\frac{x}{2a} - \frac{1}{2}\right) = \begin{cases} 1 & \text{for } 0 < x < 0 \\ 0 & \text{otherwise} \end{cases} \quad (5)$$

where $\Pi(x)$ is the RECTANGLE FUNCTION, and

$$M(x) = 2\pi\left[x^{-3}\int_0^x J_0(x)\,dx - x^{-2}J_0(x)\right] \quad (6)$$

$$= \frac{\pi^2}{x^2}\left[J_1(x)\mathscr{H}_0(x) - J_0(x)\mathscr{H}_1(x)\right], \quad (7)$$

where $J_n(x)$ is a BESSEL FUNCTION OF THE FIRST KIND and $\mathscr{H}_n(x)$ is a STRUVE FUNCTION.

$f(r)$	$g(x)$	conditions
$\Pi_a(r)$	$2\sqrt{a^2 - x^2}$	$a^2 > x^2$
$(a^2 - r^2)^{-1/2}\Pi_a(r)$	π	$a^2 > x^2$
$\sqrt{a^2 - r^2}\Pi_a(r)$	$\frac{1}{2}\pi(a^2 - x^2)$	$a^2 > x^2$
$(a^2 - r^2)\Pi_a(r)$	$\frac{4}{3}(a^2 - x^2)^{3/2}$	$a^2 > x^2$
$(a^2 - r^2)^{3/2}\Pi_a(r)$	$\frac{3}{8}\pi(a^2 - x^2)^2$	$a^2 > x^2$
$(a - r)\Pi_a(r)$	$a\sqrt{a^2 - x^2} - x^2\cosh^{-1}\left(\frac{a}{x}\right)$	
$\frac{1}{\pi}\cosh^{-1}\left(\frac{a}{r}\right)$	$a - x$	
$\delta(r - a)$	$\frac{2a}{\sqrt{a^2 - x^2}}\Pi_a(x)$	
e^{-r^2/σ^2}	$\sigma\sqrt{\pi}e^{-x^2/\sigma^2}$	$\sigma > 0$
$r^2 e^{-r^2/\sigma^2}$	$\sigma(x^2 + \frac{1}{2}\sigma^2)\sqrt{\pi}e^{-x^2/\sigma^2}$	$\sigma > 0$
$\frac{e^{-r^2/\sigma^2}}{\sigma\sqrt{\pi}}(r^2 - \frac{1}{2}\sigma^2)$	$x^2 e^{-x^2/\sigma^2}$	$\sigma > 0$
$\frac{1}{b^2 + r^2}$	$\frac{\pi}{\sqrt{b^2 + r^2}}$	$b^2 + x^2 > 0$
$J_0(\omega r)$	$\frac{2\cos(\omega x)}{\omega}$	$\omega > 0$
$M(r)$	$\frac{8\pi^4}{\omega^2 x^2}\sin^2\left(\frac{x\omega}{2\pi}\right)$	$\omega > 0$

Abel's Convergence Theorem

Given a TAYLOR SERIES

$$f(z) = \sum_{n=0}^{\infty} C_n z^n = \sum_{n=0}^{\infty} C_n r^n e^{in\theta}, \quad (1)$$

where the COMPLEX NUMBER z has been written in the polar form $z = re^{i\theta}$, examine the REAL and IMAGINARY PARTS

$$u(r, \theta) = \sum_{n=0}^{\infty} C_n r^n \cos(n\theta) \quad (2)$$

$$v(r, \theta) = \sum_{n=0}^{\infty} C_n r^n \sin(n\theta). \quad (3)$$

Abel's theorem states that, if $u(1, \theta)$ and $v(1, \theta)$ are CONVERGENT, then

$$u(1, \theta) + iv(1, \theta) = \lim_{r \to 1} f(re^{i\theta}). \quad (4)$$

Stated in words, Abel's theorem guarantees that, if a REAL POWER SERIES CONVERGES for some POSITIVE value of the argument, the DOMAIN of UNIFORM CONVERGENCE extends at least up to and including this point. Furthermore, the continuity of the sum function extends at least up to and including this point.

Abel's Curve Theorem

The sum of the values of an INTEGRAL of the "first" or "second" sort

$$\int_{x_0,\,y_0}^{x_1,\,y_1} \frac{P\,dx}{Q} + \ldots + \int_{x_0,\,y_0}^{x_N,\,y_N} \frac{P\,dx}{Q} = F(z)$$

and

$$\frac{P(x_1,\,y_1)}{Q(x_1,\,y_1)}\frac{dx_1}{dz} + \ldots + \frac{P(x_N,\,y_N)}{Q(x_N,\,y_N)}\frac{dx_N}{dz} = \frac{dF}{dz},$$

from a FIXED POINT to the points of intersection with a curve depending rationally upon any number of parameters is a RATIONAL FUNCTION of those parameters.

References

Coolidge, J. L. *A Treatise on Algebraic Plane Curves.* New York: Dover, p. 277, 1959.

Abel's Differential Equation

The Abel equation of the first kind is given by

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2 + f_3(x)y^3 + \ldots$$

(Murphy 1960, p. 23; Zwillinger 1997, p. 120), and the Abel equation of the second kind by

$$[g_0(x) + g_1(x)y]y' = f_0(x) + f_1(x)y + f_2(x)y^2 + f_3(x)y^3$$

(Murphy 1960, p. 25; Zwillinger 1997, p. 120).

References

Murphy, G. M. *Ordinary Differential Equations and Their Solution.* Princeton, NJ: Van Nostrand, 1960.
Zwillinger, D. *Handbook of Differential Equations, 3rd ed.* Boston, MA: Academic Press, p. 120, 1997.

Abel's Differential Equation Identity

Given a homogeneous linear SECOND-ORDER ORDINARY DIFFERENTIAL EQUATION,

$$y'' + P(x)y' + Q(x)y = 0, \tag{1}$$

call the two linearly independent solutions $y_1(x)$ and $y_2(x)$. Then

$$y_1'' + P(x)y_1' + Q(x)y_1 = 0 \tag{2}$$

$$y_2'' + P(x)y_2' + Q(x)y_2 = 0. \tag{3}$$

Now, take $y_1 \times$ (3) minus $y_2 \times$ (2),

$$y_1[y_2'' + P(x)y_2' + Q(x)y_2] - y_2[y_1'' + P(x)y_1' + Q(x)y_1] = 0 \tag{4}$$

$$(y_1y_2'' - y_2y_1'') + P(y_1y_2' - y_1'y_2) + Q(y_1y_2 - y_1y_2) = 0 \tag{5}$$

$$(y_1y_2'' - y_2y_1'') + P(y_1y_2' - y_1'y_2) = 0. \tag{6}$$

Now, use the definition of the WRONSKIAN and take its DERIVATIVE,

$$W \equiv y_1y_2' + y_1'y_2 \tag{7}$$

$$W' = (y'y_2' + y_1y_2'') - (y_1'y_2' + y_1''y_2)$$

$$y_1y_2'' - y_1''y_2. \tag{8}$$

Plugging W and W' into (6) gives

$$W' + PW = 0. \tag{9}$$

This can be rearranged to yield

$$\frac{dW}{W} = -P(x)\,dx \tag{10}$$

which can then be directly integrated to

$$\ln\left[\frac{W(x)}{W_0}\right] = -\int P(x)\,dx, \tag{11}$$

where $\ln x$ is the NATURAL LOGARITHM. Exponentiating then yields Abel's identity

$$W(x) = W_0 e^{-\int P(x)\,dx}, \tag{12}$$

where W_0 is a constant of integration.

Abel's Duplication Formula

The duplication formula for ROGERS L-FUNCTION follows from ABEL'S FUNCTIONAL EQUATION and is given by

$$\tfrac{1}{2}L(x^2) = L(x) - L\left(\frac{x}{1+x}\right).$$

See also ABEL'S FUNCTIONAL EQUATION, DILOGARITHM

References

Gordon, B. and McIntosh, R. J. "Algebraic Dilogarithm Identities." *Ramanujan J.* **1**, 431–48, 1997.

Abel's Functional Equation

Let $L(x)$ denote the ROGERS L-FUNCTION defined in terms of the usual DILOGARITHM by

$$L(x) = \frac{6}{\pi^2}\left[\mathrm{Li}_2(x) + \tfrac{1}{2}\ln x \ln(1-x)\right]$$

$$= \frac{6}{\pi^2}\left[\sum_{n=1}^{\infty}\frac{x^n}{n^2} + \tfrac{1}{2}\ln x \ln(1-x)\right],$$

then $L(x)$ satisfies the functional equation

$$L(x) + L(y) = L(xy) + L\left(\frac{x(1-y)}{1-xy}\right) + L\left(\frac{y(1-x)}{1-xy}\right).$$

ABEL'S DUPLICATION FORMULA follows from this identity.

Abel's Inequality

Let $\{f_n\}$ and $\{a_n\}$ be SEQUENCES with $f_n \geq f_{n+1} > 0$ for $n = 1, 2, \ldots$, then

$$\left|\sum_{n=1}^{m} a_n f_n\right| \leq A f_1,$$

where

$$A = \max\{|a_1|,\ |a_1 + a_2|, \ldots, |a_1 + a_2 + \ldots + a_m|\}.$$

Abel's Irreducibility Theorem

If one ROOT of the equation $f(x) = 0$, which is irreducible over a FIELD K, is also a ROOT of the equation $F(x) = 0$ in K, then all the ROOTS of the irreducible equation $f(x) = 0$ are ROOTS of $F(x) = 0$. Equivalently, $F(x)$ can be divided by $f(x)$ without a REMAINDER,

$$F(x) = f(x)F_1(x),$$

where $F_1(x)$ is also a POLYNOMIAL over K.

Abelian Differential

An Abelian differential is an ANALYTIC or MEROMORPHIC DIFFERENTIAL on a COMPACT or closed RIEMANN SURFACE.

Abelian Extension

This entry contributed by NICOLAS BRAY

If F is an ALGEBRAIC GALOIS EXTENSION of K such that the GALOIS GROUP of the extension is ABELIAN, then F is said to be an Abelian extension of K.

See also ALGEBRAIC EXTENSION, GALOIS EXTENSION, GALOIS GROUP

Abelian Function

An INVERSE FUNCTION of an ABELIAN INTEGRAL. Abelian functions have two variables and four periods, and can be defined by

$$\Theta\left(\upsilon,\ \tau;\ \begin{matrix} q' \\ q \end{matrix}\right) = \sum_{\lambda=-\infty}^{\infty} 2^{2\pi i \upsilon(\lambda+q') + \pi i \tau(\lambda+q')^2 + 2\pi i q(\lambda+q')}$$

Baker (1907, p. 21). Abelian functions are a generalization of ELLIPTIC FUNCTIONS, and are also called hyperelliptic functions.

Abelian Group

N.B. A detailed online essay by S. Finch was the starting point for this entry.

A GROUP for which the elements COMMUTE (i.e., $AB = BA$ for all elements A and B) is called an Abelian group. All CYCLIC GROUPS are Abelian, but an Abelian group is not necessarily CYCLIC. All SUBGROUPS of an Abelian group are NORMAL. In an Abelian group, each element is in a CONJUGACY CLASS by itself, and the CHARACTER TABLE involves POWERS of a single element known as a GENERATOR.

No general formula is known for giving the number of nonisomorphic FINITE GROUPS of a given ORDER. However, the number of nonisomorphic Abelian FINITE GROUPS $a(n)$ of any given ORDER n is given by writing n as

$$n=\prod_i p_i^{\alpha_i}, \quad (1)$$

where the p_i are distinct PRIME FACTORS, then

$$a(n)=\prod_i P(\alpha_i), \quad (2)$$

where $P(k)$ is the PARTITION FUNCTION. This gives 1, 1, 1, 2, 1, 1, 1, 3, 2, ... (Sloane's A000688). The smallest orders for which $n = 1, 2, 3, \ldots$ nonisomorphic Abelian groups exist are 1, 4, 8, 36, 16, 72, 32, 900, 216, 144, 64, 1800, 0, 288, 128, ... (Sloane's A046056), where 0 denotes an impossible number (i.e., not a product of partition numbers) of nonisomorphic Abelian, groups. The "missing" values are 13, 17, 19, 23, 26, 29, 31, 34, 37, 38, 39, 41, 43, 46, ... (Sloane's A046064). The incrementally largest numbers of Abelian groups as a function of order are 1, 2, 3, 5, 7, 11, 15, 22, 30, 42, 56, 77, 101, ... (Sloane's A046054), which occur for orders 1, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 2048, 4096, 8192, ... (Sloane's A046055).

The KRONECKER DECOMPOSITION THEOREM states that every FINITE Abelian group can be written as a GROUP DIRECT PRODUCT of CYCLIC GROUPS of PRIME POWER ORDER. If the ORDER of a FINITE GROUP is a PRIME p, then there exists a single Abelian group of order p (denoted $\mathbb{Z}_p$) and no non-Abelian groups. If the ORDER is a prime squared p^2 then there are two Abelian groups (denoted $\mathbb{Z}_{p^2}$ and $\mathbb{Z}_p \times \mathbb{Z}_p$. If the ORDER is a prime cubed p^3, then there are three Abelian groups (denoted $\mathbb{Z}_p \times \mathbb{Z}_p \times \mathbb{Z}_p$, $\mathbb{Z}_p \times \mathbb{Z}_{p^2}$, and $\mathbb{Z}_{p^3}$), and five groups total. If the order is a PRODUCT of two primes p and q, then there exists exactly one Abelian group of ORDER pq (denoted $\mathbb{Z}_p \times \mathbb{Z}_q$).

Another interesting result is that if $a(n)$ denotes the number of nonisomorphic Abelian groups of ORDER n, then

$$\sum_{n=1}^{\infty} a(n)n^{-s}=\zeta(s)\zeta(2s)\zeta(3s)\cdots, \quad (3)$$

where $\zeta(s)$ is the RIEMANN ZETA FUNCTION. Srinivasan (1973) has also shown that

$$\sum_{n=1}^{N} a(n)=A_1N+A_2N^{1/2}+A_3N^{1/3} + \mathcal{O}[x^{105/407}(\ln x)^2], \quad (4)$$

where

$$A_k\equiv\prod_{\substack{j=1\\ j\neq k}}^{\infty}\zeta\left(\frac{j}{k}\right)=\begin{cases}2.294856591\ldots & \text{for } k=1\\ -14.6475663\ldots & \text{for } k=2\\ 118.6924619\ldots & \text{for } k=3,\end{cases} \quad (5)$$

and $\zeta(s)$ is again the RIEMANN ZETA FUNCTION. [Richert (1952) incorrectly gave $A_3=114$.] DeKoninck and Ivic (1980) showed that

$$\sum_{n=1}^{N}\frac{1}{a(n)}=BN+\mathcal{O}[\sqrt{N}(\ln N)^{-1/2}], \quad (6)$$

where

$$B\equiv\prod\left\{1-\sum_{k=2}^{\infty}\left[\frac{1}{P(k-2)}-\frac{1}{P(k)}\right]\frac{1}{p^k}\right\}=0.752\ldots \quad (7)$$

is a product over PRIMES. Bounds for the number of nonisomorphic non-Abelian groups are given by Neumann (1969) and Pyber (1993).

Abelian Integral

An INTEGRAL OF THE FORM

$$\int_0^x \frac{dt}{\sqrt{R(t)}},$$

where $R(t)$ is a POLYNOMIAL of degree > 4. They are also called HYPERELLIPTIC INTEGRALS.

See also ABELIAN FUNCTION, ELLIPTIC INTEGRAL

References

Siegel, C. L. *Topics in Complex Function Theory, Vol. 2: Automorphic Functions and Abelian Integrals.* New York: Wiley, 1988.

Abelian Theorem

A theorem which asserts that if a sequence or function behaves regularly, then some average of it behaves regularly. For example,

$$A(x) \sim x$$

implies

$$A_1(x) = \int_0^x A(t)\, dt \sim \tfrac{1}{2}x^2$$

for any $A(x)$. The converse is false, but can be made into a correct TAUBERIAN THEOREM if $A(x)$ is subjected to an appropriate additional condition (Hardy 1999, p. 46).

See also TAUBERIAN THEOREM

Abelianization

In general, groups are not ABELIAN. However, there is always a GROUP HOMOMORPHISM $h : G \to G'$ to an ABELIAN GROUP, and this homomorphism is called Abelianization. The homomorphism is abstractly described by its kernel, the COMMUTATOR SUBGROUP $[G, G]$. So $G' = G/[G, G]$. Roughly speaking, in any expression, every product becomes commutative after Abelianization. As a consequence, some previously unequal expressions may become equal, or even represent the IDENTITY ELEMENT.

For example, in the eight-element QUATERNION GROUP $G = \{\pm 1, \pm i, \pm j, \pm k\}$, the COMMUTATOR SUBGROUP is $\{\pm 1\}$. The Abelianization of G is a copy of $\mathbb{Z}_2 \times \mathbb{Z}_2$, and for instance, $i'j' = j'i'$ in the Abelianization.

See also ABELIAN, GROUP, HOMOMORPHISM

Abel-Plana Formula

This entry contributed by DAVID ANDERSON

The Abel-Plana formula gives an expression for the difference between a discrete sum and the corresponding integral. The formula can be derived from the ARGUMENT PRINCIPLE

$$\oint_\gamma f(z)\frac{g'(z)}{g(z)}\, dz = \sum_n f(\mu_n) - \sum_m f(\nu_m), \tag{1}$$

where μ_n are the zeros of $g(z)$ and ν_m are the poles contained within the CONTOUR γ. An appropriate choice of g and γ then yields

$$\sum_{n=0}^{\infty} f(n) - \int_0^\infty f(x)\, dx = \tfrac{1}{2}f(0) - \tfrac{1}{2}\int_0^\infty [f(it) - f(-it)][\cot(\pi i t) + i]\, dt, \tag{2}$$

or equivalently

$$\sum_{n=0}^{\infty} f(n) - \int_0^\infty f(x)\, dx = \tfrac{1}{2}f(0) + i\int_0^\infty \frac{f(it) - f(-it)}{e^{2\pi t} - 1} dt. \tag{3}$$

The formula is particularly useful in Casimir effect calculations involving differences between quantized modes and free modes.

See also ARGUMENT PRINCIPLE

Abhyankar's Conjecture

For a FINITE GROUP G, let $p(G)$ be the SUBGROUP generated by all the SYLOW P-SUBGROUPS of G. If X is a projective curve in characteristic $p > 0$, and if x_0, ..., x_t are points of X (for $t > 0$), then a NECESSARY and SUFFICIENT condition that G occur as the GALOIS GROUP of a finite covering Y of X, branched only at the points x_0, ..., x_t, is that the QUOTIENT GROUP $G/p(G)$ has $2g + t$ generators.

Raynaud (1994) solved the Abhyankar problem in the crucial case of the affine line (i.e., the projective line with a point deleted), and Harbater (1994) proved the full Abhyankar conjecture by building upon this special solution.

Abs

ABSOLUTE VALUE

Abscissa

The x- (horizontal) coordinate of a point in a two dimensional coordinate system. Physicists and astronomers sometimes use the term to refer to the axis itself instead of the distance along it.

See also AXIS, ORDINATE, REAL LINE, x-AXIS, y-AXIS, z-AXIS

Absolute Convergence

A SERIES $\Sigma_n u_n$ is said to CONVERGE absolutely if the SERIES $\Sigma_n |u_n|$ CONVERGES, where $|u_n|$ denotes the ABSOLUTE VALUE. If a SERIES is absolutely convergent, then the sum is independent of the order in which terms are summed. Furthermore, if the SERIES is multiplied by another absolutely convergent series, the product series will also converge absolutely.

See also CONDITIONAL CONVERGENCE, CONVERGENT SERIES, RIEMANN SERIES THEOREM

Absolute Pseudoprime

CARMICHAEL NUMBER

Absolute Square

Also known as the squared norm. The absolute square of a COMPLEX NUMBER z is written $|z|^2$, where $|z|$ is the MODULUS and is defined as

$$|z|^2 \equiv z\bar{z}, \tag{1}$$

where $\bar{z}$ denotes the COMPLEX CONJUGATE of z. For a REAL NUMBER, (1) simplifies to

$$|z|^2 = z^2. \tag{2}$$

If the COMPLEX NUMBER is written $z = x + iy$, then the absolute square can be written

$$|x+iy|^2 = x^2 + y^2. \tag{3}$$

An absolute square can be computed in terms of x and y using the *Mathematica* command `ComplexExpand[Abs[z]2, TargetFunctions- > {Conjugate}]`.

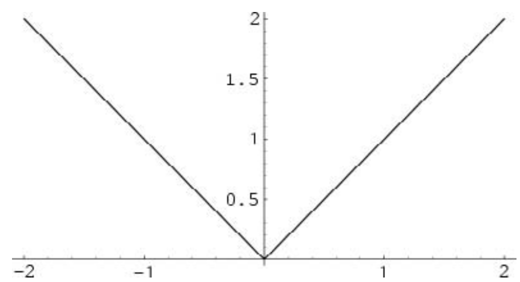
An important identity involving the absolute square is given by

$$\begin{aligned}\left|a \pm be^{-i\delta}\right|^2 &= (a \pm be^{-i\delta})(a \pm be^{i\delta})\\ &= a^2 + b^2 \pm ab(e^{i\delta} + e^{-i\delta}) = a^2 + b^2 \pm 2ab\cos\delta. \end{aligned} \tag{4}$$

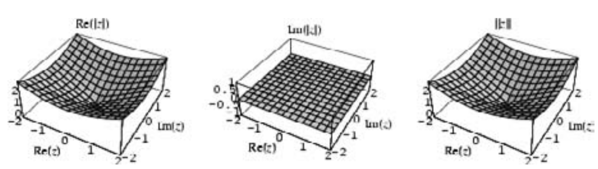
If $a = 1$, then (4) becomes

$$\begin{aligned}\left|1 \pm be^{-i\delta}\right|^2 &= 1 + b^2 \pm 2b\cos\delta\\ &= (1 \pm b)^2 \mp 4b\sin^2(\tfrac{1}{2}\delta).\end{aligned} \tag{5}$$

If $a = 1$, and $b = 1$, then



$$\left|1 - e^{-i\delta}\right|^2 = 4\sin^2(\tfrac{1}{2}\delta). \tag{6}$$



Finally,

$$\begin{aligned}|e^{i\phi_1} + e^{i\phi_2}|^2 &= (e^{i\phi_1} + e^{i\phi_2})(e^{-i\phi_1} + e^{-i\phi_2})\\ &= 2[1 + \cos(\phi_2 - \phi_1)]\\ &= 4\cos^2[\tfrac{1}{2}(\phi_2 - \phi_1)].\end{aligned} \tag{7}$$

See also ARGUMENT (COMPLEX NUMBER), COMPLEX NUMBER, MODULUS (COMPLEX NUMBER)

Absolute Value

The absolute value of a REAL NUMBER x is denoted $|x|$ and given by the "unsigned" portion of x,

$$|x| = x\,\mathrm{sgn}(x) = \begin{cases} -x & \text{for } x \le 0\\ x & \text{for } x \ge 0,\end{cases}$$

where $\mathrm{sgn}\, x$ is the sign function SGN. The absolute value is therefore always greater than or equal to 0. The same notation is used to denote the MODULUS of a COMPLEX NUMBER $z = x + iy$, $|z| \equiv \sqrt{x^2 + y^2}$, a P-ADIC NORM, or a general VALUATION. The NORM of a VECTOR $\mathbf{x}$ is also denoted $|x|$, although $|x|$ is more commonly used.

Other NOTATIONS similar to the absolute value are the FLOOR FUNCTION $\lfloor\lfloor x \rfloor\rfloor$, NINT function $[x]$, and CEILING FUNCTION $\lceil\lceil x \rceil\rceil$.

The integral of the absolute value of the different of two variables is given by

$$\int_0^1\int_0^1 |x-y|^n dx\, dy = \frac{2}{(n+1)(n+2)},$$

which has values 1/3, 1/6, 1/10, 1/15, 1/21, ... for $n = 1$, 2, ..., i.e., the inverses of the TRIANGULAR NUMBERS (Sloane's A000217).

Absolutely Continuous

A MEASURE λ is absolutely continuous with respect to another measure μ if $\lambda(E) = 0$ for every set with $\mu(E) = 0$. This makes sense as long as μ is a POSITIVE MEASURE, such as LEBESGUE MEASURE, but λ can be any measure, possibly a COMPLEX MEASURE.

By the RADON-NIKODYM THEOREM, this is equivalent to saying that

$$\lambda(E) = \int_E f\, d\mu$$

where the integral is the LEBESGUE INTEGRAL, for some INTEGRABLE function f. The function f is like a derivative, and is called the RADON-NIKODYM DERIVATIVE $d\lambda/d\mu$.

The measure supported at 0 ($\mu^{(E)} = 1$ iff $0 \in E$) is not absolutely continuous with respect to LEBESGUE MEASURE, and is a SINGULAR MEASURE.

Absolutely Fair

A sequence of random variates X_0, X_1, ... is called absolutely fair if for $n = 1, 2, ...$,

$$(X_1) = 0$$

and

$$(X_{n+1}|X_1, \ldots, X_n) = 0$$

(Feller 1971, p. 210).

Absolutely Monotonic Function

This entry contributed by RONALD M. AARTS

A function $f(x)$ is absolutely monotonic in the interval $a < x < b$ if it has nonnegative derivatives of all orders in the region, i.e.,

$$f^{(k)}(x) \geq 0 \tag{1}$$

for $a < x < b$ and $k = 0, 1, 2, ...$ For example, the functions

$$f(x) = -\ln(-x) \quad (-1 \leq x < 0) \tag{2}$$

and

$$f(x) = \sin^{-1} x \quad (0 \leq x \leq 1) \tag{3}$$

are absolutely monotonic functions (Widder 1941).

Abstract Manifold

An abstract manifold is a MANIFOLD in the context of an abstract space with no particular embedding, or representation in mind. It is a TOPOLOGICAL SPACE with an ATLAS of COORDINATE CHARTS.

For example, the SPHERE $\mathbb{S}^2$ can be considered a SUBMANIFOLD of $\mathbb{R}^3$ or a QUOTIENT SPACE $O(3)/O(2)$. But as an abstract manifold, it is just a MANIFOLD, which can be covered by two coordinate charts $\phi_1 : \mathbb{R}^2 \to \mathbb{S}^2$ and $\phi_2 : \mathbb{R}^2 \to \mathbb{S}^2$, with the single TRANSITION FUNCTION,

$$\phi_2^{-1} \circ \phi_1 : \mathbb{R}^2 - (0,\ 0) \to \mathbb{R}^2 - (0,\ 0)$$

defined by

$$\phi_2^{-1} \circ \phi_1(x,\ y) = (x/r^2,\ y/r^2)$$

where $r^2 = x^2 + y^2$. It can also be thought of as two disks glued together at their boundary.

LAMBDA CALCULUS

Abundance

The abundance of a number n is the quantity

$$A(n) \equiv \sigma(n) - 2n,$$

where $\sigma(n)$ is the DIVISOR FUNCTION. Kravitz has conjectured that no numbers exist whose abundance is an ODD SQUARE (Guy 1994).

The following table lists special classifications given to a number n based on the value of $A(n)$.

$A(n)$	Number
< 0	DEFICIENT NUMBER
-1	ALMOST PERFECT NUMBER
0	PERFECT NUMBER
1	QUASIPERFECT NUMBER
> 0	ABUNDANT NUMBER

See also ABUNDANCY, DEFICIENCY

References

Guy, R. K. *Unsolved Problems in Number Theory, 2nd ed.* New York: Springer-Verlag, pp. 45–6, 1994.

Abundancy

The ratio $\sigma(n)/n$, where $\sigma(n)$ is the DIVISOR FUNCTION.

See also ABUNDANCE, ABUNDANT NUMBER

References

Guy, R. K. "The Second Strong Law of Small Numbers." *Math. Mag.* **63**, 3–0, 1990.

Abundant Number

An abundant number is an INTEGER n which is not a PERFECT NUMBER and for which

$$s(n) \equiv \sigma(n) - n > n, \tag{1}$$

where $\sigma(n)$ is the DIVISOR FUNCTION. The quantity $\sigma(n) - 2n$ is sometimes called the ABUNDANCE. The first few abundant numbers are 12, 18, 20, 24, 30, 36, ... (Sloane's A005101). Abundant numbers are sometimes called EXCESSIVE NUMBERS.

There are only 21 abundant numbers less than 100, and they are all EVEN. The first ODD abundant number is

$$945 = 3^3 \cdot 7 \cdot 5. \tag{2}$$

That 945 is abundant can be seen by computing

$$s(945) = 975 > 945. \tag{3}$$

Any multiple of a PERFECT NUMBER or an abundant number is also abundant. Every number greater than 20161 can be expressed as a sum of two abundant numbers.

Define the density function

$$A(x) \equiv \lim_{n\to\infty} \frac{|\{n : \sigma(n) \geq xn\}|}{n} \tag{4}$$

for a POSITIVE REAL NUMBER x, then Davenport (1933) proved that $A(x)$ exists and is continuous for all x, and Erdos (1934) gave a simplified proof (Finch). Wall (1971) and Wall *et al.* (1977) showed that

$$0.2441 < A(2) < 0.2909, \tag{5}$$

and Deléglise (1998) showed that

$$0.2474 < A(2) < 0.2480. \quad (6)$$

A number which is abundant but for which all its PROPER DIVISORS are DEFICIENT is called a PRIMITIVE ABUNDANT NUMBER (Guy 1994, p. 46).

Acceleration

Let a particle travel a distance $s(t)$ as a function of time t (here, s can be thought of as the ARC LENGTH of the curve traced out by the particle). The SPEED (the SCALAR NORM of the VECTOR VELOCITY) is then given by

$$\frac{ds}{dt} = \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 + \left(\frac{dz}{dt}\right)^2}. \quad (1)$$

The acceleration is defined as the time DERIVATIVE of the VELOCITY, so the SCALAR acceleration is given by

$$a \equiv \frac{dv}{dt} \quad (2)$$

$$= \frac{d^2s}{dt^2} \quad (3)$$

$$= \frac{\frac{dx}{dt}\frac{d^2x}{dt^2} + \frac{dy}{dt}\frac{d^2y}{dt^2} + \frac{dz}{dt}\frac{d^2z}{dt^2}}{\sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 + \left(\frac{dz}{dt}\right)^2}} \quad (4)$$

$$= \frac{dx}{ds}\frac{d^2x}{dt^2} + \frac{dy}{ds}\frac{d^2y}{dt^2} + \frac{dz}{ds}\frac{d^2z}{dt^2} \quad (5)$$

$$= \frac{d\mathbf{r}}{ds} \cdot \frac{d^2\mathbf{r}}{dt^2}. \quad (6)$$

The VECTOR acceleration is given by

$$\mathbf{a} \equiv \frac{d\mathbf{v}}{dt} = \frac{d^2\mathbf{r}}{dt^2} = \frac{d^2s}{dt^2}\hat{\mathbf{T}} + \kappa\left(\frac{ds}{dt}\right)^2\hat{\mathbf{N}}, \quad (7)$$

where $\hat{\mathbf{T}}$ is the UNIT TANGENT VECTOR, κ the CURVATURE, s the ARC LENGTH, and $\hat{\mathbf{N}}$ the UNIT NORMAL VECTOR.

Let a particle move along a straight LINE so that the positions at times t_1, t_2, and t_3 are s_1, s_2, and s_3, respectively. Then the particle is uniformly accelerated with acceleration a IFF

$$a \equiv 2\left[\frac{(s_2 - s_3)t_1 + (s_3 - s_1)t_2 + (s_1 - s_2)t_3}{(t_1 - t_2)(t_2 - t_3)(t_3 - t_1)}\right] \quad (8)$$

is a constant (Klamkin 1995, 1996).

Consider the measurement of acceleration in a rotating reference frame. Apply the ROTATION OPERATOR

$$\tilde{R} \equiv \left(\frac{d}{dt}\right)_{\text{body}} + \boldsymbol{\omega}\times \quad (9)$$

twice to the RADIUS VECTOR $\mathbf{r}$ and suppress the *body* notation,

$$\begin{aligned}\mathbf{a}_{\text{space}} = \tilde{R}^2\mathbf{r} = \left(\frac{d}{dt} + \boldsymbol{\omega}\times\right)^2 \\ \mathbf{r} &= \left(\frac{d}{dt} + \boldsymbol{\omega}\times\right)\left(\frac{d\mathbf{r}}{dt} + \boldsymbol{\omega}\times\mathbf{r}\right) \\ &= \frac{d^2\mathbf{r}}{dt^2} + \frac{d}{dt}(\boldsymbol{\omega}\times\mathbf{r}) + \boldsymbol{\omega}\times\frac{d\mathbf{r}}{dt} + \boldsymbol{\omega}\times(\boldsymbol{\omega}\times\mathbf{r}) \\ &= \frac{d^2\mathbf{r}}{dt^2} + \boldsymbol{\omega}\times\frac{d\mathbf{r}}{dt} + \mathbf{r}\times\frac{d\boldsymbol{\omega}}{dt} + \boldsymbol{\omega}\times\frac{d\mathbf{r}}{dt} \\ &\quad + \boldsymbol{\omega}\times(\boldsymbol{\omega}\times\mathbf{r}).\end{aligned} \quad (10)$$

Grouping terms and using the definitions of the VELOCITY $\mathbf{v} \equiv d\mathbf{r}/dt$ and ANGULAR VELOCITY $\boldsymbol{\alpha} \equiv d\boldsymbol{\omega}/dt$ give the expression

$$\mathbf{a}_{\text{space}} = \frac{d^2\mathbf{r}}{dt^2} + 2\omega \times \mathbf{v} + \omega \times (\omega \times \text{r}) + \text{r} \times \boldsymbol{\alpha}. \quad (11)$$

Now, we can identify the expression as consisting of three terms

$$\mathbf{a}_{\text{body}} \equiv \frac{d^2\mathbf{r}}{dt^2}, \quad (12)$$

$$\mathbf{a}_{\text{Coriolis}} \equiv 2\omega \times \mathbf{v}, \quad (13)$$

$$\mathbf{a}_{\text{centrifugal}} \equiv \omega \times (\omega \times \mathbf{r}), \quad (14)$$

a "body" acceleration, centrifugal acceleration, and Coriolis acceleration. Using these definitions finally gives

$$\mathbf{a}_{\text{space}} = \mathbf{a}_{\text{body}} + \mathbf{a}_{\text{Coriolis}} + \mathbf{a}_{\text{centrifugal}} + \mathbf{r} \times \boldsymbol{\alpha}, \quad (15)$$

where the fourth term will vanish in a uniformly rotating frame of reference (i.e., $\alpha = 0$). The centrifugal acceleration is familiar to riders of merry-go-rounds, and the Coriolis acceleration is responsible for the motions of hurricanes on Earth and necessitates large trajectory corrections for intercontinental ballistic missiles.

Amphichiral

Ackermann Function

The Ackermann function is the simplest example of a well defined total function which is computable but not primitive recursive, providing a counterexample to the belief in the early 1900s that every computable function was also primitive recursive (Dötzel 1991). It grows faster than an exponential function, or even a multiple exponential function. The Ackermann function $A(x,y)$ is defined by

$$A(x,\ y) \equiv \begin{cases} y+1 & \text{if } x=0 \\ A(x-1,\ 1) & \text{if } y=0 \\ A(x-1, A(x,\ y-1)) & \text{otherwise.} \end{cases} \quad (1)$$

Special values for integer x include

$$A(0,\ y) = y+1 \quad (2)$$

$$A(1,\ y) = y+2 \quad (3)$$

$$A(2,\ y) = 2y+3 \quad (4)$$

$$A(3,\ y) = 2^{y+3} - 3 \quad (5)$$

$$A(4,\ y) = \underbrace{2^{2^{\cdot^{\cdot^{2}}}}}_{y+3} - 3. \quad (6)$$

Expressions of the latter form are sometimes called power towers. $A(0,\ y)$ follows trivially from the definition. $A(1,\ y)$ can be derived as follows,

$$\begin{aligned} A(1,\ y) &= A(0,\ A(1,\ y-1)) = A(1,\ y-1)+1 \\ &= A(0,\ A(1, y-2)) + 1 = A(1, y-2) + 2 \\ &= \ldots = A(1,\ 0) + y = A(0,1) + y = y+2. \end{aligned} \quad (7)$$

$A(2,y)$ has a similar derivation,

$$\begin{aligned} A(2,\ y) &= A(1,\ A(2,\ y-1)) = A(2,\ y-1) + 2 \\ &= A(1,\ A(2,\ y-2)) + 2 = A(2,\ y-2) + 4 = \ldots \\ &= A(2,\ 0) + 2y = A(1,\ 1) + 2y = 2y+3. \end{aligned} \quad (8)$$

Buck (1963) defines a related function using the same fundamental recurrence relation (with arguments flipped from Buck's convention)

$$F(x,\ y) = F(x-1, F(x,\ y-1)), \quad (9)$$

but with the slightly different boundary values

$$F(0,\ y) = y+1 \quad (10)$$

$$F(1,\ 0) = 2 \quad (11)$$

$$F(2,\ 0) = 2 \quad (12)$$

$$F(x,\ 0) = 1 \quad \text{for } x = 3,\ 4, \ldots. \quad (13)$$

Buck's recurrence gives

$$F(1,\ y) = 2+y \quad (14)$$

$$F(2,\ y) = 2y \quad (15)$$

$$F(3,\ y) = 2^y \quad (16)$$

$$F(4, y) = \underbrace{2^{2^{\cdot^{\cdot^{2}}}}}_{y}. \quad (17)$$

Taking $F(4, n)$ gives the sequence 1, 2, 4, 16, 65536, 2^{65536}, ... (Sloane's A006263). Defining $ah(x) = F(x, x)$ for $x = 0$, 1, ... then gives 1, 3, 4, 8, 65536, $\underbrace{2^{2^{\cdot^{\cdot^{2}}}}}_{m}$, ... (Sloane's A001695), where $m = \underbrace{2^{\cdot^{\cdot^{2}}}}_{65536}$, a truly huge number!

Acnode

Another name for an ISOLATED POINT.

See also CRUNODE, SPINODE, TACNODE

Acoptic Polyhedron

A term invented by B. Grünbaum in an attempt to promote concrete and precise POLYHEDRON terminology. The word "coptic" derives from the Greek for "to cut," and acoptic polyhedra are defined as POLYHEDRA for which the FACES do not intersect (cut) themselves, making them 2-MANIFOLDS.

See also HONEYCOMB, NOLID, POLYHEDRON, SPONGE

Action

Let $M(X)$ denote the GROUP of all invertible MAPS $X \to X$ and let G be any GROUP. A HOMOMORPHISM $\theta : G \to M(X)$ is called an action of G on X. Therefore, θ satisfies

1. For each $g \in G$, $\theta(g)$ is a MAP $X \to X : x \mapsto \theta(g)x$,
2. $\theta(gh)x = \theta(g)(\theta(h)x)$,
3. $\theta(e)x = x$, where e is the group identity in G,
4. $\theta(g^{-1})x = \theta(g)^{-1}x$.

See also CASCADE, FLOW, SEMIDIRECT PRODUCT, SEMIFLOW

Actuarial Polynomial

The polynomials $a_n^{(\beta)}(x)$ given by the SHEFFER SEQUENCE with

$$g(t) = (1-t)^{-\beta} \quad (1)$$

$$f(t) = \ln(1-t), \quad (2)$$

giving GENERATING FUNCTION

$$\sum_{k=0}^{\infty} \frac{a_n^{(\beta)}}{k!} t^k = e^{x(1-e^t)+\beta t}. \quad (3)$$

The Sheffer identity is

$$a_n^{(\beta)}(x+y) = \sum_{k=0}^{n} \binom{n}{k} a_k^{(\beta)}(y)\phi_{n-k}(-x), \quad (4)$$

where $\phi_n(x)$ is an EXPONENTIAL POLYNOMIAL. The actuarial polynomials are given in terms of the EXPONENTIAL POLYNOMIALS $\phi_n(x)$ by

$$a_n^{(\beta)}(x) = (1-t)^{\beta}\phi_n(-x) \quad (5)$$

$$= \sum_{k=0}^{n} \binom{\beta}{k} \phi_n^{(k)}(-x). \quad (6)$$

They are related to the STIRLING NUMBERS OF THE SECOND KIND $S(n, m)$ by

$$a_n^{(\beta)}(x) = \sum_{k=0}^{n} \binom{\beta}{k} \sum_{j=k}^{n} S(n, j)(j)_k(-x)^{j-k}, \quad (7)$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT and $(x)_n$ is a FALLING FACTORIAL. The actuarial polynomials also satisfy the identity

$$a_n^{(\beta)}(-x) = e^{-x} \sum_{k=0}^{\infty} \frac{(k+\beta)^n}{k!} x^k \qquad (8)$$

(Roman 1984, p. 125; Whittaker and Watson 1990, p. 336).

The first few polynomials are

$$a_0^{(\beta)}(x) = 1$$

$$a_1^{(\beta)}(x) = -x + \beta$$

$$a_2^{(\beta)}(x) = x^2 - x(1+2\beta) + \beta^2$$

$$a_3^{(\beta)}(x) = -x^3 + 3x^2(\beta+1) - x(3\beta^2 + 3\beta + 1) + \beta^3.$$

Acute Angle

An ANGLE of less than $\pi/2$ RADIANS (90°) is called an acute angle.

See also ACUTE TRIANGLE, ANGLE, FULL ANGLE, OBTUSE ANGLE, REFLEX ANGLE, RIGHT ANGLE, STRAIGHT ANGLE

Acute Triangle

A TRIANGLE in which all three ANGLES are ACUTE ANGLES. A TRIANGLE which is neither acute nor a RIGHT TRIANGLE (i.e., it has an OBTUSE ANGLE) is called an OBTUSE TRIANGLE. From the LAW OF COSINES, for a triangle with side lengths a, b, and c,

$$\cos C = \frac{a^2 + b^2 - c^2}{2ab},$$

with C the angle opposite side C. For an angle to be acute, $\cos C > 0$. Therefore, an acute triangle satisfies $a^2 + b^2 > c^2$, $b^2 + c^2 > a^2$, and $c^2 + a^2 > b^2$.

The smallest number of acute triangles into which an arbitrary OBTUSE TRIANGLE can be dissected is seven if $B > 90°$, $B - A$, $B - C < 90°$, and otherwise eight (Manheimer 1960, Gardner 1981, Wells 1991). A SQUARE can be dissected into as few as 9 acute triangles (Gardner 1981, Wells 1991).

Acyclic Digraph

An acyclic digraph is a DIRECTED GRAPH containing no directed cycles, also known as a directed acyclic graph or a "DAG." Every acyclic digraph has at least one node of OUTDEGREE 0. The numbers of acyclic digraphs on $n = 1, 2, \ldots$ vertices are 1, 2, 6, 31, 302, 5984, ... (Sloane's A003087).

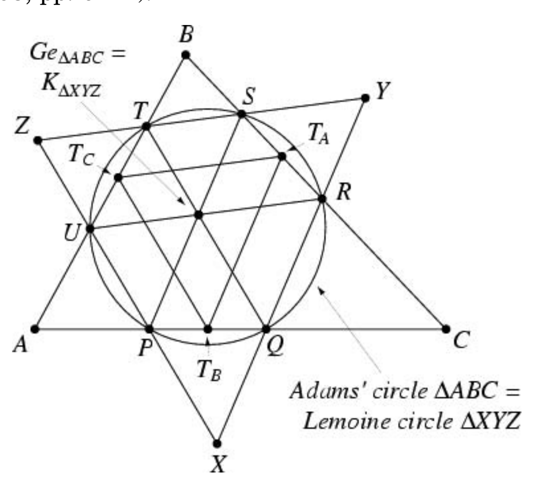
FOREST



Ad

ADJOINT REPRESENTATION, ADJOINT REPRESENTATION (LIE GROUP)

Adams' Circle

Given a TRIANGLE ΔABC, construct the CONTACT TRIANGLE $\Delta T_A T_B T_C$. Now extend lines parallel to the sides of the CONTACT TRIANGLE from the GERGONNE POINT. These intersect the triangle ΔABC in the six points P, Q, R, S, T, and U. As C. Adams proved in 1843, these points are CONCYCLIC in a CIRCLE now known as Adams' circle. Moreover, Adams' circle is concentric with the INCIRCLE of ΔABC (Honsberger 1995, pp. 62–4).

Extend the segments UP, TS, and RQ to form a TRIANGLE ΔXYZ. Then the GERGONNE POINT of ΔABC is the SYMMEDIAN POINT of ΔXYZ, and Adams' circle of ΔABC is the LEMOINE CIRCLE of ΔXYZ (Honsberger 1995, p. 98).

See also CONTACT TRIANGLE, GERGONNE POINT

Adams' Method

Adams' method is a numerical METHOD for solving linear FIRST-ORDER ORDINARY DIFFERENTIAL EQUATIONS OF THE FORM

$$\frac{dy}{dx} = f(x, y). \tag{1}$$

Let

$$h = x_{n+1} - x_n \tag{2}$$

be the step interval, and consider the MACLAURIN SERIES of y about x_n,

$$y_{n+1} = y_n + \left(\frac{dy}{dx}\right)_n (x - x_n) + \frac{1}{2}\left(\frac{d^2y}{dx^2}\right)_n (x - x_n)^2 + \ldots \tag{3}$$

$$\left(\frac{dy}{dx}\right)_{n+1} = \left(\frac{dy}{dx}\right)_n + \left(\frac{d^2y}{dx^2}\right)_n (x - x_n)^2 + \ldots. \tag{4}$$

Here, the DERIVATIVES of y are given by the BACKWARD DIFFERENCES

$$q_n \equiv \left(\frac{dy}{dx}\right)_n = \frac{\Delta y_n}{x_{n+1} - x_n} = \frac{y_{n+1} - y_n}{h} \tag{5}$$

$$\nabla q_n \equiv \left(\frac{d^2y}{dx^2}\right)_n = q_n - q_{n-1} \tag{6}$$

$$\nabla^2 q_n \equiv \left(\frac{d^3y}{dx^3}\right)_n = \nabla q_n - \nabla q_{n-1}, \tag{7}$$

etc. Note that by (1), q_n is just the value of $f(x_n, y_n)$.

For first-order interpolation, the method proceeds by iterating the expression

$$y_{n+1} = y_n + q_n h \tag{8}$$

where $q_n \equiv f(x_n, y_n)$. The method can then be extended to arbitrary order using the finite difference integration formula from Beyer (1987)

$$\int_0^1 f_p\,dp = \left(1 + \tfrac{1}{2}\nabla + \tfrac{5}{12}\nabla^2 + \tfrac{3}{8}\nabla^3 + \tfrac{251}{720}\nabla^4 + \tfrac{95}{288}\nabla^5 + \tfrac{19087}{60480}\nabla^6 + \ldots\right) f_p \tag{9}$$

to obtain

$$y_{n+1}-y_n=h(q_n+\tfrac{1}{2}\nabla q_{n-1}+\tfrac{5}{12}\nabla^2 q_{n-2}+\tfrac{3}{8}\nabla^3 q_{n-3} +\tfrac{251}{720}\nabla^4 q_{n-4}+\tfrac{95}{288}\nabla^5 q_{n-5}+\ldots). \quad (10)$$

Note that von Kármán and Biot (1940) confusingly use the symbol normally used for FORWARD DIFFERENCES δ to denote BACKWARD DIFFERENCES ∇.

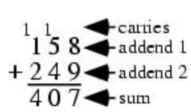
Adams-Bashforth-Moulton Method



ADAMS' METHOD

Addend

A quantity to be ADDED to another, also called a SUMMAND. For example, in the expression $a+b+c$, a, b, and c are all addends. The first of several addends, or "the one to which the others are added" (a in the previous example), is sometimes called the AUGEND.

See also ADDITION, AUGEND, PLUS, RADICAND

Addition

The combining of two or more quantities using the PLUS operator. The individual numbers being combined are called ADDENDS, and the total is called the SUM. The first of several ADDENDS, or "the one to which the others are added," is sometimes called the AUGEND. The opposite of addition is SUBTRACTION.

While the usual form of adding two n-digit INTEGERS (which consists of summing over the columns right to left and "CARRYING" a 1 to the next column if the sum exceeds 9) requires n operations (plus carries), two n-digit INTEGERS can be added in about 2 lg n steps by n processors using carry-lookahead addition (McGeoch 1993). Here, lg x is the LG function, the LOGARITHM to the base 2.

Addition Chain

An addition chain for a number n is a SEQUENCE $1=a_0<a_1<\ldots<a_r=n$, such that each member after a_0 is the SUM of two earlier (not necessarily distinct) ones. The number r is called the length of the addition chain. For example,

$$1,\ 1+1=2,\ 2+2=4,\ 4+2=6,\ 6+2=8,\ 8+6=14$$

is an addition chain for 14 of length $r=5$ (Guy 1994).

Additive Number Theory

The portion of NUMBER THEORY concerned with expressing an integer as a sum of integers from some given set.

See also CIRCLE METHOD, MULTIPLICATIVE NUMBER THEORY, NUMBER THEORY

Additive Persistence

Consider the process of taking a number, adding its DIGITS, then adding the DIGITS of the number derived from it, etc., until the remaining number has only one DIGIT. The number of additions required to obtain a single DIGIT from a number n is called the additive persistence of n, and the DIGIT obtained is called the DIGITAL ROOT of n.

For example, the sequence obtained from the starting number 9876 is (9876, 30, 3), so 9876 has an additive persistence of 2 and a DIGITAL ROOT of 3. The additive persistences of the first few positive integers are 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 1, 1, 1, 1, 1, 1, 1, 1, 2, 1, ... (Sloane's A031286). The smallest numbers of additive persistence n for $n = 0$, 1, ... are 0, 10, 19, 199, 19999999999999999999999, ... (Sloane's A006050).

Adéle

An element of an ADÉLE GROUP, sometimes called a REPARTITION in older literature (e.g., Chevalley 1951, p. 25). Adéles arise in both NUMBER FIELDS and FUNCTION FIELDS. The adéles of a NUMBER FIELD are the additive SUBGROUPS of all elements in $\prod k_v$, where v is the PLACE, whose ABSOLUTE VALUE is < 1 at all but finitely many vs.

Let F be a FUNCTION FIELD of algebraic functions of one variable. Then a MAP r which assigns to every PLACE P of F an element $r(P)$ of F such that there are only a finite number of PLACES P for which $vp(r(P)) < 0$ is called an adéle (Chevalley 1951, p. 1951).

See also FUNCTION FIELD, IDELE

Chevalley, C. C. *Introduction to the Theory of Algebraic Functions of One Variable.* Providence, RI: Amer. Math. Soc., p. 25, 1951.

Knapp, A. W. "Group Representations and Harmonic Analysis, Part II." *Not. Amer. Math. Soc.* **43**, 537–49, 1996.

Adéle Group

The restricted topological GROUP DIRECT PRODUCT of the GROUP G_{k_v} with distinct invariant open subgroups G_{0_v}.

References

Weil, A. *Adéles and Algebraic Groups.* Princeton, NJ: Princeton University Press, 1961.

Adem Relations

Relations in the definition of a STEENROD ALGEBRA which state that, for $i < 2j$,

$$Sq^i \circ Sq^j(x) = \sum_{k=0}^{\lfloor i \rfloor} \binom{j-k-1}{i-2k} Sq^{i+j-k} \circ Sq^k(x),$$

where $f \circ g$ denotes function COMPOSITION and $\lfloor i \rfloor$ is the FLOOR FUNCTION.

See also STEENROD ALGEBRA

Adequate Knot

A class of KNOTS containing the class of ALTERNATING KNOTS. Let $c(K)$ be the CROSSING NUMBER. Then for KNOT SUM $K_1 \# K_2$ which is an adequate knot,

$$c(K_1 \# K_2) = c(K_1) + c(K_2).$$

This relationship is postulated to hold true for all KNOTS.

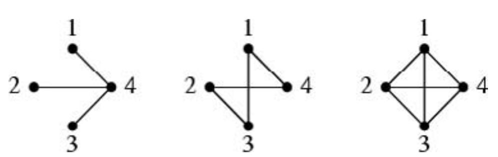
See also ALTERNATING KNOT, CROSSING NUMBER (LINK)

Adiabatic Invariant

A property of motion which is conserved to exponential accuracy in the small parameter representing the typical rate of change of the gross properties of the body.

See also ALGEBRAIC INVARIANT, LYAPUNOV CHARACTERISTIC NUMBER

Adjacency List



The adjacency list representation of a GRAPH consists of n lists one for each vertex v_i, $1 \le i \le n$, which gives the vertices to which v_i is adjacent. The adjacency lists of a graph g may be computed using `ToAdjacencyLists[g]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``). A graph may be constructed from adjacency lists using `FromAdjacencyLists[e]`.

See also ADJACENCY MATRIX

References

Skiena, S. "Adjacency Lists." §3.1.2 in *Implementing Discrete Mathematics: Combinatorics and Graph Theory with Mathematica.* Reading, MA: Addison-Wesley, pp. 86–7, 1990.

Adjacency Matrix

$$\begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 \\ 1 & 1 & 1 & 0 \end{pmatrix} \quad \begin{pmatrix} 0 & 0 & 1 & 1 \\ 0 & 0 & 1 & 1 \\ 1 & 1 & 0 & 0 \\ 1 & 1 & 0 & 0 \end{pmatrix} \quad \begin{pmatrix} 0 & 1 & 1 & 1 \\ 1 & 0 & 1 & 1 \\ 1 & 1 & 0 & 1 \\ 1 & 1 & 1 & 0 \end{pmatrix}$$

The adjacency matrix of a simple GRAPH is a MATRIX with rows and columns labeled by VERTICES, with a 1 or 0 in position (v_i, v_j) according to whether v_i and v_j are ADJACENT or not. For a simple graph with no self-loops, the adjacency matrix must have 0s on the diagonal. For an undirected graph, the adjacency matrix is symmetrical. The adjacency matrix of a graph can be computed using `Edges[g]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).

See also ADJACENCY LIST, INCIDENCE MATRIX, INTEGER MATRIX

References

Chartrand, G. *Introductory Graph Theory.* New York: Dover, p. 218, 1985.
Skiena, S. "Adjacency Matrices." §3.1.1 in *Implementing Discrete Mathematics: Combinatorics and Graph Theory with Mathematica.* Reading, MA: Addison-Wesley, pp. 81–5, 1990.

Adjacency Relation

The SET E of EDGES of a GRAPH (V, E), being a set of unordered pairs of elements of V, constitutes a RELATION on V. Formally, an adjacency relation is any RELATION which is IRREFLEXIVE and SYMMETRIC.

See also IRREFLEXIVE, RELATION, SYMMETRIC

Adjacent Fraction

Two FRACTIONS are said to be adjacent if their difference has a unit NUMERATOR. For example, 1/3 and 1/4 are adjacent since $1/3 - 1/4 = 1/12$, but 1/2 and 1/5 are not since $1/2 - 1/5 = 3/10$. Adjacent fractions can be adjacent in a FAREY SEQUENCE.

See also FAREY SEQUENCE, FORD CIRCLE, FRACTION, NUMERATOR

References

Pickover, C. A. *Keys to Infinity.* New York: Wiley, p. 119, 1995.

Adjacent Value

The value nearest to but still inside an inner FENCE.

References

Tukey, J. W. *Explanatory Data Analysis.* Reading, MA: Addison-Wesley, p. 667, 1977.

Adjacent Vertices

In a GRAPH G, two VERTICES are adjacent if they are joined by an EDGE.

See also EDGE (GRAPH), GRAPH, VERTEX (GRAPH)

Adjoint

Given a SECOND-ORDER ORDINARY DIFFERENTIAL EQUATION

$$\tilde{\mathscr{L}} u(x) \equiv p_0 \frac{d^2u}{dx^2} + p_1 \frac{du}{dx} + p_2 u, \tag{1}$$

where $p_i \equiv p_i(x)$ and $u \equiv u(x)$, the adjoint operator $\tilde{\mathscr{L}}^*$ is defined by

$$\begin{aligned} \tilde{\mathscr{L}}^* u &\equiv \frac{d}{dx^2}(p_0 u) - \frac{d}{dx}(p_1 u) + p_2 u \\ &= p_0 \frac{d^2u}{dx^2} + (2p_0' - p_1)\frac{du}{dx} + (p_0'' - p_1' + p_2)u. \end{aligned} \tag{2}$$

Write the two LINEARLY INDEPENDENT solutions as $y_1(x)$ and $y_2(x)$. Then the adjoint operator can also be

written

$$\tilde{\mathscr{L}}^{*}u = \int (y_2 \tilde{\mathscr{L}} y_1 - y_1 \tilde{\mathscr{L}} y_2) dx = \left[\frac{p_1}{p_0} (y_2' y_2 - y_1 y_2') \right]. \quad (3)$$

In general, given two adjoint operators $\tilde{A}$ and $\tilde{B}$,

$$(\tilde{A}\tilde{B})^* = \tilde{B}^* \tilde{A}^*, \quad (4)$$

which can be generalized to

$$(\tilde{A}\tilde{B} \cdots \tilde{Z})^* = \tilde{Z}^* \cdots \tilde{B}^* \tilde{A}^*. \quad (5)$$

Note that many older physics text use the a DAGGER notation $A^\dagger$ to denote the adjoint (Arfken 1985). For example, (Dirac 1982, p. 26) denotes the adjoint of the BRA vector $\langle P|\alpha$ as $\alpha^\dagger|P\rangle$, or $\bar{\alpha}|P\rangle$. The term Hermitian conjugate is sometimes also used instead of adjoint (Griffiths 1987, p. 22)

See also ADJOINT CURVE, ADJOINT MATRIX, DAGGER, HERMITIAN OPERATOR, SELF-ADJOINT, STURM-LIOUVILLE THEORY

Adjoint Curve

A curve which has at least multiplicity $r_i - 1$ at each point where a given curve (having only ordinary singular points and cusps) has a multiplicity r_i is called the adjoint to the given curve. When the adjoint curve is of order $n-3$, it is called a special adjoint curve.

References

Coolidge, J. L. *A Treatise on Algebraic Plane Curves.* New York: Dover, p. 30, 1959.

Adjoint Matrix

The adjoint matrix, sometimes also called the adjugate matrix or conjugate transpose (Golub and van Loan 1996, p. 14), of an $m \times n$ MATRIX A is the $n \times m$ matrix defined by

$$\mathsf{A}^* \equiv \bar{\mathsf{A}}^{\mathrm{T}}, \quad (1)$$

where the ADJOINT operator is denoted with a star, T denotes the TRANSPOSE, and $\bar{\mathsf{A}}$ denotes the CONJUGATE MATRIX. Unfortunately, several different notations are in use. Older physics text commonly use $\mathsf{A}^\dagger$ (Arfken 1985, p. 210), mathematicians commonly use A^* (Courant and Hilbert 1989, p. 9), and computer scientists sometimes use A^{H} (Golub and van Loan 1996, p. 14). In this work, a star is used to denote the adjoint operator, so care must be taken not to confuse this with the star used in older physics and engineering texts to denote the COMPLEX CONJUGATE.

If a MATRIX is SELF-ADJOINT, it is said to be HERMITIAN. The adjoint matrix of a MATRIX product is given by

$$(ab)^*_{ij} \equiv \overline{[(ab)^{\mathrm{T}}]}_{ij}. \quad (2)$$

Using the identity for the product of TRANSPOSE gives

$$\overline{[(ab)^{\mathrm{T}}]}_{ij} = \overline{[b^{\mathrm{T}}a^{\mathrm{T}}]}_{ij} = \overline{b^{\mathrm{T}}_{ik}a^{\mathrm{T}}_{kj}} = \overline{[b^{\mathrm{T}}]}_{ik}\overline{[a^{\mathrm{T}}]}_{kj} = b^*_{ik}a^*_{kj}$$
$$= [b^*a^*]_{ij}, \quad (3)$$

where EINSTEIN SUMMATION has been used here to sum over repeated indices, it follows that

$$(\mathsf{AB})^* = \mathsf{B}^*\mathsf{A}^*. \quad (4)$$

Adjoint Operator

Given a SECOND-ORDER ORDINARY DIFFERENTIAL EQUATION

$$p_i \equiv p_i(x) \quad (1)$$

where $u \equiv u(x)$ and $\tilde{\mathscr{L}}^*$, the adjoint operator $\tilde{\mathscr{L}}^*$u (denoted by a DAGGER), is defined by

$$\frac{d}{dx^2}(p_0 u) - \frac{d}{dx}(p_1 u) + p_2 u(y_1 y_2'' - y_2 y_1'') + P(y_1 y_2' - y_1' y_2)$$
$$+Q(y_1 y_2 - y_1 y_2) = 0^{p0}$$

$$p_0 \frac{d^2u}{dx^2} + (2p_0' - p_1)\frac{du}{dx} + (p_0'' - p_1' + p_2)u = \tilde{\mathscr{L}}^* u$$
$$= \int (y_2 \tilde{\mathscr{L}} y_1 - y_1 \tilde{\mathscr{L}} y_2)\, dx = \left[\frac{p_1}{p_0}(y_1' y_2 - y_1 y_2')\right]. \quad (2)$$

Write the two LINEARLY INDEPENDENT solutions as $y' = f_0(x) + f_1(x)y + f_0(x)y^2 + f_3(x)y^3 + \ldots$ and $[g_0(x) + g_1(x)y]y' = f_0(x) + f_1(x)y + f_2(x)y^2 + f_3(x)y^3$. Then the adjoint operator can also be written

$$\tilde{A}. \quad (3)$$

In general, given two adjoint operators $\tilde{B}$ and $(\tilde{A}\tilde{B})^* = \tilde{B}^*\tilde{A}^*$,

$$(\tilde{A}\tilde{B}\cdots\tilde{Z})^* = \tilde{Z}^*\cdots\tilde{B}^*\tilde{A}^*. \tag{4}$$

which can be generalized to

$$A^{\dagger}. \tag{5}$$

The adjoint of the BRA vector $\langle P|\alpha$ is denoted $\alpha^\dagger|P\rangle$, or $\bar{\alpha}|P\rangle$ (Dirac 1982, p. 26). The term Hermitian conjugate is sometimes also used (Griffiths 1987, p. 22)

Adjoint Representation

A LIE ALGEBRA is a VECTOR SPACE g with a LIE BRACKET $[X, Y]$, satisfying the JACOBI IDENTITY. Hence any element X gives a linear transformation given by

$$\operatorname{ad}(X)(Y) = [X, Y], \tag{1}$$

which is called the adjoint representation of g. It is a LIE ALGEBRA REPRESENTATION because of the JACOBI IDENTITY,

$$[\operatorname{ad}(X_1), \operatorname{ad}(X_2)](Y) = [X_1, [X_2, Y]] - [X_2, [X_1, Y]]$$

$$= [[X_1, X_2], Y] = \operatorname{ad}([X_1, X_2])(Y). \tag{2}$$

A REPRESENTATION is given by matrices. The simplest LIE ALGEBRA is gl_n the set of matrices. Consider the adjoint representation of gl_2, which has four dimensions and so will be a four dimensional representation. The matrices

$$e_1 = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} \tag{3}$$

$$e_2 = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \tag{4}$$

$$e_3 = \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix} \tag{5}$$

$$e_4 = \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix} \tag{6}$$

give a basis for gl_2. Using this basis, the adjoint representation is described by the following matrices,

$$\operatorname{ad} e_1 = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix} \tag{7}$$

$$\operatorname{ad} e_2 = \begin{bmatrix} 0 & 0 & 1 & 0 \\ -1 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & -1 & 0 \end{bmatrix} \tag{8}$$

$$\operatorname{ad} e_3 = \begin{bmatrix} 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & -1 \\ 0 & 1 & 0 & 0 \end{bmatrix} \tag{9}$$

$$\operatorname{ad} e_4 = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}. \tag{10}$$

The following *Mathematica* function gives the adjoint representation of the matrix m in the Lie algebra, given by a basis, the list of matrices g.

```
ad[g_List, m_List?MatrixQ]:= Transpose[Li-
nearSolve[Transpose[Flatten/@g],
   Flatten[m.#1-#1.m]]&/@g]
```

Adjugate Matrix

ADJOINT MATRIX

Adjunction

If a is an element of a FIELD F over the PRIME FIELD P, then the set of all RATIONAL FUNCTIONS of a with COEFFICIENTS in P is a FIELD derived from P by adjunction of a.

Adleman-Pomerance-Rumely Primality Test

A modified MILLER'S PRIMALITY TEST which gives a guarantee of PRIMALITY or COMPOSITENESS. The ALGORITHM's running time for a number n has been proved to be as $\mathcal{O}((\ln n)^{c \ln \ln \ln n})$ for some $c > 0$. It was simplified by Cohen and Lenstra (1984), implemented by Cohen and Lenstra (1987), and subsequently optimized by Bosma and van der Hulst (1990).

Adleman-Rumely Primality Test

ADLEMAN-POMERANCE-RUMELY PRIMALITY TEST

Admissible

A string or word is said to be admissible if that word appears in a given SEQUENCE. For example, in the SEQUENCE $aabaabaabaabaab\ldots$, a, aa, $baab$ are all admissible, but bb is inadmissible.

See also BLOCK GROWTH

Ado's Theorem

Every finite-dimensional LIE ALGEBRA of characteristic $p = 0$ has a FAITHFUL finite-dimensional representation.

Affine Complex Plane

The set $\mathbb{A}^2$ of all ORDERED PAIRS of COMPLEX NUMBERS.

See also AFFINE CONNECTION, AFFINE EQUATION, AFFINE GEOMETRY, AFFINE GROUP, AFFINE HULL, AFFINE PLANE, AFFINE SPACE, AFFINE TRANSFORMATION, AFFINITY, COMPLEX PLANE, COMPLEX PROJECTIVE PLANE

Affine Connection

CONNECTION COEFFICIENT

Affine Equation

A nonhomogeneous LINEAR EQUATION or system of nonhomogeneous LINEAR EQUATIONS is said to be affine.

See also AFFINE COMPLEX PLANE, AFFINE CONNECTION, AFFINE GEOMETRY, AFFINE GROUP, AFFINE HULL, AFFINE PLANE, AFFINE SPACE, AFFINE TRANSFORMATION, AFFINITY

Affine Geometry

A GEOMETRY in which properties are preserved by PARALLEL PROJECTION from one PLANE to another. In an affine geometry, the third and fourth of EUCLID'S POSTULATES become meaningless. This type of GEOMETRY was first studied by Euler.

See also ABSOLUTE GEOMETRY, AFFINE COMPLEX PLANE, AFFINE CONNECTION, AFFINE EQUATION, AFFINE GROUP, AFFINE HULL, AFFINE PLANE, AFFINE SPACE, AFFINE TRANSFORMATION, AFFINITY, ORDERED GEOMETRY

Affine Hull

The IDEAL generated by a SET in a VECTOR SPACE.

See also AFFINE COMPLEX PLANE, AFFINE CONNECTION, AFFINE EQUATION, AFFINE GEOMETRY, AFFINE GROUP, AFFINE PLANE, AFFINE SPACE, AFFINE TRANSFORMATION, AFFINITY, CONVEX HULL, HULL

Affine Plane

A 2-D AFFINE GEOMETRY constructed over a FINITE FIELD. For a FIELD F of size n, the affine plane consists of the set of points which are ordered pairs of elements in F and a set of lines which are themselves a set of points. Adding a POINT AT INFINITY and LINE AT INFINITY allows a PROJECTIVE PLANE to be constructed from an affine plane. An affine plane of order n is a BLOCK DESIGN OF THE FORM $(n^2, n, 1)$. An affine plane of order n exists IFF a PROJECTIVE PLANE of order n exists.

Affine Scheme

Let P be the set of PRIME IDEALS of a COMMUTATIVE RING A. Then an affine scheme is a technical mathematical object defined as the SPECTRUM $\sigma(A)$ of P, regarded as a local-ringed space with a structure sheaf. A local-ringed space that is locally isomorphic to an affine scheme is called a SCHEME (Itô 1986, p. 69).

See also PRIME IDEAL, SCHEME, SPECTRUM (RING)

References

Itô, K. (Ed.). "Schemes." §16D in *Encyclopedic Dictionary of Mathematics, 2nd ed., Vol. 1.* Cambridge, MA: MIT Press, p. 69, 1986.

Affine Space

Let V be a VECTOR SPACE over a FIELD K, and let A be a nonempty SET. Now define addition $p+\mathbf{a}\in A$ for any VECTOR $\mathbf{a}\in V$ and element $p\in A$ subject to the conditions

1. $p+\mathbf{0}=p$,
2. $(p+\mathbf{a})+\mathbf{b}=p+(\mathbf{a}+\mathbf{b})$,
3. For any $q\in A$, there EXISTS a unique VECTOR $\mathbf{a}\in V$ such that $q=p+\mathbf{a}$.

Here, $\mathbf{a}$, $\mathbf{b}\in V$. Note that (1) is implied by (2) and (3). Then A is an affine space and K is called the COEFFICIENT FIELD.

In an affine space, it is possible to fix a point and coordinate axis such that every point in the SPACE can be REPRESENTED AS an n-tuple of its coordinates. Every ordered pair of points A and B in an affine space is then associated with a VECTOR AB.

See also AFFINE COMPLEX PLANE, AFFINE CONNECTION, AFFINE EQUATION, AFFINE GEOMETRY, AFFINE GROUP, AFFINE HULL, AFFINE PLANE, AFFINE SPACE, AFFINE TRANSFORMATION, AFFINITY

Affine Transformation

Any TRANSFORMATION preserving COLLINEARITY (i.e., all points lying on a LINE initially still lie on a LINE after TRANSFORMATION) and ratios of distances (e.g., the midpoint of a line segment remains the midpoint after transformation). An affine transformation may also be thought of as a shearing transformation (Croft *et al.* 1991). An affine transformation is also called an AFFINITY.

An affine transformation of $\mathbb{R}^n$ is a MAP $F:\mathbb{R}^n\to\mathbb{R}^n$ OF THE FORM

$$F(\mathrm{p}) = A\mathbf{p}+\mathbf{q} \tag{1}$$

for all $p\in\mathbb{R}^n$, where A is a linear transformation of $\mathbb{R}^n$. If $\det(A)=1$, the transformation is ORIENTATION-PRESERVING; if $\det(A)=-1$, it is ORIENTATION-REVERSING.

CONTRACTION, EXPANSION, DILATION, REFLECTION, SIMILARITY TRANSFORMATIONS, SPIRAL SIMILARITIES, ROTATION, and TRANSLATION are all affine transformations, as are their combinations. A particular example combining ROTATION and EXPANSION is the rotation-enlargement transformation

$$\begin{aligned}\begin{bmatrix}x'\\ y'\end{bmatrix} &= s\begin{bmatrix}\cos\alpha & \sin\alpha\\ -\sin\alpha & \cos\alpha\end{bmatrix}\begin{bmatrix}x-x_0\\ y-y_0\end{bmatrix}\\ &= s\begin{bmatrix}\cos\alpha(x-x_0)+\sin\alpha(y-y_0)\\ -\sin\alpha(x-x_0)+\cos\alpha(y-y_0)\end{bmatrix}.\end{aligned} \tag{2}$$

Separating the equations,

$$x' = (s\cos\alpha)x+(s\sin\alpha)y-s(x_0\cos\alpha+y_0\sin\alpha) \tag{3}$$

$$y' = (-s\sin\alpha)x+(s\cos\alpha)y+s(x_0\sin\alpha-y_0\cos\alpha). \tag{4}$$

This can be also written as

$$x' = ax+by+c \tag{5}$$

$$y' = bx+ay+d, \tag{6}$$

where

$$a = s\cos\alpha \tag{7}$$

$$b = -s\sin\alpha. \tag{8}$$

The scale factor s is then defined by

$$s \equiv \sqrt{a^2+b^2}, \tag{9}$$

and the rotation ANGLE by

$$\alpha = \tan^{-1}\left(-\frac{b}{a}\right). \tag{10}$$

Affine Variety

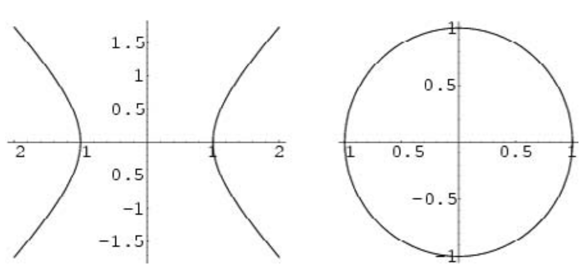
An affine variety V is a VARIETY contained in AFFINE SPACE. For example,

$$\{(x, y, z) : x^2 + y^2 - z^2 = 0\} \qquad (1)$$

is the CONE, and

$$\{(x, y, z) : x^2 + y^2 - z^2 = 0, \ ax + by + cz = 0\} \qquad (2)$$

is a CONIC SECTION, which is a SUBVARIETY of the cone. The cone can be written $V(x^2 + y^2 - z^2)$ to indicate that it is the variety corresponding to $x^2 + y^2 - z^2 = 0$. Naturally, many other polynomials vanish on $V(x^2 + y^2 - z^2)$, in fact all polynomials in $I(C) = \{x^2 + y^2 - z^2\}$. The set $I(C)$ is an IDEAL in the POLYNOMIAL RING $\mathbb{C}[x, y, z]$. Note also, that the ideal of polynomials vanishing on the conic section is the IDEAL generated by $x^2 + y^2 - z^2$ and $ax + by + cz$.



A MORPHISM between two affine varieties is given by polynomial coordinate functions. For example, the map $\phi(x, y, z) = (x^2, y^2, z^2)$ is a MORPHISM from $X = V(x^2 + y^2 + z^2)$ to $Y = V(x + y + z)$. Two affine varieties are ISOMORPHIC if there is a MORPHISM which has an inverse morphism. For example, the affine variety $V(x^2 + y^2 + z^2)$ is isomorphic to the cone $V(x^2 + y^2 - z^2)$ via the coordinate change $\phi(x, y, z) = (x, y, iz)$.

Many polynomials f may be factored, for instance $f = x^2 + y^2 = (x + iy)(x - iy)$, and then $V(f) = V(x + iy) \cup V(x - iy)$. Consequently, only IRREDUCIBLE POLYNOMIALS, and more generally only PRIME IDEALS p are used in the definition of a variety. An affine variety V is the set of common zeros of a collection of polynomials $p_1, ..., p_k$, i.e.,

$$V = \{x = (x_1, \ldots, x_n) : p_1(x) = \ldots = p_k(x) = 0\} \qquad (3)$$

as long as the IDEAL $I = (p_1, \ldots, p_k)$ is a PRIME IDEAL. More classically, an affine variety is defined by any set of polynomials, i.e., what is now called an ALGEBRAIC SET. Most points in V will have dimension $n - k$, but V may have singular points like the origin in the cone.

When V is one-dimensional generically (at almost all points), which typically occurs when $k = n - 1$, then V is called a curve. When V is two-dimensional, it is called a surface. In the case of COMPLEX affine space, a curve is a RIEMANN SURFACE, possibly with some singularities.

Mathematica has a built-in function `ImplicitPlot` in the *Mathematica* add-on package ``Graphics`ImplicitPlot` `` (which can be loaded with the command ``<<Graphics` ``) that will graph affine varieties in the real affine plane. For example, the following graphs a hyperbola and a circle.

```
<<Graphics`;
 Show[GraphicsArray[{
   ImplicitPlot[x^2 - y^2 == 1, {x, -2, 2},
DisplayFunction -> Identity],
   ImplicitPlot[x^2 + y^2 == 1, {x, -2, 2},
DisplayFunction -> Identity]
  }]]
```

An extension to this function called `ImplicitPlot3D` can be downloaded from MathSource and used to plot affine varieties in three-dimensional space.

Ahlfors Five Island Theorem

Let $f(z)$ be a TRANSCENDENTAL MEROMORPHIC FUNCTION, and let $D_1, D_2, ..., D_5$ be five SIMPLY CONNECTED domains in $\mathbb{C}$ with disjoint closures (Ahlfors 1932). Then there exists $j \in \{1, 2, \ldots, 5\}$ and, for any $R > 0$, a SIMPLY CONNECTED domain $G \subset \{z \in \mathbb{C} : |z| > R\}$ such that $f(z)$ is a CONFORMAL MAP of G onto D_j. If $f(z)$ has only finitely many POLES, then "five" may be replaced by "three" (Ahlfors 1933).

See also MEROMORPHIC FUNCTION, TRANSCENDENTAL FUNCTION

Ahlfors-Bers Theorem

The RIEMANN'S MODULI SPACE gives the solution to RIEMANN'S MODULI PROBLEM, which requires an ANALYTIC parameterization of the compact RIEMANN SURFACES in a fixed HOMEOMORPHISM.

A-Integrable

A generalization of the LEBESGUE INTEGRAL. A MEASURABLE FUNCTION $f(x)$ is called A-integrable over the CLOSED INTERVAL $[a, b]$ if

$$m\{x : |f(x)| > n\} = \mathcal{O}(n^{-1}), \tag{1}$$

where m is the LEBESGUE MEASURE, and

$$I = \lim_{n\to\infty} \int_a^b [f(x)]_n \, dx \tag{2}$$

exists, where

$$[f(x)]_n = \begin{cases} f(x) & \text{if } |f(x)| \leq n \\ 0 & \text{if } |f(x)| > n. \end{cases} \tag{3}$$

Airy Differential Equation

Some authors define a general Airy differential equation as

$$y'' \pm k^2 xy = 0. \tag{1}$$

This equation can be solved by series solution using the expansions

$$y = \sum_{n=0}^{\infty} a_n x^n \tag{2}$$

$$y' = \sum_{n=0}^{\infty} n a_n x^{n-1} = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$= \sum_{n=0}^{\infty} (n+1) a_{n+1} x^n \tag{3}$$

$$y^n = \sum_{n=0}^{\infty} (n+1) n a_{n+1} x^{n-1} = \sum_{n=1}^{\infty} (n+1) n a_{n+1} x^{n-1}$$
$$= \sum_{n=0}^{\infty} (n+2)(n+1) a_{n+2} x^n. \tag{4}$$

Specializing to the "conventional" Airy differential equation occurs by taking the MINUS SIGN and setting $k^2 = 1$. Then plug (4) into

$$y'' - xy = 0 \tag{5}$$

to obtain

$$\sum_{n=0}^{\infty} (n+2)(n+1) a_{n+2} x^n - x \sum_{n=0}^{\infty} a_n x^n = 0 \tag{6}$$

$$\sum_{n=0}^{\infty} (n+2)(n+1) a_{n+2} x^n - \sum_{n=0}^{\infty} a_n x^{n+1} = 0 \tag{7}$$

$$2a_2 + \sum_{n=1}^{\infty} (n+2)(n+1) a_{n+2} x^n - \sum_{n=1}^{\infty} a_{n-1} x^n = 0 \tag{8}$$

$$2a_2 + \sum_{n=1}^{\infty} [(n+2)(n+1) a_{n+2} - a_{n-1}] x^n = 0. \tag{9}$$

In order for this equality to hold for all x, each term must separately be 0. Therefore,

$$a_2 = 0 \tag{10}$$

$$(n+2)(n+1) a_{n+2} = a_{n-1}. \tag{11}$$

Starting with the $n = 3$ term and using the above RECURRENCE RELATION, we obtain

$$5 \cdot 4 a_5 = 20 a_5 = a_2 = 0. \tag{12}$$

Continuing, it follows by INDUCTION that

$$a_2 = a_5 = a_8 = a_{11} = \ldots a_{3n-1} = 0 \tag{13}$$

for $n = 1, 2, ...$ Now examine terms OF THE FORM a_{3n}.

$$a_3 = \frac{a_0}{3 \cdot 2} \tag{14}$$

$$a_6 = \frac{a_3}{6 \cdot 5} = \frac{a_0}{(6 \cdot 5)(3 \cdot 2)} \quad (15)$$

$$a_9 = \frac{a_6}{9 \cdot 8} = \frac{a_0}{(9 \cdot 8)(6 \cdot 5)(3 \cdot 2)}. \quad (16)$$

Again by INDUCTION,

$$a_{3n} = \frac{a_0}{[(3n)(3n-1)][(3n-3)(3n-4)]\cdots[6 \cdot 5][3 \cdot 2]} \quad (17)$$

for $n = 1, 2, \ldots$. Finally, look at terms OF THE FORM a_{3n+1},

$$a_4 = \frac{a_1}{4 \cdot 3} \quad (18)$$

$$a_7 = \frac{a_4}{7 \cdot 6} = \frac{a_1}{(7 \cdot 6)(4 \cdot 3)} \quad (19)$$

$$a_{10} = \frac{a_7}{10 \cdot 9} = \frac{a_1}{(10 \cdot 9)(7 \cdot 6)(4 \cdot 3)}. \quad (20)$$

By INDUCTION,

$$a_{3n+1} = \frac{a_1}{[(3n+1)(3n)][(3n-2)(3n-3)]\cdots[7 \cdot 6][4 \cdot 3]} \quad (21)$$

for $n = 1, 2, \ldots$. The general solution is therefore

$$y = a_0\left[1 + \sum_{n=1}^{\infty} \frac{x^{3n}}{(3n)(3n-1)(3n-3)(3n-4)\cdots 3 \cdot 2}\right] + a_1\left[x + \sum_{n=1}^{\infty} \frac{x^{3n+1}}{(3n+1)(3n)(3n-2)(3n-3)\cdots 4 \cdot 3}\right]. \quad (22)$$

For a general k^2 with a MINUS SIGN, equation (1) is

$$y'' - k^2 xy = 0, \quad (23)$$

and the solution is

$$y(x) = \tfrac{1}{3}\sqrt{x}[AI_{-1/3}(\tfrac{2}{3}kx^{3/2}) - BI_{1/3}(\tfrac{2}{3}kx^{3/2})], \quad (24)$$

where I is a MODIFIED BESSEL FUNCTION OF THE FIRST KIND. This is usually expressed in terms of the AIRY FUNCTIONS $\mathrm{Ai}(x)$ and $\mathrm{Bi}(x)$

$$y(x) = A' \,\mathrm{Ai}(k^{2/3}x) + B'\mathrm{Bi}(k^{2/3}x). \quad (25)$$

If the PLUS SIGN is present instead, then

$$y'' + k^2 xy = 0 \quad (26)$$

and the solutions are

$$y(x) = \tfrac{1}{3}\sqrt{x}[AJ_{-1/3}(\tfrac{2}{3}kx^{3/2}) + BJ_{1/3}(\tfrac{2}{3}kx^{3/2})], \quad (27)$$

where $J(z)$ is a BESSEL FUNCTION OF THE FIRST KIND.

A generalization of the Airy differential equation is given by

$$y''' - 4xy' - 2y = 0, \quad (28)$$

which has solutions

$$y = C_1[\mathrm{Ai}(x)]^2 + C_2\mathrm{Ai}(x)\,\mathrm{Bi}(x) + C_3[\mathrm{Bi}(x)]^2 \quad (29)$$

(Abramowitz and Stegun 1972, p. 448; Zwillinger 1997, p. 128).

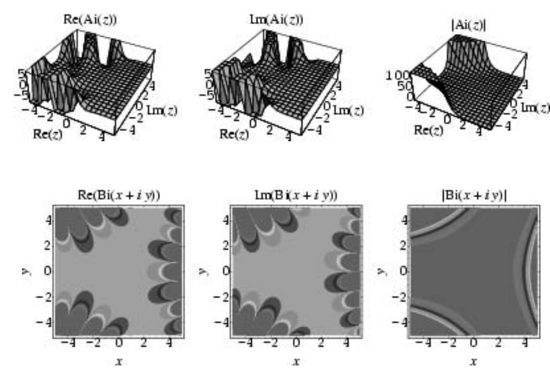
Airy Functions

The $\mathrm{Ai}(x)$ and $\mathrm{Bi}(x)$ functions are defined as the two LINEARLY INDEPENDENT solutions to

$$y'' - yz = 0. \quad (1)$$

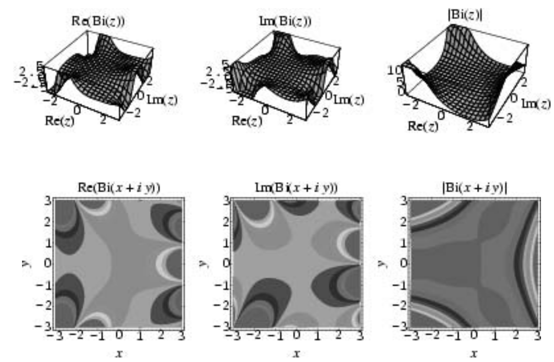
(Abramowitz and Stegun 1972, pp. 446–47; illustrated above), written in the form

$$y(z) = A\,\mathrm{Ai}(z) + B\,\mathrm{Bi}(z), \quad (2)$$



where

$$\mathrm{Ai}(z) = \tfrac{1}{3}\sqrt{x}\left[I_{-1/3}\left(\tfrac{2}{3}z^{3/2}\right) - I_{1/3}\left(\tfrac{2}{3}z^{3/2}\right)\right] = \sqrt{\frac{z}{3\pi}}K_{1/3}\left(\tfrac{2}{3}z^{3/2}\right) \quad (3)$$



$$\mathrm{Bi}(z) = \sqrt{\frac{z}{3}}\left[I_{-1/3}\left(\tfrac{2}{3}z^{3/2}\right) + I_{1/3}\left(\tfrac{2}{3}z^{3/2}\right)\right], \quad (4)$$

where $I(z)$ is a MODIFIED BESSEL FUNCTION OF THE FIRST KIND and $K(z)$ is a MODIFIED BESSEL FUNCTION OF THE SECOND KIND. The functions are implemented in *Mathematica* as `AiryAi[z]` and `AiryBi[z]`. Their derivatives are implemented as `AiryAiPrime[z]` and

`AiryBiPrime[z]`.

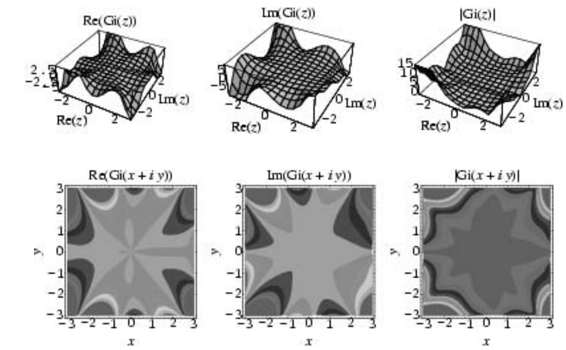
Plots of Ai(z) in the COMPLEX PLANE are illustrated above, and Bi(z) is illustrated below.

The Airy Ai(x) function is given by the integral

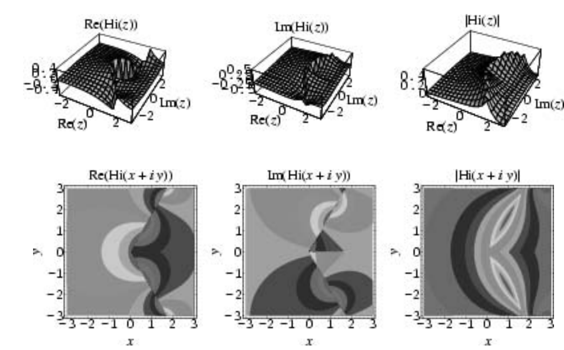
$$\mathrm{Ai}(z) = \frac{1}{2\pi}\int_{-\infty}^{\infty} e^{i(zt+t^3/3)}dt \tag{5}$$

and the INFINITE SERIES

$$\mathrm{Ai}(x) = \frac{1}{3^{2/3}\pi}\sum_{n=0}^{\infty}\frac{\Gamma\left(\frac{1}{3}(n+1)\right)}{n!} \times (3^{1/3}x)^n \sin\left[\frac{2(n+1)\pi}{3}\right] \tag{6}$$



(Banderier *et al.*). A generalization of the Airy function has been constructed by Hardy.
For $z = 0$,



$$\mathrm{Ai}(0) = \frac{1}{3^{2/3}\Gamma(\frac{2}{3})} \tag{7}$$

$$\mathrm{Bi}(0) = \frac{1}{3^{1/6}\Gamma(\frac{2}{3})}, \tag{8}$$

where $\Gamma(z)$ is the GAMMA FUNCTION.

The ASYMPTOTIC SERIES of Ai(z) has a different form in different QUADRANTS of the COMPLEX PLANE, a fact known as the STOKES PHENOMENON.

Functions related to the Airy functions have been defined as

$$\mathrm{Gi}(z) \equiv \frac{1}{\pi}\int_0^{\infty}\sin(\tfrac{1}{3}t^3 + zt)dt \tag{9}$$

$$\mathrm{Hi}(z) \equiv \frac{1}{\pi}\int_0^{\infty}\exp\left(-\tfrac{1}{3}t^3 + zt\right)dt, \tag{10}$$

where Gi(z) is defined for $\Im[z] \neq 0$ and Hi(z) for $\Re[z] \geq 0$. The can be expressed in terms of the Airy functions by

$$\begin{aligned}\mathrm{Gi}(z) = &-\frac{z^2}{2\pi}\,{}_1F_4\left(1 : \tfrac{2}{3}, \tfrac{5}{6}, \tfrac{7}{6}, \tfrac{4}{3}; \tfrac{1}{1296}z^6\right)\\ &+\frac{[\mathrm{sgn}(z)]^6}{360\pi z^6}\,{}_1F_4\left(1 : \tfrac{7}{6}, \tfrac{4}{3}, \tfrac{5}{3}, \tfrac{11}{6} : \tfrac{1}{1296}z^6\right) + \frac{z^6}{6|z|^6}\\ &\times[\mathrm{Bi}(-|z|) + \mathrm{Bi}(|z|)] - \frac{i\sqrt{3}|z|^3}{6z^4}[\mathrm{Ai}(-|z|) - \mathrm{Ai}(|z|)]\\ &+\frac{1}{6z^4|z|^6}\{\Im[z] + \Re[z][\mathrm{Bi}(|z|) - \mathrm{Bi}(-|z|)]\}\end{aligned} \tag{11}$$

$$\begin{aligned}\mathrm{Hi}(z) = &\tfrac{2}{3}\sqrt{-\tfrac{2}{3}}\left[J_{-1/3}\left(\tfrac{2}{3}(-z)^{3/2}\right) - J_{1/3}\left(\tfrac{2}{3}(-z)^{3/2}\right)\right]\\ &+\frac{z^2}{2\pi}\,{}_1F_2\left(1 : \tfrac{4}{3}, \tfrac{5}{3}, \tfrac{1}{9}z^3\right),\end{aligned} \tag{12}$$

where pF_q is a GENERALIZED HYPERGEOMETRIC FUNCTION, SGN is the sign function, $|z|$ is the MODULUS of z, $\Re[z]$ is the REAL PART, $\Im[z]$ is the IMAGINARY PART, and $J_n(z)$ is a BESSEL FUNCTION OF THE FIRST KIND.

Watson (1966, pp. 188–90) gives a slightly more general definition of the Airy function as the solution to the AIRY DIFFERENTIAL EQUATION

$$\Phi'' \pm k^2 \Phi x = 0 \tag{13}$$

which is FINITE at the ORIGIN, where Φ' denotes the DERIVATIVE $d\Phi/dx$, $k^2 = 1/3$, and either SIGN is permitted. Call these solutions $(1/\pi)\Phi(\pm k^2, x)$, then

$$\frac{1}{\pi}\Phi\left(\pm\tfrac{1}{3};\, x\right) \equiv \int_0^\infty \cos(t^3 \pm xt)\, dt \tag{14}$$

$$\Phi\left(\tfrac{1}{3};\, x\right) = \tfrac{1}{3}\pi\sqrt{\frac{x}{3}}\left[J_{-1/3}\left(\frac{2x^{3/2}}{3^{3/2}}\right) + J_{1/3}\left(\frac{2x^{3/2}}{3^{3/2}}\right)\right] \tag{15}$$

$$\Phi\left(-\tfrac{1}{3};\, x\right) = \tfrac{1}{3}\pi\sqrt{\frac{x}{3}}\left[I_{-1/3}\left(\frac{2x^{3/2}}{3^{3/2}}\right) - I_{1/3}\left(\frac{2x^{3/2}}{3^{3/2}}\right)\right], \tag{16}$$

where $J(z)$ is a BESSEL FUNCTION OF THE FIRST KIND. Using the identity

$$K_n(x) = \frac{\pi}{2}\frac{I_{-n}(x) - I_n(x)}{\sin(n\pi)}, \tag{17}$$

where $K(z)$ is a MODIFIED BESSEL FUNCTION OF THE SECOND KIND, the second case can be re-expressed

$$\Phi(-\tfrac{1}{3};\, x) = \tfrac{1}{3}\pi\sqrt{\frac{x}{3}}\,\frac{2}{\pi}\,\sin\left(\tfrac{1}{3}\pi\right) K_{1/3}\left(\frac{2x^{3/2}}{3^{3/2}}\right) \tag{18}$$

$$= \frac{\pi}{3}\sqrt{\frac{x}{3}}\,\frac{2}{\pi}\,\frac{\sqrt{3}}{2}\, K_{1/3}\left(\frac{2x^{3/2}}{3^{3/2}}\right) \tag{19}$$

$$= \frac{1}{3}\sqrt{x} K_{1/3}\left(\frac{2x^{3/2}}{3^{3/2}}\right). \tag{20}$$

Airy Projection

A MAP PROJECTION. The inverse equations for ϕ are computed by iteration. Let the ANGLE of the projection plane be θ_b. Define

$$a = \begin{cases} 0 & \text{for } \theta_b = \tfrac{1}{2}\pi \\ \dfrac{\ln[\tfrac{1}{2}\cos(\tfrac{1}{2}\pi - \theta_b)]}{\tan[\tfrac{1}{2}(\tfrac{1}{2}\pi - \theta_b)]} & \text{otherwise.} \end{cases} \tag{1}$$

For proper convergence, let $x_i = \pi/6$ and compute the initial point by checking

$$x_i = |\exp[-(\sqrt{x^2+y^2} + a\tan x_i)\tan x_i]|. \tag{2}$$

As long as $x_i > 1$, take $x_{i+1} = x_i/2$ and iterate again. The first value for which $x_i < 1$ is then the starting point. Then compute

$$x_i = \cos^{-1}\{\exp[-(\sqrt{x^2+y^2} + a\tan x_i)\tan x_i]\} \tag{3}$$

until the change in x_i between evaluations is smaller than the acceptable tolerance. The (inverse) equations are then given by

$$\phi = \tfrac{1}{2}\pi - 2x_i \tag{4}$$

$$\lambda = \tan^{-1}\left(-\frac{x}{y}\right). \tag{5}$$

AIRY FUNCTIONS

Airy-Fock Functions

The three Airy-Fock functions are

$$v(z) = \tfrac{1}{2}\sqrt{\pi}\,\mathrm{Ai}(z) \tag{1}$$

$$w_1(z) = 2e^{i\pi/6} v(\omega z) \tag{2}$$

$$w_2(z) = 2e^{-i\pi/6} v(\omega^{-1} z), \tag{3}$$

where $\mathrm{Ai}(z)$ is an AIRY FUNCTION. These functions satisfy

$$v(z) = \frac{\omega_1(z) - \omega_2(z)}{2i} \tag{4}$$

$$\overline{w_1(z)} = w_2(\bar{z}), \tag{5}$$

where $\bar{z}$ is the COMPLEX CONJUGATE of z.

Ajima-Malfatti Points

The lines connecting the vertices and corresponding circle-circle intersections in MALFATTI'S TANGENT TRIANGLE PROBLEM coincide in a point Y called the first Ajima-Malfatti point (Kimberling and MacDonald 1990, Kimberling 1994). Similarly, letting A'', B'', and C'' be the excenters of ABC, then the lines $A'A''$, $B'B''$, and $C'C''$ are coincident in another point called the second Ajima-Malfatti point. The points are sometimes simply called the malfatti points (Kimberling 1994).

Aleksandrov's Uniqueness Theorem

A convex body in EUCLIDEAN n-space that is centrally symmetric with center at the ORIGIN is determined among all such bodies by its brightness function (the VOLUME of each projection).

See also TOMOGRAPHY

References

Gardner, R. J. "Geometric Tomography." *Not. Amer. Math. Soc.* **42**, 422–29, 1995.

Aleksandrov-Cech Cohomology

A theory which satisfies all the EILENBERG-STEENROD AXIOMS with the possible exception of the LONG EXACT SEQUENCE OF A PAIR AXIOM, as well as a certain additional continuity CONDITION.

References

Hazewinkel, M. (Managing Ed.). *Encyclopaedia of Mathematics: An Updated and Annotated Translation of the*

Soviet "Mathematical Encyclopaedia." Dordrecht, Netherlands: Reidel, p. 68, 1988.

Aleph

The SET THEORY symbol ($\aleph$) for the CARDINALITY of an INFINITE SET.

See also ALEPH-0, ALEPH-1, COUNTABLE SET, COUNTABLY INFINITE, FINITE, INFINITE, TRANSFINITE NUMBER, UNCOUNTABLY INFINITE

Aleph-0

The SET THEORY symbol $\aleph_0$ for a SET having the same CARDINAL NUMBER as the "small" INFINITE SET of INTEGERS. The ALGEBRAIC NUMBERS also belong to $\aleph_0$. Rather surprising properties satisfied by $\aleph_0$ include

$$\aleph_0^r = \aleph_0 \qquad (1)$$

$$r\aleph_0 = \aleph_0 \qquad (2)$$

$$\aleph_0 + f = \aleph_0, \qquad (3)$$

where f is any FINITE SET. However,

$$\aleph_0^{\aleph_0} = C, \qquad (4)$$

where C is the CONTINUUM.

See also ALEPH-1, CARDINAL NUMBER, CONTINUUM, CONTINUUM HYPOTHESIS, COUNTABLY INFINITE, FINITE, INFINITE, TRANSFINITE NUMBER, UNCOUNTABLY INFINITE

Aleph-1

The SET THEORY symbol $\aleph_1$ for the smallest INFINITE SET larger than ALEPH-0, and equal to the CARDINALITY of the set of countable ORDINAL NUMBERS.

The CONTINUUM HYPOTHESIS asserts that $\aleph_1 = c$, where c is the CARDINALITY of the "large" INFINITE SET of REAL NUMBERS (called the CONTINUUM in SET THEORY). However, the truth of the CONTINUUM HYPOTHESIS depends on the version of SET THEORY you are using and so is UNDECIDABLE.

Curiously enough, n-D SPACE has the same number of points (c) as 1-D SPACE, or any FINITE INTERVAL of 1-D SPACE (a LINE SEGMENT), as was first recognized by Georg Cantor.

See also ALEPH-0, CARDINALITY, CONTINUUM, CONTINUUM HYPOTHESIS, COUNTABLY INFINITE, FINITE, INFINITE, ORDINAL NUMBER, TRANSFINITE NUMBER, UNCOUNTABLY INFINITE

Alethic

A term in LOGIC meaning pertaining to TRUTH and FALSEHOOD.

See also FALSE, PREDICATE, TRUE

Alexander Ideal

The order IDEAL in Λ, the RING of integral LAURENT POLYNOMIALS, associated with an ALEXANDER MATRIX for a KNOT K. Any generator of a principal Alexander ideal is called an ALEXANDER POLYNOMIAL. Because the ALEXANDER INVARIANT of a TAME KNOT in $\mathbb{S}^3$ has a SQUARE presentation MATRIX, its Alexander ideal is PRINCIPAL and it has an ALEXANDER POLYNOMIAL $\Delta(t)$.

See also ALEXANDER INVARIANT, ALEXANDER MATRIX, ALEXANDER POLYNOMIAL

References

Rolfsen, D. *Knots and Links.* Wilmington, DE: Publish or Perish Press, pp. 206–07, 1976.

Alexander Invariant

The Alexander invariant $H_*(\tilde{X})$ of a KNOT K is the HOMOLOGY of the INFINITE cyclic cover of the complement of K, considered as a MODULE over Λ, the RING of integral LAURENT POLYNOMIALS. The Alexander invariant for a classical TAME KNOT is finitely presentable, and only H_1 is significant.

For any KNOT K^n in $\mathbb{S}^{n+2}$ whose complement has the homotopy type of a FINITE COMPLEX, the Alexander invariant is finitely generated and therefore finitely presentable. Because the Alexander invariant of a TAME KNOT in $\mathbb{S}^3$ has a SQUARE presentation MATRIX, its ALEXANDER IDEAL is PRINCIPAL and it has an ALEXANDER POLYNOMIAL denoted $\Delta(t)$.

See also ALEXANDER IDEAL, ALEXANDER MATRIX, ALEXANDER POLYNOMIAL

References

Rolfsen, D. *Knots and Links.* Wilmington, DE: Publish or Perish Press, pp. 206–07, 1976.

Alexander Matrix

A presentation matrix for the ALEXANDER INVARIANT $H_1(\tilde{X})$ of a KNOT K. If V is a SEIFERT MATRIX for a TAME KNOT K in $\mathbb{S}^3$, then $V^T - tV$ and $V^T - tV^T$ are Alexander matrices for K, where V^T denotes the MATRIX TRANSPOSE.

See also ALEXANDER IDEAL, ALEXANDER INVARIANT, ALEXANDER POLYNOMIAL, SEIFERT MATRIX

References

Rolfsen, D. *Knots and Links.* Wilmington, DE: Publish or Perish Press, pp. 206–07, 1976.

Alexander Polynomial

A POLYNOMIAL invariant of a KNOT discovered in 1923 by J. W. Alexander (Alexander 1928). In technical language, the Alexander polynomial arises from the HOMOLOGY of the infinitely cyclic cover of a KNOT's complement. Any generator of a PRINCIPAL ALEXANDER IDEAL is called an Alexander polynomial (Rolfsen

1976). Because the ALEXANDER INVARIANT of a TAME KNOT in $\mathbb{S}^3$ has a SQUARE presentation MATRIX, its ALEXANDER IDEAL is PRINCIPAL and it has an Alexander polynomial denoted $\Delta(t)$.

Let Ψ be the MATRIX PRODUCT of BRAID WORDS of a KNOT, then

$$\frac{\det(1-\Psi)}{1+t+\ldots+t^{n-1}}=\Delta_L, \tag{1}$$

where Δ_L is the Alexander polynomial and det is the DETERMINANT. The Alexander polynomial of a TAME KNOT in $\mathbb{S}^3$ satisfies

$$\Delta(t) = \det(V^T - tV). \tag{2}$$

where V is a SEIFERT MATRIX, det is the DETERMINANT, and V^T denotes the MATRIX TRANSPOSE. The Alexander polynomial also satisfies

$$\Delta(1) = \pm 1. \tag{3}$$

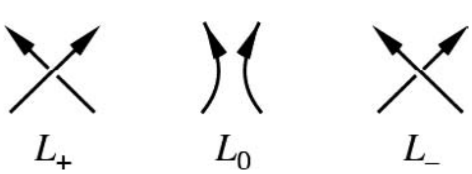
The Alexander polynomial of a splittable link is always 0. Surprisingly, there are known examples of nontrivial KNOTS with Alexander polynomial 1. An example is the $(-3,\ 5,\ 7)$ PRETZEL KNOT.

The Alexander polynomial remained the *only* known KNOT POLYNOMIAL until the JONES POLYNOMIAL was discovered in 1984. Unlike the Alexander polynomial, the more powerful JONES POLYNOMIAL *does,* in most cases, distinguish HANDEDNESS. A normalized form of the Alexander polynomial symmetric in t and t^{-1} and satisfying

$$\Delta(\text{unknot}) = 1 \tag{4}$$

was formulated by J. H. Conway and is sometimes denoted ∇_L. The NOTATION $[a+b+c+\ldots$ is an abbreviation for the Conway-normalized Alexander polynomial of a KNOT

$$a+b(x+x^{-1})+c(x^2+x^{-2})+\ldots \tag{5}$$



For a description of the NOTATION for LINKS, see Rolfsen (1976, p. 389). Examples of the Conway-Alexander polynomials for common KNOTS include

$$\nabla_{\text{TK}} = [1-1 = -x^{-1}+1-x \tag{6}$$

$$\nabla_{\text{FEK}} = [3-1 = -x^{-1}+3-x \tag{7}$$

$$\nabla_{\text{SSK}} = [1-1+1 = x^{-2}-x^{-1}+1-x+x^2 \tag{8}$$

for the TREFOIL KNOT, FIGURE-OF-EIGHT KNOT, and SOLOMON'S SEAL KNOT, respectively. Multiplying through to clear the NEGATIVE POWERS gives the usual Alexander polynomial, where the final SIGN is determined by convention.

Let an Alexander polynomial be denoted Δ, then there exists a SKEIN RELATIONSHIP (discovered by J. H. Conway)

$$\Delta_{L_+}(t)-\Delta_{L_-}(t)+(t^{-1/2}-t^{1/2})\Delta_{L_0}(t)=0 \tag{9}$$

corresponding to the above LINK DIAGRAMS (Adams 1994). A slightly different SKEIN RELATIONSHIP convention used by Doll and Hoste (1991) is

$$\nabla_{L_+}-\nabla_{L_-}=z\nabla_{L_0}. \tag{10}$$

These relations allow Alexander polynomials to be constructed for arbitrary knots by building them up as a sequence of over- and undercrossings.

For a KNOT,

$$\Delta_K(-1)\equiv\begin{cases}1(\text{mod } 8) & \text{if } \operatorname{Arf}(K)=0,\\ 5(\text{mod } 8) & \text{if } \operatorname{Arf}(K)=1,\end{cases} \tag{11}$$

where Arf is the ARF INVARIANT (Jones 1985). If K is a KNOT and

$$|\Delta_K(i)|>3. \tag{12}$$

then K cannot be REPRESENTED AS a closed 3-BRAID. Also, if

$$\Delta_K(e^{2\pi i/5})>\tfrac{13}{2}, \tag{13}$$

then K cannot be REPRESENTED AS a closed 4-braid (Jones 1985).

The HOMFLY POLYNOMIAL $P(a,\ z)$ generalizes the Alexander polynomial (as well at the JONES POLYNOMIAL) with

$$\nabla(z)=P(1,\ z) \tag{14}$$

(Doll and Hoste 1991).

Rolfsen (1976) gives a tabulation of Alexander polynomials for KNOTS up to 10 CROSSINGS and LINKS up to 9 CROSSINGS.

Alexander's Horned Sphere

The above solid, composed of a countable UNION of COMPACT SETS, is called Alexander's horned sphere. It is HOMEOMORPHIC with the BALL $\mathbb{B}^3$, and its boundary is therefore a SPHERE. It is therefore an example of a wild embedding in $\mathbb{E}^3$. The outer complement of the solid is not SIMPLY CONNECTED, and its fundamental GROUP is not finitely generated. Furthermore, the set of nonlocally flat ("bad") points of Alexander's horned sphere is a CANTOR SET.
The complement in $\mathbb{R}^3$ of the bad points for Alexander's horned sphere is SIMPLY CONNECTED, making it inequivalent to ANTOINE'S HORNED SPHERE. Alexander's horned sphere has an uncountable infinity of WILD POINTS, which are the limits of the sequences of the horned sphere's branch points (roughly, the "ends" of the horns), since any NEIGHBORHOOD of a limit contains a horned complex.

A humorous drawing by Simon Frazer (Guy 1983, Schroeder 1991, Albers 1994) depicts mathematician John H. Conway with Alexander's horned sphere growing from his head.

Alexander's Theorem

Any LINK can be represented by a closed BRAID.

Alexander-Conway Polynomial

CONWAY POLYNOMIAL

Alexander-Spanier Cohomology

A fundamental result of DE RHAM COHOMOLOGY is that the kth DE RHAM COHOMOLOGY VECTOR SPACE of a MANIFOLD M is canonically isomorphic to the Alexander-Spanier cohomology VECTOR SPACE $H^k(M;\mathbb{R})$ (also called cohomology with compact support). In the case that M is COMPACT, Alexander-Spanier cohomology is exactly "singular" COHOMOLOGY.

Algebra

The branch of mathematics dealing with such topics as GROUP THEORY, invariant theory, and COHOMOLOGY which studies number systems and operations within them. The word "algebra" is a distortion of the Arabic title of a treatise by al-Khwarizmi about algebraic methods. Note that mathematicians refer to the "school algebra" generally taught in middle and high school as "ARITHMETIC," reserving the word "algebra" for the more advanced aspects of the subject.

Formally, an algebra is a VECTOR SPACE V, over a FIELD F with a MULTIPLICATION which turns it into a RING defined such that, if $f \in F$ and $x,\ y \in V$, then

$$f(xy) = (fx)y = x(fy).$$

In addition to the usual algebra of REAL NUMBERS, there are ≈ 1151 additional CONSISTENT algebras which can be formulated by weakening the FIELD AXIOMS, at least 200 of which have been *rigorously* proven to be self-CONSISTENT (Bell 1945).

Algebras which have been investigated and found to be of interest are usually named after one or more of their investigators. This practice leads to exotic-sounding (but unenlightening) names which algebraists frequently use with minimal or nonexistent explanation.

Algebraic Closure

The FIELD $\bar{F}$ is called an algebraic closure of F if $\bar{F}$ is algebraic over F and if every polynomial $f(x) \in F[x]$ SPLITS completely over $\bar{F}$, so that $\bar{F}$ can be said to contain all the elements that are algebraic over F.

For example, the FIELD of COMPLEX NUMBERS $\mathbb{C}$ is the algebraic closure of the FIELD of REALS $\mathbb{R}$.

Algebraic Curve

An algebraic curve over a FIELD K is an equation $f(X, Y)=0$, where $f(X, Y)$ is a POLYNOMIAL in X and Y with COEFFICIENTS in K. A nonsingular algebraic curve is an algebraic curve over K which has no SINGULAR POINTS over K. A point on an algebraic curve is simply a solution of the equation of the curve. A K-RATIONAL POINT is a point (X, Y) on the curve, where X and Y are in the FIELD K.

Algebraic Function Field

FUNCTION FIELD

Algebraic Geometry

Algebraic geometry is the study of geometries that come from algebra, in particular, from RINGS. In CLASSICAL ALGEBRAIC GEOMETRY, the algebra is the RING of POLYNOMIALS, and the geometry is the set of zeros of polynomials, called an ALGEBRAIC VARIETY. For instance, the UNIT CIRCLE is the set of zeros of $x^2+y^2=1$ and is an ALGEBRAIC VARIETY, as are all of the CONIC SECTIONS.

In the twentieth century, it was discovered that the basic ideas of classical algebraic geometry can be applied to any COMMUTATIVE RING with a unit, such as the INTEGERS. The geometry of such a ring is determined by its algebraic structure, in particular its PRIME IDEALS. Grothendieck defined SCHEMES as the basic geometric objects, which have the same relationship to the geometry of a ring as a MANIFOLD to a COORDINATE CHART. The language of CATEGORY THEORY evolved at around the same time, largely in response to the needs of the increasing abstraction in algebraic geometry.

As a consequence, algebraic geometry became very useful in other areas of mathematics, most notably in ALGEBRAIC NUMBER THEORY. For instance, Deligne used it to prove a variant of the RIEMANN HYPOTHESIS. Also, Andrew Wiles' proof of FERMAT'S LAST THEOREM used the tools developed in algebraic geometry.

In the latter part of the twentieth century, researchers have tried to extend the relationship between algebra and geometry to arbitrary NONCOMMUTATIVE RINGS. The study of geometries associated to noncommutative rings is called NONCOMMUTATIVE GEOMETRY.

Algebraic Integer

If r is a ROOT of the POLYNOMIAL equation

$$x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0 = 0,$$

where the a_is are INTEGERS and r satisfies no similar equation of degree $< n$, then r is called an algebraic integer of degree n. An algebraic integer is a special case of an ALGEBRAIC NUMBER (for which the leading COEFFICIENT a_n need not equal 1). RADICAL INTEGERS are a SUBRING of the algebraic integers.

A SUM or PRODUCT of algebraic integers is again an algebraic integer. However, ABEL'S IMPOSSIBILITY THEOREM shows that there are algebraic integers of degree ≥ 5 which are not expressible in terms of ADDITION, SUBTRACTION, MULTIPLICATION, DIVISION, and ROOT EXTRACTION (the ELEMENTARY OPERATIONS) on COMPLEX NUMBERS. In fact, if ELEMENTARY OPERATIONS are allowed on real numbers only, then there are real numbers which are algebraic integers of degree 3 which cannot be so expressed.

The GAUSSIAN INTEGERS are algebraic integers of $\mathbb{Q}(\sqrt{-1})$, since $a + bi$ are roots of

$$z^2 - 2az + a^2 + b^2 = 0.$$

Algebraic K-Theory

K-THEORY

Algebraic Language

Let X be an alphabet (i.e., a finite and nonempty set), and call its member letters. A word on X is a finite sequence of letters $a_1 \ldots a_n$, where $a_1, \ldots, a_n \in X$. Denote the empty word by e, and the set of all words in X by X^*. Define the concatenation (also called product) of a word $u = a_1 \ldots a_n$ with a word $v = b_1 \ldots b_m$ as $uv = a_1 \ldots a_n b_1 \ldots b_m$. In general, concatenation is not commutative. Use the notation $|u|_a$ to mean the number of letters a in the word u. A language $\mathfrak{L}$ is then a subset of X^*, and $\mathfrak{L}$ is said to be algebraic when a set of rewriting rules, applied recursively, forms all the words of $\mathfrak{L}$ and no others.

Algebraic Manifold

An algebraic manifold is another name for a smooth ALGEBRAIC VARIETY. It can be covered by COORDINATE CHARTS so that the TRANSITION FUNCTIONS are given by RATIONAL FUNCTIONS. Technically speaking, the coordinate charts should be to all of affine space $\mathbb{C}^n$.

For example, the SPHERE is an algebraic manifold, with a chart given by STEREOGRAPHIC PROJECTION to $\mathbb{C}$, and another chart at ∞, with the TRANSITION FUNCTION given by $1/z$. In this setting, it is called the RIEMANN SPHERE. The TORUS is also an algebraic manifold, in this setting called an ELLIPTIC CURVE, with charts given by ELLIPTIC FUNCTIONS such as the WEIERSTRASS ELLIPTIC FUNCTION.

See also ABSTRACT MANIFOLD, ALGEBRAIC GEOMETRY, ALGEBRAIC VARIETY, ELLIPTIC CURVE, MANIFOLD

Algebraic Number

If r is a ROOT of the POLYNOMIAL equation

$$a_0x^n + a_1x^{n-1} + \cdots + a_{n-1}x + a_n = 0, \qquad (1)$$

where the a_is are INTEGERS and r satisfies no similar equation of degree $< n$, then r is an algebraic number of degree n. If r is an algebraic number and $a_0 = 1$, then it is called an ALGEBRAIC INTEGER. It is also true that if the c_is in

$$a_0x^n + c_1x^{n-1} + \cdots + c_{n-1}x + c_n = 0 \qquad (2)$$

are algebraic numbers, then any ROOT of this equation is also an algebraic number.

If α is an algebraic number of degree n satisfying the POLYNOMIAL

$$a(x-\alpha)(x-\beta)(x-\gamma)\ldots, \qquad (3)$$

then there are $n-1$ other algebraic numbers β, γ, ... called the conjugates of α. Furthermore, if α satisfies any other algebraic equation, then its conjugates also satisfy the same equation (Conway and Guy 1996).

Any number which is not algebraic is said to be TRANSCENDENTAL. The set of algebraic numbers is denoted $\mathbb{A}$ (*Mathematica*), or sometimes $\bar{\mathbb{Q}}$ (Nesterenko 1999), and is implemented in *Mathematica* as `Algebraics`. A number x can then be tested to see if it is algebraic using the command `Element[`x`, Algebraics]`.

NUMBER FIELD

Algebraic Number Theory

NUMBER THEORY

Algebraic Projective Geometry

PROJECTIVE GEOMETRY

Algebraic Set

An algebraic set is the locus of zeros of a collection of POLYNOMIALS. For example, the circle is the set of zeros of x^2+y^2-1 and the point at (a, b) is the set of zeros of x and y. The algebraic set $\{(x, 0)\} \cup \{(0, y)\}$ is the set of solutions to $xy=0$. It decomposes into two irreducible algebraic sets, called ALGEBRAIC VARIETIES. In general, an algebraic set can be written uniquely as the finite union of ALGEBRAIC VARIETIES.

The intersection of two algebraic sets is an algebraic set corresponding to the union of the polynomials. For example, $x=0$ and $y=0$ intersect at $(0, 0)$, i.e., where $x=0$ and $y=0$. In fact, the intersection of an arbitrary number of algebraic sets is itself an algebraic set. However, only a finite union of algebraic sets is algebraic. If X is the set of solutions to $f_i=0$ and Y is the set of solutions to $g_j=0$, then $X \cup Y$ is the set of solutions to $f_i g_j=0$. Consequently, the algebraic sets are the closed sets in a TOPOLOGY, called the ZARISKI TOPOLOGY.

The set of polynomials vanishing on an algebraic set X is an IDEAL in the POLYNOMIAL RING. Conversely, any IDEAL defines an algebraic set since it is a collection of polynomials. HILBERT'S NULLSTELLENSATZ describes the precise relationship between IDEALS and algebraic sets.

Algebraic Surface

The set of ROOTS of a POLYNOMIAL $f(x, y, z)=0$. An algebraic surface is said to be of degree $n=\max(i+j+k)$, where n is the maximum sum of powers of all terms $a_m x^{i_m} y^{j_m} z^{k_m}$. The following table lists the names of algebraic surfaces of a given degree.

Order	Surface
3	CUBIC SURFACE
4	QUARTIC SURFACE
5	QUINTIC SURFACE
6	SEXTIC SURFACE
7	HEPTIC SURFACE
8	OCTIC SURFACE
9	NONIC SURFACE
10	DECIC SURFACE
12	DODECIC SURFACE

Algebraic Topology

The study of intrinsic qualitative aspects of spatial objects (e.g., SURFACES, SPHERES, TORI, CIRCLES, KNOTS, LINKS, configuration spaces, etc.) that remain invariant under both-directions continuous ONE-TO-ONE (HOMEOMORPHIC) transformations. The discipline of algebraic topology is popularly known as "RUBBER-SHEET GEOMETRY" and can also be viewed as the study of DISCONNECTIVITIES. Algebraic topology has a great deal of mathematical machinery for

studying different kinds of HOLE structures, and it gets the prefix "algebraic" since many HOLE structures are represented best by algebraic objects like GROUPS and RINGS.

A technical way of saying this is that algebraic topology is concerned with FUNCTORS from the topological CATEGORY of GROUPS and HOMOMORPHISMS. Here, the FUNCTORS are a kind of filter, and given an "input" SPACE, they spit out something else in return. The returned object (usually a GROUP or RING) is then a representation of the HOLE structure of the SPACE, in the sense that this algebraic object is a vestige of what the original SPACE was like (i.e., much information is lost, but some sort of "shadow" of the SPACE is retained–just enough of a shadow to understand some aspect of its HOLE-structure, but no more). The idea is that FUNCTORS give much simpler objects to deal with. Because SPACES by themselves are very complicated, they are unmanageable without looking at particular aspects.

COMBINATORIAL TOPOLOGY is a special type of algebraic topology that uses COMBINATORIAL methods.

Algebraic Unknotting Number

The algebraic unknotting number of a knot K in $\mathbb{S}^3$ is defined as the algebraic unknotting number of the S-equivalence class of a SEIFERT MATRIX of K. The algebraic unknotting number of an element in an S-equivalent class is defined as the minimum number of algebraic unknotting operations necessary to transform the element to the S-equivalence class of the zero matrix (Saeki 1999).

Algebraic Variety

A generalization to n-D of ALGEBRAIC CURVES. More technically, an algebraic variety is a reduced SCHEME of FINITE type over a FIELD K. An algebraic variety V is defined as the SET of points in the REALS $\mathbb{R}^n$ (or the COMPLEX NUMBERS $\mathbb{C}^n$) satisfying a system of POLYNOMIAL equations $f_i(x_1, \ldots, x_n)=0$ for $i=1, 2, \ldots$. According to the HILBERT BASIS THEOREM, a FINITE number of equations suffices.

A variety is the set of common zeros to a collection of POLYNOMIALS. In classical algebraic geometry, the polynomials have COMPLEX NUMBERS for coefficients. Because of the FUNDAMENTAL THEOREM OF ALGEBRA, such polynomials always have zeros. For example,

$$\{(x, y, z) : x^2+y^2-z^2\}$$

is the CONE, and

$$\{(x, y, z) : x^2+y^2-z^2,\ ax+by+cz=0\}$$

is a CONIC SECTION, which is a SUBVARIETY of the cone.

Actually, the cone and the conic section are examples of AFFINE VARIETIES because they are in AFFINE SPACE. A general variety is comprised of affine varieties glued together, like the COORDINATE CHARTS of a MANIFOLD. The FIELD of coefficients can be any ALGEBRAICALLY CLOSED field. When a variety is embedded in projective space, it is a PROJECTIVE ALGEBRAIC VARIETY. Also, an INTRINSIC VARIETY can be thought of as an abstract object, like a MANIFOLD, independent of any particular embedding. A SCHEME is a generalization of a variety, which includes the possibility of replacing $\mathbb{C}[x, y, z]$ by any COMMUTATIVE RING with a unit. A further generalization is a STACK.

Algebraically Independent

This entry contributed by JOHNNY CHEN

Let K be a FIELD, and A a K-algebra. Elements y_1, ..., y_n are algebraically independent over K if the natural surjection $K[Y_1, \ldots, Y_n] \to K[y_1, \ldots y_n]$ is an isomorphism. In other words, there are no polynomial relations $F(y_1, \ldots, y_n) = 0$ with coefficients in K.

Algebraics

ALGEBRAIC NUMBER

Algebroidal Function

An ANALYTIC FUNCTION $f(z)$ satisfying the irreducible algebraic equation

$$A_0(z)f^k + A_1(z)f^{k-1} + \cdots + A_k(z) = 0$$

with single-valued MEROMORPHIC FUNCTIONS $A_j(z)$ in a COMPLEX DOMAIN G is called a k-algebroidal function in G.

Algorithm

A specific set of instructions for carrying out a procedure or solving a problem, usually with the requirement that the procedure terminate at some point. Specific algorithms sometimes also go by the name METHOD, PROCEDURE, or TECHNIQUE. The word "algorithm" is a distortion of al-Khwarizmi, an Arab mathematician who wrote an influential treatise about algebraic methods.

Algorithmic Complexity

BIT COMPLEXITY, KOLMOGOROV COMPLEXITY

Alhazen's Billiard Problem

In a given CIRCLE, find an ISOSCELES TRIANGLE whose LEGS pass through two given POINTS inside the CIRCLE. This can be restated as: from two POINTS in the PLANE of a CIRCLE, draw LINES meeting at the POINT of the CIRCUMFERENCE and making equal ANGLES with the NORMAL at that POINT.

The problem is called the billiard problem because it corresponds to finding the POINT on the edge of a circular "BILLIARD" table at which a cue ball at a given POINT must be aimed in order to carom once off the edge of the table and strike another ball at a second given POINT. The solution leads to a BIQUADRATIC EQUATION OF THE FORM

$$H(x^2-y^2)-2Kxy+(x^2+y^2)(hy-kx)=0.$$

The problem is equivalent to the determination of the point on a spherical mirror where a ray of light will reflect in order to pass from a given source to an observer. It is also equivalent to the problem of finding, given two points and a CIRCLE such that the points are both inside or outside the CIRCLE, the ELLIPSE whose FOCI are the two points and which is tangent to the given CIRCLE.

The problem was first formulated by Ptolemy in 150 AD, and was named after the Arab scholar Alhazen, who discussed it in his work on optics. It was not until 1997 that Neumann proved the problem to be insoluble using a COMPASS and RULER construction because the solution requires extraction of a CUBE ROOT (Neumann 1998). This is the same reason that the CUBE DUPLICATION problem is insoluble.

Alhazen's Problem

ALHAZEN'S BILLIARD PROBLEM

Alias Transformation

A transformation in which the coordinate system is changed, leaving vectors in the original coordinate system "fixed" while changing their representation in the new coordinate system. In contrast, a transformation in which vectors are transformed in a fixed coordinate system is called an ALIBI TRANSFORMATION.

See also ALIBI TRANSFORMATION, ROTATION FORMULA

Aliasing

Given a power spectrum (a plot of power vs. frequency), aliasing is a false translation of power falling in some frequency range $(-f_c, f_c)$ outside the range. Aliasing can be caused by discrete sampling below the NYQUIST FREQUENCY. The sidelobes of any INSTRUMENT FUNCTION (including the simple SINC SQUARED function obtained simply from FINITE sampling) are also a form of aliasing. Although sidelobe contribution at large offsets can be minimized with the use of an APODIZATION FUNCTION, the tradeoff is a widening of the response (i.e., a lowering of the resolution).

See also APODIZATION FUNCTION, NYQUIST FREQUENCY

Alibi Transformation

A transformation in which vectors are transformed in a fixed coordinate system. In contrast, a transformation in which the coordinate system is changed, leaving vectors in the original coordinate system "fixed" while changing their representation in the new coordinate system, is called an ALIAS TRANSFORMATION.

See also ALIAS TRANSFORMATION, ROTATION FORMULA

Aliquant Divisor

A number which does not DIVIDE another exactly. For instance, 4 and 5 are aliquant divisors of 6. A number which is not an aliquant divisor (i.e., one that *does* DIVIDE another exactly) is said to be an ALIQUOT DIVISOR.

See also ALIQUOT DIVISOR, DIVISOR, PROPER DIVISOR

Aliquot Cycle

ALIQUOT SEQUENCE, SOCIABLE NUMBERS

Aliquot Divisor

A number which DIVIDES another exactly. For instance, 1, 2, 3, and 6 are aliquot divisors of 6. A number which is not an aliquot divisor is said to be an ALIQUANT DIVISOR. The term "aliquot" is frequently used to specifically mean a PROPER DIVISOR, i.e., a DIVISOR of a number other than the number itself.

See also ALIQUANT DIVISOR, DIVISOR, PROPER DIVISOR

Aliquot Sequence

Let

$$s(n) \equiv \sigma(n) - n$$

where $\sigma(n)$ is the DIVISOR FUNCTION and $s(n)$ is the RESTRICTED DIVISOR FUNCTION. Then the SEQUENCE of numbers

$$s^0(n) \equiv n,\ s^1(n) = s(n),\ s^2(n) = s(s(n)), \cdots$$

is called an aliquot sequence. If the SEQUENCE for a given n is bounded, it either ends at $s(1) = 0$ or becomes periodic.

1. If the SEQUENCE reaches a constant, the constant is known as a PERFECT NUMBER.
2. If the SEQUENCE reaches an alternating pair, it is called an AMICABLE PAIR.
3. If, after k iterations, the SEQUENCE yields a cycle of minimum length t OF THE FORM $s^{k+1}(n)$, $s^{k+2}(n)$, ..., $s^{k+1}(n)$, then these numbers form a group of SOCIABLE NUMBERS of order t.

It has not been proven that all aliquot sequences eventually terminate and become period. The smallest number whose fate is not known is 276, which has been computed up to $s^{628}(276)$ (Guy 1994). There are five such sequences less than 1000, namely 276, 552, 564, 660, and 966, sometimes called the "Lehmer five." Furthermore, there are 934 open sequences $\leq 10^5$, and 9710 open sequences $\leq 10^6$ (Creyaufmüller).

See also 196-ALGORITHM, ADDITIVE PERSISTENCE, AMICABLE NUMBERS, CATALAN'S ALIQUOT SEQUENCE CONJECTURE, MULTIAMICABLE NUMBERS, MULTIPERFECT NUMBER, MULTIPLICATIVE PERSISTENCE, PERFECT NUMBER, SOCIABLE NUMBERS, UNITARY ALIQUOT SEQUENCE

Alladi-Grinstead Constant

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Let $N(n)$ be the number of ways in which the FACTORIAL $n!$ can be decomposed into n FACTORS of the form $P_k^{b_k}$ arranged in nondecreasing order. Also define

$$m(n) \equiv \max(p_1^{b_1}), \tag{1}$$

i.e., $m(n)$ is the LEAST PRIME FACTOR raised to its appropriate POWER in the factorization. Then define

$$\alpha(n) \equiv \frac{\ln m(n)}{\ln n} \tag{2}$$

where $\ln(x)$ is the NATURAL LOGARITHM. For instance,

$$\begin{aligned} 9! &= 2 \cdot 2 \cdot 2 \cdot 2 \cdot 2 \cdot 2^2 \cdot 5 \cdot 7 \cdot 3^4 \\ &= 2 \cdot 2 \cdot 2 \cdot 2 \cdot 3 \cdot 5 \cdot 7 \cdot 2^3 \cdot 3^3 \\ &= 2 \cdot 2 \cdot 2 \cdot 2 \cdot 5 \cdot 7 \cdot 2^3 \cdot 3^2 \cdot 3^2 \\ &= 2 \cdot 2 \cdot 2 \cdot 3 \cdot 2^2 \cdot 2^2 \cdot 5 \cdot 7 \cdot 3^3 \\ &= 2 \cdot 2 \cdot 2 \cdot 2^2 \cdot 2^2 \cdot 5 \cdot 7 \cdot 3^2 \cdot 3^2 \\ &= 2 \cdot 2 \cdot 2 \cdot 3 \cdot 3 \cdot 5 \cdot 7 \cdot 3^2 \cdot 2^4 \\ &= 2 \cdot 2 \cdot 3 \cdot 3 \cdot 2^2 \cdot 5 \cdot 7 \cdot 2^3 \cdot 3^2 \\ &= 2 \cdot 2 \cdot 3 \cdot 3 \cdot 3 \cdot 3 \cdot 5 \cdot 7 \cdot 2^5 \\ &= 2 \cdot 3 \cdot 3 \cdot 2^2 \cdot 2^2 \cdot 2^2 \cdot 5 \cdot 7 \cdot 3^2 \\ &= 2 \cdot 3 \cdot 3 \cdot 3 \cdot 3 \cdot 2^2 \cdot 5 \cdot 7 \cdot 2^4 \\ &= 2 \cdot 3 \cdot 3 \cdot 3 \cdot 3 \cdot 5 \cdot 7 \cdot 2^3 \cdot 2^3 \\ &= 3 \cdot 3 \cdot 3 \cdot 3 \cdot 2^2 \cdot 2^2 \cdot 5 \cdot 7 \cdot 2^3, \end{aligned} \tag{3}$$

so

$$\alpha(9) = \frac{\ln 3}{\ln 9} = \frac{\ln 3}{2 \ln 3} = \frac{1}{2}. \tag{4}$$

For large n,

$$\lim_{n \to \infty} \alpha(n) = e^{c-1} = 0.809394020534..., \tag{5}$$

where

$$c \equiv \sum_{k=2}^{\infty} \frac{1}{k} \ln\left(\frac{k}{k-1}\right). \tag{6}$$

Allais Paradox

Choose between the following two alternatives:

1. 90% chance of an unknown amount x and a 10% chance of \$1 million, or
2. 89% chance of the same unknown amount x, 10% chance of \$2.5 million, and 1% chance of nothing.

The PARADOX is to determine which choice has the larger EXPECTATION VALUE, $0.9x+\$100,000$ or $0.89x+\$250,000$. However, the best choice depends on the unknown amount, even though it is the same in both cases! This appears to violate the INDEPENDENCE AXIOM.

All-Pairs Shortest Path

The shortest distance between any pair of vertices in the shortest-path spanning tree, as long as the path giving the shortest path does not pass through the root of the spanning tree (Skiena 1990, p. 228). The problem can be solved using n applications of DIJKSTRA'S ALGORITHM or FLOYD'S ALGORITHM. The latter also works in the case of a weighted graph where the edges have negative weights.

All-Poles Model

MAXIMUM ENTROPY METHOD

All-to-All Communication

GOSSIPING

Almost All

Given a property P, if $P(x) \sim x$ as $x \to \infty$ (so the number of numbers less than x not satisfying the property P is $o(x)$), then P is said to hold true for almost all numbers. For example, almost all positive integers are COMPOSITE NUMBERS (which is not in conflict with the second of EUCLID'S THEOREMS that there are an infinite number of PRIMES).

Almost Alternating Knot

An ALMOST ALTERNATING LINK with a single component.

See also ALMOST ALTERNATING LINK

Almost Alternating Link

Call a projection of a LINK an almost alternating projection if one crossing change in the projection makes it an alternating projection. Then an almost alternating link is a LINK with an almost alternating projection, but no alternating projection. Every ALTERNATING KNOT has an almost alternating projection. A PRIME KNOT which is almost alternating is either a TORUS KNOT or a HYPERBOLIC KNOT. Therefore, no SATELLITE KNOT is an almost alternating knot.

All nonalternating 9-crossing PRIME KNOTS are almost alternating. Of the 393 nonalternating knots and links with 11 or fewer crossings, all but five are known to be almost alternating (and 3 of these have 11 crossings). The fate of the remaining five is not known. The $(q, 2)$, $(4, 3)$, and $(5, 3)$-TORUS KNOTS are almost alternating (Adams 1994, p. 142).

Almost Everywhere Convergence

A weakened version of POINTWISE CONVERGENCE hypothesis which states that, for X a MEASURE SPACE, $f_n(x) \to f(x)$ for all $x \in Y$, where Y is a measurable subset of X such that $\mu(X \setminus Y) = 0$.

See also POINTWISE CONVERGENCE

References

Browder, A. *Mathematical Analysis: An Introduction.* New York: Springer-Verlag, 1996.

Almost Integer

A number which is very close to an INTEGER. One surprising example involving both E and PI is

$$e^\pi - \pi = 19.999099979\ldots \quad (1)$$

which can also be written as

$$(\pi + 20)^i = -0.9999999992 - 0.0000388927i \approx -1 \quad (2)$$

$$\cos(\ln(\pi + 20)) \approx -0.9999999992. \quad (3)$$

Applying COSINE a few more times gives

$$\cos(\pi \cos(\pi \cos(\ln(\pi + 20)))) \approx -1 + 3.9321609261 \times 10^{-35}. \quad (4)$$

This curious near-identity was apparently noticed almost simultaneously around 1988 by N. J. A. - Sloane, J. H. Conway, and S. Plouffe, but no satisfying explanation as to "why" it has been true has yet been discovered.

An interesting near-identity is given by

$$\frac{1}{4}\left[\cos\left(\tfrac{1}{10}\right) + \cosh\left(\tfrac{1}{10}\right) + 2\cos\left(\tfrac{1}{20}\sqrt{2}\right)\cosh\left(\tfrac{1}{20}\sqrt{2}\right)\right] = 1 + 2.480\ldots \times 10^{-13} \quad (5)$$

(W. Dubuque). Other remarkable near-identities are given by

$$\frac{5(1+\sqrt{5})[\Gamma\left(\frac{3}{4}\right)]^2}{e^{5x/6}\sqrt{\pi}} = 1 + 4.5422\ldots \times 10^{-14} \quad (6)$$

where $\Gamma(z)$ is the GAMMA FUNCTION (S. Plouffe),

$$e^6 - \pi^4 - \pi^5 = 0.000017673\ldots \quad (7)$$

(D. Wilson),

$$r\left(\frac{160}{\pi}\right)^{1/13} \approx 0.9999996766, \quad (8)$$

where $r \approx 0.739085$ is the root of $x = \cos x$ (L. A. Broukhis),

$$\ln 2 + \log_{10} 2 = 0.994177\ldots \quad (9)$$

(D. Davis),

$$\frac{163}{\ln 163} = 31.9999983738\ldots \quad (10)$$

(posted to `sci.math`; origin unknown),

$$eK^{5/7-\gamma}\pi^{-(2/7+\gamma)} \approx 1.00014678 \quad (11)$$

$$\frac{K^{\gamma-19/7}\pi^{2/7+\gamma}}{2\phi} \approx 1.00105 \quad (12)$$

$$e\gamma\phi(K\pi)^{-(2/7+\gamma)} \approx 1.01979, \quad (13)$$

where K is CATALAN'S CONSTANT, γ is the EULER-MASCHERONI CONSTANT, and ϕ is the GOLDEN RATIO (D. Barron), and

$$163(\pi - e) = 68.999664\ldots \quad (14)$$

$$\frac{53453}{\ln 53453} = 4910.00000122\ldots \quad (15)$$

$$\left[(2-1)^2 + \frac{(5^2-1)^2}{6^2+1}\right]e - \left[(2+1)^2 + \frac{(5^2+1)^2}{6^2-1}\right]^{-1} = \tfrac{613}{37}e - \tfrac{35}{991} = 44.99999999993962\ldots \quad (16)$$

(Stoschek). Stoschek also gives an interesting near-identity involving the fine structure constant α and FEIGENBAUM CONSTANT δ,

$$(28 - \delta^{-1})(\alpha^{-1} - 137) \approx 0.999998. \quad (17)$$

The near identity

$$3\sqrt{2}(\sqrt{5} - 2) = 1.0015516\ldots \quad (18)$$

arises by noting that the stellation ratio $3(\sqrt{5} - 2)$ in the CUMULATION of the DODECAHEDRON to form the GREAT DODECAHEDRON is approximately equal to $\sqrt{2}$.

A set of almost integers due to D. Hickerson are those OF THE FORM

$$h_n = \frac{n!}{2(\ln 2)^{n+1}}. \quad (19)$$

for $1 \le n \le 15$, as summarized in the following table.

n	h_n
0	0.72135
1	1.04068
2	3.00278
3	12.99629
4	74.99874
5	541.00152
6	4683.00125
7	47292.99873
8	545834.99791
9	7087261.00162
10	102247563.00527
11	1622632572.99755
12	28091567594.98157
13	526858348381.00125
14	10641342970443.08453
15	230283190977853.03744
16	5315654681981354.51308
17	130370767029135900.45799

These numbers are close to integers due to the fact that the quotient is the dominant term in an infinite series for the number of possible outcomes of a race between n people (with ties are allowed). Calling this number $f(n)$, it follows that

$$f(n)=\sum_{k=1}^{n}\binom{n}{k}f(n-k) \qquad (20)$$

for $n \geq 1$, where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT. From this, we obtain the exponential generating function for f

$$\sum_{n=0}^{\infty}\frac{f(n)}{n!}z^n=\frac{1}{2-e^z}, \qquad (21)$$

and then by CONTOUR INTEGRATION it can be shown that

$$f(n)=\tfrac{1}{2}n!\sum_{k=-\infty}^{\infty}\frac{1}{(\ln 2+2\pi ik)^{n+1}} \qquad (22)$$

for $n \geq 1$, where i is the square root of -1 and the sum is over all integers k (here, the imaginary parts of the terms for k and $-k$ cancel each other, so this sum is real.) The $k = 0$ term dominates, so $f(n)$ is asymptotic to $n!/(2(\ln 2)^{n+1})$. In fact, the other terms are quite small for n from 1 to 15, so $f(n)$ is the nearest integer to $n!/(2(\ln 2)^{n+1})$ for these values (Hickerson), given by the sequence 1, 3, 13 75, 541, 4683, ... (Sloane's A034172).

A large class of IRRATIONAL "almost integers" can be found using the theory of MODULAR FUNCTIONS, and a few rather spectacular examples are given by Ramanujan (1913–4). Such approximations were also studied by Hermite (1859), Kronecker (1863), and Smith (1965). They can be generated using some amazing (and very deep) properties of the j-FUNCTION. Some of the numbers which are closest approximations to INTEGERS are $e^{\pi\sqrt{163}}$ (sometimes known as the RAMANUJAN CONSTANT and which corresponds to the field $\mathbb{Q}(\sqrt{-163})$ which has CLASS NUMBER 1 and is the IMAGINARY QUADRATIC FIELD of maximal discriminant), $e^{\pi\sqrt{22}}$, $e^{\pi\sqrt{37}}$, and $e^{\pi\sqrt{58}}$, the last three of which have CLASS NUMBER 2 and are due to Ramanujan (Berndt 1994, Waldschmidt 1988).

The properties of the j-FUNCTION also give rise to the spectacular identity

$$\left[\frac{\ln(640320^3+744)}{\pi}\right]^2=163+2.32167\ldots\times 10^{-29} \qquad (23)$$

(Le Lionnais 1983, p. 152).

The list below gives numbers OF THE FORM $x \equiv e^{\pi\sqrt{n}}$ for $n \leq 1000$ for which $[x]-x \leq 0.01$.

$e^{\pi\sqrt{6}}=2,\ 197.990869543\ldots$

$e^{\pi\sqrt{17}}=422,\ 150.997675680\ldots$

$e^{\pi\sqrt{18}}=614,\ 551.992885619\ldots$

$e^{\pi\sqrt{22}}=2,\ 508,\ 951.998257424\ldots$

$e^{\pi\sqrt{25}}=6,\ 635,\ 623.999341134\ldots$

$e^{\pi\sqrt{37}}=199,\ 148,\ 647.999978046551\ldots$

$e^{\pi\sqrt{43}}=884,\ 736,\ 743.999777466\ldots$

$e^{\pi\sqrt{58}}=24,\ 591,\ 257,\ 751.999999822213\ldots$

$e^{\pi\sqrt{59}}=30,\ 197,\ 683,\ 486.993182260\ldots$

$e^{\pi\sqrt{67}}=147,\ 197,\ 952,\ 743.999998662454\ldots$

$e^{\pi\sqrt{74}}=545,\ 518,\ 122,\ 089.999174678853\ldots$

$e^{\pi\sqrt{149}}=45,\ 116,\ 546,\ 012,\ 289,\ 599.991830287\ldots$

$e^{\pi\sqrt{163}}=262,\ 537,\ 412,\ 640,\ 768,\ 743.999999999999250072\ldots$

$e^{\pi\sqrt{177}}=1,\ 418,\ 556,\ 986,\ 635,\ 586,\ 485.996179355\ldots$

$e^{\pi\sqrt{232}}=604,\ 729,\ 957,\ 825,\ 300,\ 084,\ 759.999992171526\ldots$

$e^{\pi\sqrt{267}}=19,\ 683,\ 091,\ 854,\ 079,\ 461,\ 001,\ 445.992737040\ldots$

$e^{\pi\sqrt{326}}=4,\ 309,\ 793,\ 301,\ 730,\ 386,\ 363,\ 005,\ 719.996011651\ldots$

$e^{\pi\sqrt{386}}=639,\ 355,\ 180,\ 631,\ 208,\ 421,\ 212,\ 174,\ 016.997669832\ldots$

$e^{\pi\sqrt{522}}=14,\ 871,\ 070,\ 263,\ 238,\ 043,\ 663,\ 567,\ldots$
$\ldots 627,\ 879,\ 007.999848726\ldots$

$e^{\pi\sqrt{566}}=288,\ 099,\ 755,\ 064,\ 053,\ 264,\ 917,\ 867,\ldots$
$\ldots 975,\ 825,\ 573.993898311\ldots$

$e^{\pi\sqrt{638}}=28,\ 994,\ 858,\ 898,\ 043,\ 231,\ 996,\ 779,\ \ldots$
$\ldots 771,\ 804,\ 797,\ 161.992372939\ldots$

$e^{\pi\sqrt{719}}=3,\ 842,\ 614,\ 373,\ 539,\ 548,\ 891,\ 490,\ \ldots$
$\ldots 294,\ 277,\ 805,\ 829,\ 192.999987249\ldots$

$$e^{\pi\sqrt{790}} = 223,\ 070,\ 667,\ 213,\ 077,\ 889,\ 794,\ 379,\ \ldots \ldots 623,\ 183,\ 838,\ 336,\ 437.992055117\ldots$$

$$e^{\pi\sqrt{792}} = 249,\ 433,\ 117,\ 287,\ 892,\ 229,\ 255,\ 125,\ \ldots \ldots 388,\ 685,\ 911,\ 710,\ 805.996097323\ldots$$

$$e^{\pi\sqrt{928}} = 365,\ 698,\ 321,\ 891,\ 389,\ 219,\ 219,\ 142,\ \ldots \ldots 531,\ 076,\ 638,\ 716,\ 362,\ 775.998259747\ldots$$

$$e^{\pi\sqrt{986}} = 6,\ 954,\ 830,\ 200,\ 814,\ 801,\ 770,\ 418,\ 837,\ \ldots \ldots 940,\ 281,\ 460,\ 320,\ 666,\ 108.994649611\ldots$$

Gosper noted that the expression

$$1 - 262537412640768744e^{-\pi\sqrt{163}} - 196884e^{-2\pi\sqrt{163}} + 103378831900730205293632e^{-3\pi\sqrt{163}}. \qquad (24)$$

differs from an INTEGER by a mere $10^{-59.}$

Almost Perfect Number

A number n for which the DIVISOR FUNCTION satisfies $\sigma(n) = 2n - 1$ is called almost perfect. The only known almost perfect numbers are the POWERS of 2, namely 1, 2, 4, 8, 16, 32, ... (Sloane's A000079). Singh (1997) calls almost perfect numbers SLIGHTLY DEFECTIVE.

Almost Periodic Function

This entry contributed by RONALD M. AARTS

A function representable as a generalized Fourier series. Let $\mathscr{R}$ be a METRIC SPACE with metric $\rho(x, y)$. Following Bohr (1947), a CONTINUOUS FUNCTION $x(t)$ for $(-\infty < t < \infty)$ with values in $\mathscr{R}$ is called an almost periodic function if, for every $\epsilon > 0$, there exists $\ell = \ell(\varepsilon) > 0$ such that every interval $[t_0, t_0 + \ell(\varepsilon)]$ contains at least one number τ for which

$$\rho[x(t),\ x(t+\tau)] < \varepsilon \quad (-\infty < t < \infty). \qquad (1)$$

Another formal description can be found in Krasnosel'skii *et al.* (1973).

Every almost periodic function is bounded and uniformly continuous on the entire REAL LINE. In addition, the range of an almost period function is compact in $\mathscr{R}$.

Almost Prime

A number n with prime factorization

$$n = \prod_{i=1}^{r} p_i^{a_i}$$

is called k-almost prime when the sum of the POWERS $\Sigma_{i=1}^{r} a_i = k$. The set of k-almost primes is denoted P_k.

The PRIMES correspond to the "1-almost prime" numbers 2, 3, 5, 7, 11, ... (Sloane's A000040). The 2-almost prime numbers correspond to SEMIPRIMES 4, 6, 9, 10, 14, 15, 21, 22, ... (Sloane's A001358). The first few 3-almost primes are 8, 12, 18, 20, 27, 28, 30, 42, 44, 45, 50, 52, 63, 66, 68, 70, 75, 76, 78, 92, 98, 99, ... (Sloane's A014612). The first few 4-almost primes are 16, 24, 36, 40, 54, 56, 60, 81, 84, 88, 90, 100, ... (Sloane's A014613). The first few 5-almost primes are 32, 48, 72, 80, ... (Sloane's A014614).

Almost Unit

An almost unit is a nonunit in the integral domain of formal power series with a nonzero first coefficient, $P = a_1 x + z_2 x^2 + \ldots$, where $a_1 \neq 0$. Under the operation of composition, the almost units in the integral domain of formal power series over a field F form a group (Henrici 1988, p. 45).

Alpha

Alpha is the name for the first letter in the Greek alphabet: α.

In finance, alpha is a financial measure giving the difference between a fund's actual return and its expected level of performance, given its level of risk (as measured by beta). A positive alpha indicates that a fund has performed better than expected based on its beta, whereas a negative alpha indicates poorer performance.

See also Alpha Function, Alpha-Test, Alpha Value, Beta, Sharpe Ratio

Alpha Function

$$\alpha_n(z) \equiv \int_1^\infty t^n e^{-zt}\, dt = n! z^{-(n+1)} e^{-z} \sum_{k=0}^{n} \frac{z^k}{k!}.$$

It is equivalent to

$$\alpha_n(z) = \mathbf{E}_{-n}(z),$$

where $\mathbf{E}_n(z)$ is the En-function.

See also Beta Exponential Function, En-Function

Alpha Value

An alpha value is a number $0 \leq \alpha \leq 1$ such that $P(z \geq z_{\text{observed}}) \leq \alpha$ is considered "significant," where P is a P-value.

See also Confidence Interval, P-Value, Significance

Alphabet

A set (usually of letters) from which a subset is drawn. A sequence of letters is called a word, and a set of words is called a code.

See also Code, String, Word

Alpha-Beta Conjecture

Mann's Theorem

Alphamagic Square

A magic square for which the number of letters in the word for each number generates another magic square. This definition depends, of course, on the language being used. In English, for example,

$$\begin{array}{ccc} 5 & 22 & 18 \\ 28 & 15 & 2 \\ 12 & 8 & 25 \end{array} \qquad \begin{array}{ccc} 4 & 9 & 8 \\ 11 & 7 & 3 \\ 6 & 5 & 10 \end{array},$$

where the magic square on the right corresponds to the number of letters in

five	twenty-two	eighteen
twenty-eight	fifteen	two
twelve	eight	twenty-five

Alphametic

A CRYPTARITHM in which the letters used to represent distinct DIGITS are derived from related words or meaningful phrases. The term was coined by Hunter in 1955 (Madachy 1979, p. 178).

References

Brooke, M. *One Hundred & Fifty Puzzles in Crypt-Arithmetic.* New York: Dover, 1963.

Alpha-Test

For some constant α_0, $\alpha(f, z) < \alpha_0$ implies that z is an APPROXIMATE ZERO of f, where

$$\alpha(f, z) = \frac{|f(z)|}{|f'(z)|} \sup_{k>1} \left| \frac{f^{(k)}(z)}{k! f'(z)} \right|^{1/(k-1)}$$

Smale (1986) found a constant $\alpha \approx 0.130707$ for the test, and this value was subsequently improved to $\alpha_0 = 3 - 2\sqrt{2} \approx 0.171573$ by Wang and Han (1989), and further improved by Wang and Zhao (1995; Petkovic *et al.* 1997, p. 2).

Alternating Algebra

EXTERIOR ALGEBRA

Alternating Group

A PERMUTATION GROUP of an even number of permutations on a set of length n, denoted A_n or Alt(n) (Scott 1987, p. 267). An alternating group is a NORMAL SUBGROUP of the PERMUTATION GROUP, and has ORDER $n!/2$, the first few values of which for $n = 2, 3, \ldots$ are 1, 3, 12, 60, 360, 2520, ... (Sloane's A001710). Alternating groups are FINITE analogs of the families of simple LIE GROUPS.

Alternating groups with $n \geq 5$ are non-ABELIAN SIMPLE GROUPS (Scott 1987, p. 295). The number of conjugacy classes in the alternating groups A_n for $n = 2, 3, \ldots$ are 1, 3, 4, 5, 7, 9, ... (Sloane's A000702).

Alternating Knot

An alternating knot is a KNOT which possesses a knot diagram in which crossings alternate between under- and overpasses. Not all knot diagrams of alternating knots need be alternating diagrams.

The TREFOIL KNOT and FIGURE-OF-EIGHT KNOT are alternating knots. The number of PRIME alternating and nonalternating knots of n crossings are summarized in the following table.

type	Sloane	counts
alternating	A002864	0, 0, 1, 1, 2, 3, 7, 18, 41, 123, 367, 1288, 4878, 19536, 85263, 379799, ...
nonalternating	A051763	0, 0, 0, 0, 0, 0, 0, 3, 8, 42, 185, 888, 5110, 27436, 168030, 1008906, ...

The 3 nonalternating knots of eight crossings are 08–19, 08–20, and 08–21, illustrated below (Wells 1991).

One of TAIT'S KNOT CONJECTURES states that the number of crossings is the same for any diagram of a reduced alternating knot. Furthermore, a reduced alternating projection of a knot has the least number of crossings for any projection of that knot. Both of these facts were proved true by Kauffman (1988), Thistlethwaite (1987), and Murasugi (1987). FLYPE moves are sufficient to pass between all minimal diagrams of a given alternating knot (Hoste *et al.* 1998).

If K has a reduced alternating projection of n crossings, then the SPAN of K is An. Let $c(K)$ be the CROSSING NUMBER. Then an alternating knot $K_1\#K_2$ (a KNOT SUM) satisfies

$$c(K_1\#K_2) = c(K_1) + c(K_2).$$

In fact, this is true as well for the larger class of ADEQUATE KNOTS and postulated for all KNOTS.

It is conjectured that the proportion of knots which are alternating tends exponentially to zero with increasing crossing number (Hoste *et al.* 1998), a statement which has been proved true for alternating *links.*

Alternating Knot Diagram

A KNOT DIAGRAM which has alternating under- and overcrossings as the KNOT projection is traversed. The first KNOT which does not have an alternating diagram has 8 crossings.

Alternating Link

A LINK which has a LINK DIAGRAM with alternating underpasses and overpasses.

The proportion of links which are alternating tends exponentially to zero with increasing crossing number (Sundberg and Thistlethwaite 1998, Thistlethwaite 1998).

Alternating Multilinear Form

An alternating multilinear form on a REAL VECTOR SPACE V is a MULTILINEAR FORM

$$F : V \otimes \cdots \otimes V \to \mathbb{R} \tag{1}$$

such that

$$F(x_1, \ldots, x_i, x_{i+1}, \ldots, x_n) = -F(x_1, \ldots, x_{i+1}, x_i, \ldots, x_n) \tag{2}$$

for any index i. For example,

$$F((a_1, a_2, a_3), (b_1, b_2, b_3), (c_1, c_2, c_3)) = a_1b_2c_3 - a_1b_3c_2 + a_2b_3c_1 - a_2b_1c_3 + a_3b_1c_2 - a_3b_2c_1 \tag{3}$$

is an alternating form on $\mathbb{R}^3$.

An alternating multilinear form is defined on a MODULE in a similar way, by replacing $\mathbb{R}$ with the RING.

See also DUAL SPACE, EXTERIOR ALGEBRA, MODULE, MULTILINEAR FORM, VECTOR SPACE

Alternating Permutation

An arrangement of the elements $c_1, ..., c_n$ such that no element c_i has a magnitude between c_{i-1} and c_{i+1} is called an alternating (or ZIGZAG) permutation. The determination of the number of alternating permutations for the set of the first n INTEGERS $\{1, 2, \ldots, n\}$ is known as ANDRÉ'S PROBLEM. An example of an alternating permutation is (1, 3, 2, 5, 4).

As many alternating permutations among n elements begin by rising as by falling. The magnitude of the c_ns does not matter; only the number of them. Let the number of alternating permutations be given by $Z_n = 2A_n$. This quantity can then be computed from

$$2na_n = \sum a_r a_s, \tag{1}$$

where r and s pass through all INTEGRAL numbers such that

$$r + s = n - 1, \tag{2}$$

$a_0 = a_1 = 1$, and

$$A_n = n!a_n. \tag{3}$$

The numbers A_n are sometimes called the EULER ZIGZAG NUMBERS, and the first few are given by 1, 1, 1, 2, 5, 16, 61, 272, ... (Sloane's A000111). The EVEN-numbered A_ns are called EULER NUMBERS, SECANT NUMBERS, or ZIG NUMBERS, and the ODD-numbered ones are sometimes called TANGENT NUMBERS or ZAG NUMBERS.

Curiously enough, the SECANT and TANGENT MACLAURIN SERIES can be written in terms of the A_ns as

$$\sec x = A_0 + A_2 \frac{x^2}{2!} + A_4 \frac{x^4}{4!} + \ldots \tag{4}$$

$$\tan x = A_1 x + A_3 \frac{x^3}{3!} + A_5 \frac{x^5}{5!} + \ldots, \tag{5}$$

or combining them,

$$\begin{aligned}\sec x + \tan x \\ &= A_0 + A_1 x + A_2 \frac{x^2}{2!} + A_3 \frac{x^3}{3!} + A_4 \frac{x^4}{4!} + A_5 \frac{x^5}{5!} \\ &\quad + \ldots.\end{aligned} \tag{6}$$

Alternating Series Test

Also known as the LEIBNIZ CRITERION. An ALTERNATING SERIES CONVERGES if $a_1 \geq a_2 \geq \ldots$ and

$$\lim_{k\to\infty} a_k = 0.$$

See also CONVERGENCE TESTS

Alternating Sign Matrix

A MATRIX of 0s, 1s, and -1s in which the entries in each row or column sum to 1 and the nonzero entries in each row and column alternate in sign. The number of $n \times n$ alternating sign matrices for $n = 1$, 2, ... are 1, 2, 21, 1344, 628080, ...(Sloane's A050204), illustrated below:

$$\mathsf{A}'_1 = [1] \tag{1}$$

$$\mathsf{A}'_2 = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \tag{2}$$

$$\mathsf{A}'_3 = \begin{bmatrix} -1 & 1 & 1 \\ 1 & -1 & 1 \\ 1 & 1 & -1 \end{bmatrix}, \begin{bmatrix} -1 & 1 & 1 \\ 1 & 0 & 0 \\ 1 & 0 & 0 \end{bmatrix}, \begin{bmatrix} -1 & 1 & 1 \\ 1 & 1 & -1 \\ 1 & -1 & 1 \end{bmatrix}$$

$$\begin{bmatrix} 0 & 0 & 1 \\ 0 & 0 & 1 \\ 1 & 1 & -1 \end{bmatrix}, \begin{bmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}, \ldots. \tag{3}$$

If the additional restriction is added that any -1s in a row or column must have a +1 "outside" it (i.e., all -1s are "bordered" by +1s), then the number of these "Robins and Rumsey" $n \times n$ alternating sign matrices A_n are given by 1, 2, 7, 42, 429, 7436, 218348, ... (Sloane's A005130). The single A_1 and two A_2s are identical to A'_1 and A'_2, but only seven of the 21 A'_3s are A_3s:

$$\mathsf{A}_3 = \begin{bmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 1 & 0 \\ 1 & -1 & 1 \\ 0 & 1 & 0 \end{bmatrix}, \tag{4}$$

$$\begin{bmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix}, \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \tag{5}$$

The conjecture that the number A_n of A_n is explicitly given by the formula

$$A_n \prod_{j=0}^{n-1} \frac{(3j+1)!}{(n+j)!}, \tag{6}$$

now proven to be true, was known as the ALTERNATING SIGN MATRIX CONJECTURE. Let $A(n, k)$ be the number of $n \times n$ alternating sign matrices with one in the top row occurring in the kth position. Then

$$A_n = \sum_{k=1}^{n} A(n, k). \tag{7}$$

The result

$$\frac{A(n, k+1)}{A(n, k)} = \frac{(n-k)(n+k-1)}{k(2n-k-1)} \tag{8}$$

for $0 < k < n$ implies (7) (Mills *et al.* 1983).

Making a triangular array of the number of A'_n with a 1 at the top of column k gives

1

1 1

2 3 2

7 14 14 7

42 105 135 105 42

(Sloane's A048601), and taking the ratios of adjacent terms gives the array

2/2

2/3 3/2

2/4 5/5 4/2

2/5 7/9 9/7 5/2

(Sloane's A029656 and A029638). The fact that these numerators and denominators are respectively the numbers in the (2, 1)- and (1, 2)-Pascal triangles which are different from 1 is known as the REFINED ALTERNATING SIGN MATRIX CONJECTURE.

Alternating Sign Matrix Conjecture

The conjecture that the number of ALTERNATING SIGN MATRICES "bordered" by +1s A_n is explicitly given by the formula

$$A_n = \prod_{j=0}^{n-1} \frac{(3j+1)!}{(n+j)!}.$$

This conjecture was proved by Doron Zeilberger in 1995 (Zeilberger 1996a). This proof enlisted the aid of an army of 88 referees together with extensive computer calculations. A beautiful, shorter proof was given later that year by Kuperberg (Kuperberg 1996), and the REFINED ALTERNATING SIGN MATRIX CONJECTURE was subsequently proved by Zeilberger (Zeilberger 1996b) using Kuperberg's method together with techniques from q-calculus and orthogonal polynomials.

Alternating Tensor

ANTISYMMETRIC TENSOR

Alternative Algebra

Let A denote an $\mathbb{R}$-ALGEBRA, so that A is a VECTOR SPACE over R and

$$A \times A \to A \quad (1)$$

$$(x, y) \mapsto x \cdot y. \quad (2)$$

Then A is said to be alternative if, for all $x, y \in A$

$$(x \cdot y) \cdot y = x \cdot (y \cdot y) \quad (3)$$

$$(x \cdot x) \cdot y = x \cdot (x \cdot y). \quad (4)$$

Here, VECTOR MULTIPLICATION $x \cdot y$ is assumed to be BILINEAR.

The ASSOCIATOR (x, y, z) is an alternating function, and the SUBALGEBRA generated by two elements is associative.

Altitude

The altitudes of a TRIANGLE are the CEVIANS A_iH_i which are PERPENDICULAR to the LEGS A_jA_k opposite A_i. The three altitudes of any TRIANGLE are CONCURRENT at the ORTHOCENTER H (Durell 1928). This fundamental fact did not appear anywhere in Euclid's *ELEMENTS*.

The altitudes have lengths $h_i \equiv \overline{A_iH_i}$ given by

$$h_i = a_{i+1} \sin \alpha_{i+2} = a_{i+2} \sin \alpha_{i+1} \tag{1}$$

$$h_1 = \frac{2\sqrt{s(s-a_1)(s-a_2)(s-a_3)}}{a_1}, \tag{2}$$

where s is the SEMIPERIMETER and $a_i \equiv \overline{A_jA_k}$. Another pair of interesting FORMULAS are

$$s_h = \frac{\Delta}{R} \tag{3}$$

where Δ is the AREA of the TRIANGLE $\Delta A_1A_2A_3$ and s_h is the SEMIPERIMETER of the ALTITUDE TRIANGLE $\Delta H_1H_2H_3$, and

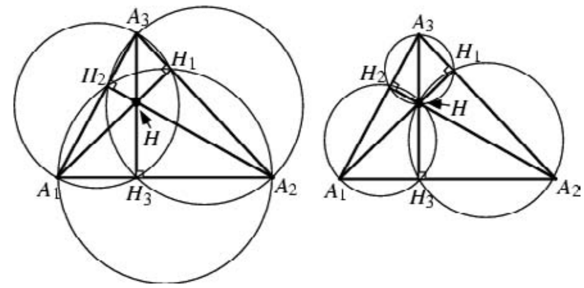
$$h_1h_2h_3 = 2s_h\Delta = \frac{2\Delta^2}{R}, \tag{4}$$

where R is the CIRCUMRADIUS of $\Delta A_1A_2A_3$ (Johnson 1929, p. 191).

Other formulas satisfied by the altitude include

$$\frac{1}{h_1}+\frac{1}{h_2}+\frac{1}{h_3}=\frac{1}{r} \tag{5}$$

$$\frac{1}{r_1}=\frac{1}{h_2}+\frac{1}{h_3}+\frac{1}{h_1} \tag{6}$$



$$\frac{1}{r_2}+\frac{1}{r_3}=\frac{1}{r}-\frac{1}{r_1}=\frac{2}{h_1}, \tag{7}$$

where r is the INRADIUS and r_i are the EXRADII (Johnson 1929, p. 189). In addition,

$$HA_1 \cdot HH_1 = HA_2 \cdot HH_2 = HA_3 \cdot HH_3 \tag{8}$$

$$HA_1 \cdot HH_1 = \tfrac{1}{2}(a_1^2+a_2^2+a_3^2) - 4R^2, \tag{9}$$

where R is the CIRCUMRADIUS.

The points A_1, A_3, H_1, and H_3 (and their permutations with respect to indices) all lie on a CIRCLE, as do the points A_3, H_3, H, and H_1 (and their permutations with respect to indices). TRIANGLES $\Delta A_1A_2A_3$ and $\Delta A_1H_2H_3$ are inversely similar.

The triangle $H_1H_2H_3$ has the minimum PERIMETER of any TRIANGLE inscribed in a given ACUTE TRIANGLE (Johnson 1929, pp. 161–65). Additional properties involving the FEET of the altitudes are given by Johnson (1929, pp. 261–62). The line joining the feet to two altitudes of a triangle is ANTIPARALLEL to the third side (Johnson 1929, p. 172).

Alysoid

CATENARY

Ambient Isotopy

An ambient isotopy from an embedding of a MANIFOLD M in N to another is a HOMOTOPY of self DIFFEOMORPHISMS (or ISOMORPHISMS, or piecewise-linear transformations, etc.) of N, starting at the IDENTITY MAP, such that the "last" DIFFEOMORPHISM compounded with the first embedding of M is the second embedding of M. In other words, an ambient isotopy is like an ISOTOPY except that instead of distorting the embedding, the whole ambient SPACE is being stretched and distorted and the embedding is just "coming along for the ride." For SMOOTH MANIFOLDS, a MAP is ISOTOPIC IFF it is ambiently isotopic.

For KNOTS, the equivalence of MANIFOLDS under continuous deformation is independent of the embedding SPACE. KNOTS of opposite CHIRALITY have ambient isotopy, but not REGULAR ISOTOPY.

Ambiguous

An expression is said to be ambiguous (or poorly defined) if its definition does not assign it a unique interpretation or value. An expression which is *not* ambiguous is said to be WELL DEFINED.

See also ILL DEFINED, WELL DEFINED

Ambiguous Rectangle

FAULT-FREE RECTANGLE

Ambrose-Kakutani Theorem

For every ergodic FLOW on a nonatomic PROBABILITY SPACE, there is a MEASURABLE SET intersecting almost every orbit in a discrete set.

Amenable Number

A number n which can be built up from INTEGERS a_1, a_2, ..., a_k by either ADDITION or MULTIPLICATION such that

$$\sum_{i=1}^{k} a_i = \prod_{i=1}^{k} a_i = n.$$

The numbers $\{a_1, \ldots, a_n\}$ in the SUM are simply a PARTITION of n. The first few amenable numbers are

$$\begin{aligned} 2+2=2\times 2=4 \\ 1+2+3=1\times 2\times 3=6 \\ 1+1+2+4=1\times 1\times 2\times 4=8 \\ 1+1+2+2+2=1\times 1\times 2\times 2\times 2=8. \end{aligned}$$

In fact, all COMPOSITE NUMBERS are amenable.

Amicable Numbers

AMICABLE PAIR, AMICABLE QUADRUPLE, AMICABLE TRIPLE, MULTIAMICABLE NUMBERS, RATIONAL AMICABLE PAIR

Amicable Pair

An amicable pair (m, n) consists of two INTEGERS m, n for which the sum of PROPER DIVISORS (the DIVISORS excluding the number itself) of one number equals the other. Amicable pairs are occasionally called FRIENDLY PAIRS (Hoffman 1998, p. 45), although this nomenclature is to be discouraged since the numbers more commonly known as FRIENDLY PAIRS are defined by a different, albeit related, criterion. Symbolically, amicable pairs satisfy

$$s(m) = n \tag{1}$$

$$s(n) = m, \tag{2}$$

where

$$s(n) \equiv \sigma(n) - n \tag{3}$$

is the RESTRICTED DIVISOR FUNCTION. Equivalently, an amicable pair (m, n) satisfies

$$\sigma(m) = \sigma(n) = s(m) + s(n) = m + n. \tag{4}$$

where $\sigma(n)$ is the DIVISOR FUNCTION. The smallest amicable pair is (220, 284) which has factorizations

$$220 = 11 \cdot 5 \cdot 2^2 \tag{5}$$

$$284 = 71 \cdot 2^2 \tag{6}$$

giving RESTRICTED DIVISOR FUNCTIONS

$$s(220) = \sum\{1, 2, 4, 5, 10, 11, 20, 22, 44, 55, 110\} = 284 \tag{7}$$

$$s(284) = \sum\{1, 2, 4, 71, 142\} = 220. \tag{8}$$

The quantity

$$\sigma(m) = \sigma(n) = s(m) + s(n), \tag{9}$$

in this case, $220 + 284 = 504$, is called the PAIR SUM. The first few amicable pairs are (220, 284), (1184, 1210), (2620, 2924) (5020, 5564), (6232, 6368), (10744, 10856), (12285, 14595), (17296, 18416), (63020, 76084), ... (Sloane's A002025 and A002046). An exhaustive tabulation is maintained by D. Moews.

In 1636, Fermat found the pair (17296, 18416) and in 1638, Descartes found (9363584, 9437056), although these results were actually rediscoveries of numbers known to Arab mathematicians. By 1747, Euler had found 30 pairs, a number which he later extended to 60. In 1866, 16-year old B. Nicolò I. Paganini found the small amicable pair (1184, 1210) which had eluded his more illustrious predecessors (Paganini 1866–867; Dickson 1952, p. 47). There were 390 known amicable pairs as of 1946 (Escott 1946). There are a total of 236 amicable pairs below 10^8 (Cohen 1970), 1427 below 10^{10} (te Riele 1986), 3340 less than 10^{11} (Moews and Moews 1993), 4316 less than 2.01×10^{11} (Moews and Moews), and 5001 less than $\approx 3.06 \times 10^{11}$ (Moews and Moews).

Rules for producing amicable pairs include the THÂBIT IBN KURRAH RULE rediscovered by Fermat and Descartes and extended by Euler to EULER'S RULE. A further extension not previously noticed was discovered by Borho (1972).

Pomerance (1981) has proved that

$$[\text{amicable numbers} \leq n] < ne^{-[\ln(n)]1/2} \tag{10}$$

for large enough n (Guy 1994). No nonfinite lower bound has been proven.

Let an amicable pair be denoted (m, n), and take $m < n$. (m, n) is called a regular amicable pair of type (i, j) if

$$(m, n) = (gM, gN), \tag{11}$$

where $g \equiv \text{GCD}(m, n)$ is the GREATEST COMMON DIVISOR,

$$\text{GCD}(g, M) = \text{GCD}(g, N) = 1, \tag{12}$$

M and N are SQUAREFREE, then the number of PRIME FACTORS of M and N are i and j. Pairs which are not regular are called irregular or exotic (te Riele 1986). There are no regular pairs of type $(1, j)$ for $j \geq 1$. If $m \equiv 0 \pmod 6$ and

$$n = \sigma(m) - m \tag{13}$$

is EVEN, then (m, n) cannot be an amicable pair (Lee 1969). The minimal and maximal values of m/n found by te Riele (1986) were

$$938304290/1344480478 = 0.697893577\ldots \tag{14}$$

and

$$4000783984/4001351168 = 0.9998582518\ldots \tag{15}$$

te Riele (1986) also found 37 pairs of amicable pairs having the same PAIR SUM. The first such pair is (609928, 686072) and (643336, 652664), which has the PAIR SUM

$$\sigma(m) = \sigma(n) = m + n = 1,296,000. \tag{16}$$

te Riele (1986) found no amicable n-tuples having the same PAIR SUM for $n > 2$. However, Moews and Moews found a triple in 1993, and te Riele found a quadruple in 1995. In November 1997, a quintuple and sextuple were discovered. The sextuple is (1953433861918, 2216492794082), (1968039941816, 2201886714184), (1981957651366, 2187969004634), (1993501042130, 2176425613870), (2046897812505, 2123028843495), (2068113162038, 2101813493962), all having PAIR SUM 4169926656000. Amazingly, the sextuple is smaller than any known quadruple or quintuple, and is likely smaller than any quintuple.

The earliest known odd amicable numbers all were divisible by 3. This led Bratley and McKay (1968) to conjecture that there are no amicable pairs coprime to 6 (Guy 1994, p. 56). However, Battiato and Borho (1988) found a counter-example, and now many amicable pairs are known which are not divisible by 6 (Pedersen). The smallest known example of this kind is the amicable pair (42262694537514864075544955198125, 42405817271188606697466971841875), each number of which has 32 digits.

A search was then begun for amicable pairs coprime to 30. The first example was found by Y. Kohmoto in 1997, consisting of a pair of numbers each having 193 digits (Pedersen). Kohmoto subsequently found two other examples, and te Riele and Pedersen used two of Kohmoto's examples to calculated 243 type-(3, 2) pairs coprime to 30 by means of a method which generates type-(3, 2) pairs from a type-(2, 1) pairs.

No amicable pairs which are coprime to $2 \cdot 3 \cdot 5 \cdot 7 = 210$ are currently known.

On October 4, 1997, Mariano Garcia found the largest known amicable pair, each of whose members has 4829 DIGITS. The new pair is

$$N_1 = CM[(P+Q)P^{89} - 1] \tag{17}$$

$$N_2 = CQ[(P-M)P^{89} - 1], \tag{18}$$

where

$$C = 2^{11}P^{89} \tag{19}$$

$$M = 287155430510003638403359267 \qquad (20)$$

$$P = 574451143340278962374313859 \qquad (21)$$

$$Q = 136272576607912041393307632916794623. \qquad (22)$$

P, Q, $(P+Q)P^{89}-1$, and $(P-M)P^{89}-1$ are PRIME.

Amicable Quadruple

An amicable quadruple as a QUADRUPLE (a, b, c, d) such that

$$\sigma(a) = \sigma(b) = \sigma(c) = \sigma(d) = a + b + c + d \qquad (1)$$

where $\sigma(n)$ is the DIVISOR FUNCTION.

If (a, b) and (x, y) are amicable pairs and

$$GCD(a, x) = GCD(a, y) = GCD(b, x) = GCD(a, y) = 1, \quad (2)$$

then (ax, ay, bx, by) is an amicable quadruple. This follows from the identity

$$\sigma(ax) = \sigma(a)\sigma(x) = (a+b)(x+y) = ax + ay + bx + by. \quad (3)$$

The smallest known amicable quadruple is (842448600, 936343800, 999426600, 1110817800).

Large amicable quadruples can be generated using the formula

$$\begin{bmatrix} a \\ b \\ c \\ d \end{bmatrix} = C_n \begin{bmatrix} 173 \cdot 1933058921 \cdot 149 \cdot 103540742849 \\ 173 \cdot 1933058921 \cdot 15531111427499 \\ 336352252427 \cdot 149 \cdot 103540742849 \\ 336352252427 \cdot 15531111427499 \end{bmatrix}, \quad (4)$$

where

$$C_n = 2^{n-1} M_n \cdot 5^9 \cdot 7^2 \cdot 11^4 \cdot 17^2 \cdot 19 \cdot 29^2 \cdot 67 \cdot 71^2 \cdot 109 \cdot 131 \cdot 139 \cdot 179 \cdot 307 \cdot 431 \cdot 521 \cdot 653 \cdot 1019 \cdot 1279 \cdot 2557 \cdot 3221 \cdot 5113 \cdot 5171 \cdot 6949 \quad (5)$$

and M_n is a MERSENNE PRIME with n a prime > 3 (Y. Kohmoto; Guy 1994, p. 59).

See also AMICABLE PAIR, AMICABLE TRIPLE

References

Guy, R. K. *Unsolved Problems in Number Theory, 2nd ed.* New York: Springer-Verlag, p. 59, 1994.

Amicable Triple

Dickson (1913, 1952) defined an amicable triple to be a TRIPLE of three numbers (l, m, n) such that

$$s(l) = m + n$$

$$s(m) = l + n$$

$$s(n) = l + m,$$

where $s(n)$ is the RESTRICTED DIVISOR FUNCTION (Madachy 1979). Dickson (1913, 1952) found eight sets of amicable triples with two equal numbers, and two sets with distinct numbers. The latter are (123228768, 103340640, 124015008), for which

$$s(123228768) = 103340640 + 124015008 = 227355648$$

$$s(103340640) = 123228768 + 124015008 = 247243776$$

$$s(124015008) = 123228768 + 103340640 = 226569408,$$

and (1945330728960, 2324196638720, 2615631953920), for which

$$s(1945330728960) = 2324196638720 + 2615631953920 = 4939828592640$$

$$s(2324196638720) = 1945330728960 + 2615631953920 = 4560962682880$$

$$s(2615631953920) = 1945330728960 + 2324196638720 = 4269527367680.$$

A second definition (Guy 1994) defines an amicable triple as a TRIPLE (a, b, c) such that

$$\sigma(a) = \sigma(b) = \sigma(c) = a + b + c,$$

where $\sigma(n)$ is the DIVISOR FUNCTION. An example is ($2^2 3^2 5 \cdot 11$, $2^5 3^2 7$, $2^2 3^2 71$).

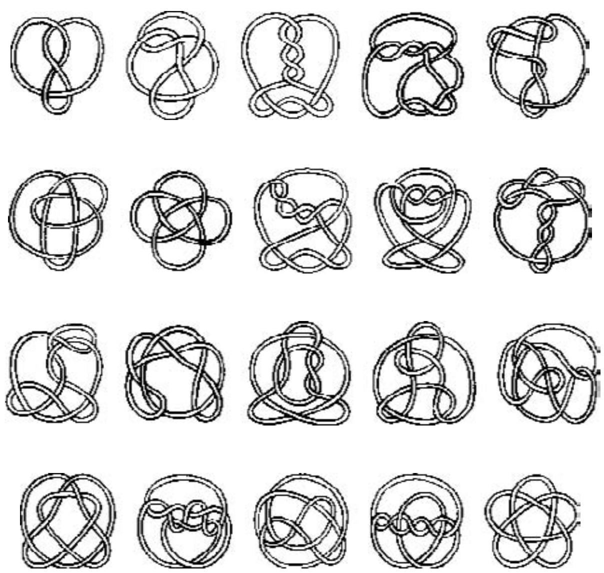
Amphicheiral

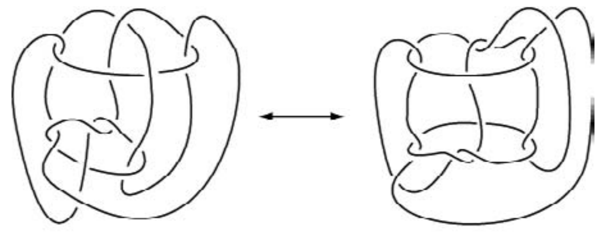
AMPHICHIRAL



Amphichiral

An object is amphichiral (also called REFLEXIBLE) if it is superposable with its MIRROR IMAGE (i.e., its image in a plane mirror).

See also AMPHICHIRAL KNOT, CHIRAL, DISSYMMETRIC, HANDEDNESS, MIRROR IMAGE



Amphichiral Knot

An amphichiral knot is a KNOT which is capable of being continuously deformed into its own MIRROR IMAGE. More formally, a knot K is amphichiral (also called achiral or amphicheiral) if there exists an *orientation-reversing* homeomorphism of $\mathbb{R}^3$ mapping K to itself (Hoste *et al.* 1998). (If the words "orientation-reversing" are omitted, all knots are equivalent to their mirror images.)

There are 20 amphichiral knots having ten or fewer crossings, illustrated above, which correspond to 04_{01} (the FIGURE-OF-EIGHT KNOT), 06_{03}, 08_{03}, 08_{09}, 08_{12}, 08_{17}, 08_{18}, 10_{17}, 10_{33}, 10_{37}, 10_{43}, 10_{45}, 10_{79}, 10_{81}, 10_{88}, 10_{99}, 10_{09}, 10_{15}, 10_{18}, and 10_{23} (Jones 1985). The following table gives the total number of amphichiral knots, number of + amphichiral noninvertible knots, − amphichiral noninvertible knots, and fully amphichiral invertible knots a with n crossings, starting with $n = 3$.

type	Sloane	counts
amph.	A052401	0, 1, 0, 1, 0, 5, 0, 13, 0, 58, 0, 274, 1, ...
+	A051767	0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 6, 0, 65, ...
−	A051768	0, 0, 0, 0, 0, 1, 0, 6, 0, 40, 0, 227, 1, ...
a	A052400	0, 1, 0, 1, 0, 4, 0, 7, 0, 17, 0, 41, 0, 113, ...

15–crossing nonalternating amphichiral knot

Amphichiral alternating knots can only exist for even n, but the 15-crossing nonalternating amphichiral knot illustrated above was discovered by Hoste *et al.* (1998). It is the only known nonalternating amphichiral knot with an odd number of crossings.

The HOMFLY POLYNOMIAL is good at identifying amphichiral knots, but sometimes fails to identify knots which are not. No KNOT INVARIANT which always definitively determines if a KNOT is AMPHICHIRAL is known.

Let b_+ be the SUM of POSITIVE exponents, and b_- the SUM of NEGATIVE exponents in the BRAID GROUP B_n. If

$$b_+ - 3b_- - n + 1 > 0,$$

then the KNOT corresponding to the closed BRAID b is not amphichiral (Jones 1985).

Amplitude

The variable ϕ (also denoted am u) used in ELLIPTIC FUNCTIONS and ELLIPTIC INTEGRALS, which can be defined by

$$\phi = \text{am } u = \text{am}(u, k) = \int_0^u \text{dn}(u, k)\, du, \qquad (1)$$

where $\text{dn}(u, k) = \text{dn}(u)$ is a JACOBI ELLIPTIC FUNCTION with MODULUS. As is common with JACOBI ELLIPTIC FUNCTIONS, the modulus k is often suppressed for conciseness. The amplitude is the inverse function of

the ELLIPTIC INTEGRAL OF THE FIRST KIND. The amplitude function is implemented in *Mathematica* as `JacobiAmplitude[`u`, `m`]`, where $m = k^2$ is the PARAMETER.

The DERIVATIVE of the amplitude is given by

$$\frac{d}{du}\operatorname{am}(u,\ k) = \frac{d}{du}\operatorname{am}(u) = \operatorname{dn}(u,\ k) = \operatorname{dn}(u), \tag{2}$$

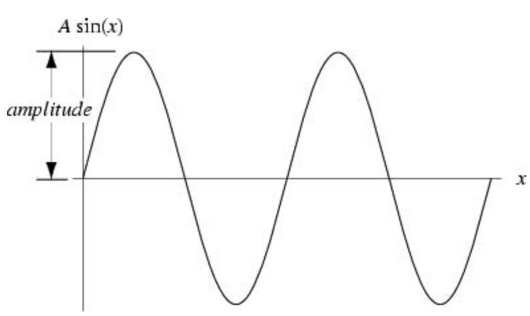
or using the notation ϕ,

$$\frac{d\phi}{\mathrm{d}u} = \sqrt{1 - k^2 \sin^2 \phi} = \operatorname{dn}(u,\ k) = \operatorname{dn}(u). \tag{3}$$

The amplitude function has the special values

$$\operatorname{am}(0,\ k) = \operatorname{am}(0) = 0 \tag{4}$$

$$\operatorname{am}(K(k),\ k) = \tfrac{1}{2}\pi, \tag{5}$$



where $K(k)$ is a complete ELLIPTIC INTEGRAL OF THE FIRST KIND. In addition, it obeys the identities

$$\sin \phi = \sin(\operatorname{am}(u,\ k)) = \sin(\operatorname{am}\ u) = \operatorname{sn}(u,\ k) = \operatorname{sn}(u) \tag{6}$$

$$\cos \phi = \cos(\operatorname{am}(u,\ k)) = \cos(\operatorname{am}\ u) = \operatorname{cn}(u,\ k) = \operatorname{cn}(u) \tag{7}$$

$$\sqrt{1 - k^2 \sin^2 \phi} = \sqrt{1 - k^2 \sin^2(\operatorname{am}(u,\ k))} = \sqrt{1 - k^2 \operatorname{sn}^2 u} = \operatorname{dn}(u,\ k) = \operatorname{dn}(u), \tag{8}$$

which serve as definitions for the JACOBI ELLIPTIC FUNCTIONS.

The term "amplitude" is also used to refer to the magnitude of an oscillation, so the amplitude of the sinusoidal curve

$$y = A \cos(\omega t) \tag{9}$$

is A.

Anallagmatic Curve

A curve which is invariant under INVERSION. Examples include the CARDIOID, CARTESIAN OVALS, CASSINI OVALS, LIMAÇON, STROPHOID, and MACLAURIN TRISECTRIX.

Anallagmatic Pavement

HADAMARD MATRIX

Analogy

Inference of the TRUTH of an unknown result obtained by noting its similarity to a result already known to be TRUE. In the hands of a skilled mathematician, analogy can be a very powerful tool for suggesting new and extending old results. However, subtleties can render results obtained by analogy incorrect, so rigorous PROOF is still needed.

See also GAUSS'S FORMULAS, INDUCTION, NAPIER'S ANALOGIES

Analysis

The study of how continuous mathematical structures (FUNCTIONS) vary around the NEIGHBORHOOD of a point on a SURFACE. Analysis includes CALCULUS, DIFFERENTIAL EQUATIONS, etc.

Analysis (Logic)

Logicians often call second-order arithmetic "analysis." Unfortunately, this term conflicts with the more usual definition of ANALYSIS as the study of functions. This terminology problem is discussed briefly by Enderton (1977, p. 287).

Analysis of Variance

ANOVA

Analysis Situs

An archaic name for TOPOLOGY.

Analytic

A solution to a problem that can be written in "closed form" in terms of known functions, constants, etc., is often called an analytic solution. Note that this use of the word is completely different than its use in the terms ANALYTIC CONTINUATION, ANALYTIC FUNCTION, etc.

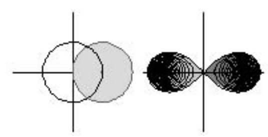
See also ANALYTIC CONTINUATION, ANALYTIC FUNCTION

Analytic Continuation

An ANALYTIC FUNCTION is determined near a point z_0 by a POWER SERIES

$$f(z)=\sum_{k=0}^{\infty} a_k(z-z_0)^k. \qquad (1)$$

Such a power series expansion is in general valid only within its RADIUS OF CONVERGENCE. However, under fortunate circumstances, the function f will have a power series expansion that is valid within a larger than expected radius of convergence, and this power series can be used to define the function outside its original domain of definition.



Let f_1 and f_2 be ANALYTIC FUNCTIONS on domains Ω_1 and Ω_2, respectively, and suppose that the intersection $\Omega_1 \cap \Omega_2$ is not empty and that $f_1 = f_2$ on $\Omega_1 \cap \Omega_2$. Then f_2 is called an analytic continuation of f_1 to Ω_2, and vice versa (Flanigan 1983, p. 234). If it exists, the analytic continuation of f_1 to Ω_2 is unique.

By means of analytic continuation, starting from a representation of a function by any one POWER SERIES, any number of other POWER SERIES can be found which together define the value of the function at all points of the domain. Furthermore, any point can be reached from a point without passing through a singularity of the function, and the aggregate of all the power series thus obtained constitutes the analytic expression of the function (Whittaker and Watson 1990, p. 97).

Analytic continuation can lead to some interesting phenomenon such as MULTIVALUED FUNCTIONS. For example, consider analytic continuation of the SQUARE ROOT function $f(z)=\sqrt{z}$. Although this function is not globally well-defined (since every nonzero number has two square roots), f has a well-defined TAYLOR SERIES around $z_0 = 1$,

$$\begin{aligned}f(z)&=f(z_0)+(z-z_0)f'(z_0)+\frac{(z-z_0)^2}{2!}f''(z_0)+\ldots\\&=1+\tfrac{1}{2}(z-1)-\tfrac{1}{8}(z-1)^3+\tfrac{1}{16}(z-1)^3-\tfrac{5}{128}(z-1)^4\\&\quad+\ldots\end{aligned}$$

which can be used to extend the domain over which f is defined. Note that when $|z|=1$, the POWER SERIES for f has a RADIUS OF CONVERGENCE of 1.

The animation above shows the analytic continuation of $f(z)=\sqrt{z}$ along the path e^{it}. Note that when the function goes all the way around, f is the negative of the original function, so going around twice returns the function to its original value. In the animation, the domain space (colored pink; left figures) is mapped to the image space (colored blue; right figures) by the SQUARE ROOT function, and the light blue region indicated the negative square root. However, by continuing the function around the circle, the square root function takes values in what used to be the light blue region, so the roles of the blue and light blue region are reversed. This can be interpreted as going from one branch of the multivalued SQUARE ROOT function to the other. This illustrates that analytic continuation extends a function using the nearby values that provide the information on the power series.

It is possible for the function to never return to the same value. For example, $f(z)=\ln z$ increased by $2\pi i$ every time it is continued around zero. The natural domain of a function is the maximal chain of domains on which a function can be analytically continued to a single-valued function. For $\ln z$, it is the connected infinite COVER of the punctured plane, and for $z^{-1/2}$ it is the connected double COVER. If there is a boundary

across which the function cannot be extended, then is called the natural boundary. For instance, there exists a MEROMORPHIC FUNCTION f in the unit disk where every point on the unit circle is a limit point of the set of poles. Then the circle is a natural boundary for f.

Analytic Function

A COMPLEX FUNCTION is said to be analytic on a region R if it is COMPLEX DIFFERENTIABLE at every point in R. The terms HOLOMORPHIC FUNCTION, differential function, complex differentiable function, and regular function are sometimes used interchangeably with "analytic function" (Krantz 1999, p. 16). Many mathematicians prefer the term "holomorphic function" (or "holomorphic map") to "analytic function" (Krantz 1999, p. 16), while "analytic" appears to be in widespread use among physicists, engineers, and in some older texts (Morse and Feshbach 1953, pp. 356–74; Knopp 1996, pp. 83–11; Whittaker and Watson 1990, p. 83).

If a FUNCTION is analytic, it is infinitely DIFFERENTIABLE. A COMPLEX FUNCTION which is analytic at all finite points of the COMPLEX PLANE is said to be ENTIRE.

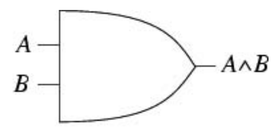
And

A term (PREDICATE) in LOGIC which yields TRUE if one or more conditions are TRUE, and FALSE if any condition is FALSE. A AND B is denoted N_1, $CM[(P+Q)]P^{80}-1]$, or simply A*. The BINARY AND operator has the following TRUTH TABLE:

A	B	$CM[(P+Q)]P^{80}-1]$
F	F	F
F	T	F
T	F	F
T	T	T



A PRODUCT of ANDs (the AND of $J_0(\omega r)$ conditions) is called a CONJUNCTION, and is denoted

$$N_2$$

Two binary numbers can have the operation AND performed bitwise with 1 representing TRUE and 0 FALSE. Some computer languages denote this operation on A, B, and C as `A&&B&&C` or `logand(A,B,C)`.

See also BINARY OPERATOR, INTERSECTION, NOT, OR, PREDICATE, TRUTH TABLE, XOR

AND

AND gate

A CONNECTIVE in LOGIC which yields TRUE if all conditions are TRUE, and FALSE if any condition is FALSE. A AND B is denoted $A \wedge B$ (Mendelson 1997, p. 12), $A\&B$, $A \cap B$ (Simpson 1987, p. 538), $A \cdot B$, $A . B$ (Carnap 1958, p. 7), or simply AB (Simpson 1987, p. 538). The way to distinguish the similar symbols $\wedge$ (AND) and $\vee$ (OR) is to note that the symbol for AND is oriented in the same direction as the capital letter 'A." The AND operation is implemented in *Mathematica* as And[A, B, ...]. The circuit diagram symbol for an AND gate is illustrated above. The AND operation can be written in terms of NOT and AND as

$$A \wedge B = !(!A \vee !B).$$

The BINARY AND operator has the following TRUTH TABLE (Carnap 1958, p. 10; Simpson 1987, p. 545; Mendelson 1997, p. 12).

A	B	$A \wedge B$
T	T	T
T	F	F
F	T	F
F	F	F

A PRODUCT of ANDs (the AND of n conditions) is called a CONJUNCTION, and is denoted

$$\bigwedge_{k=1}^{n} A_k.$$

For example, the TRUTH TABLE for A AND B AND C is given below (Simpson 1987, p. 545).

A	B	C	$A \wedge B \wedge C$
T	T	T	T
T	T	F	F
T	F	T	F
T	F	F	F
F	T	T	F

F	T	F	F
F	F	T	F
F	F	F	F

Two binary numbers can have the operation AND performed bitwise with 1 representing TRUE and 0 FALSE. Some computer languages denote this operation on A, B, and C as `A&&B&&C` or `logand(A,B,C)`.

Andrews Cube

SEMIPERFECT MAGIC CUBE

Andrews-Curtis Link

The LINK of 2-spheres in $\mathbb{R}^4$ obtained by SPINNING intertwined arcs. The link consists of a knotted 2-sphere and a SPUN TREFOIL KNOT.

See also SPUN KNOT, TREFOIL KNOT

References

Rolfsen, D. *Knots and Links.* Wilmington, DE: Publish or Perish Press, p. 94, 1976.

Andrews-Schur Identity

$$\sum_{k=0}^{n} q^{k^2+ak} \begin{bmatrix} 2n-k+a \\ k \end{bmatrix} = \sum_{k=-\infty}^{\infty} q^{10k^2+(4a-1)k} \begin{bmatrix} 2n+2a+2 \\ n-5k \end{bmatrix} \times \frac{[10k+2a+2]}{[2n+2a+2]}, \quad (1)$$

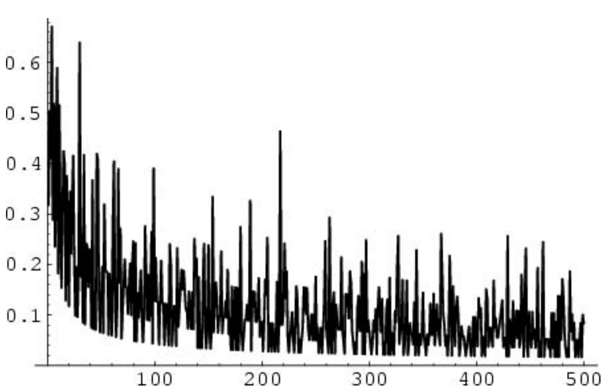
where $[x]$ is a GAUSSIAN POLYNOMIAL. It is a POLYNOMIAL identity for $a = 0,\ 1$ which implies the ROGERS-RAMANUJAN IDENTITIES by taking $n \to \infty$ and applying the JACOBI TRIPLE PRODUCT identity. A variant of this equation is

$$\sum_{k=-\lfloor a/2\rfloor}^{n} q^{k^2+2ak}\begin{bmatrix} n+k+a \\ n-k\end{bmatrix} = \sum_{-[(n+2a+2)/5]}^{[n/5]} q^{15k^2+(6a+1)k}\begin{bmatrix}2n+2a+2\\ 5-5k\end{bmatrix} \times\frac{[10k+2a+2]}{[2n+2a+2]}, \qquad (2)$$

where the symbol $\lfloor x\rfloor$ in the SUM limits is the FLOOR FUNCTION (Paule 1994). The RECIPROCAL of the identity is

$$\sum_{k=0}^{\infty}\frac{q^{k^2+2ak}}{(q;\,q)_{2k+a}} = \prod_{j=0}^{\infty}\frac{1}{(1-q^{2j+1})(1-q^{20j+4a+4})(1-q^{20j-4a+16})} \qquad (3)$$

for $a = 0, 1$ (Paule 1994). For $q = 1$, (1) and (2) become



$$\sum_{-\lfloor a/2\rfloor}^{n}\binom{n+k+a}{n-k} = \sum_{-\lfloor(n+2a+2)/5\rfloor}^{\lfloor n/5\rfloor}\binom{2n+2a+2}{n-5k}\frac{5k+q+1}{n+a+1}. \qquad (4)$$

Andrica's Conjecture

Andrica's conjecture states that, for p_n the nth PRIME NUMBER, the INEQUALITY

$$A_n \equiv \sqrt{p_{n+1}} - \sqrt{p_n} < 1$$

holds, where the discrete function A_n is plotted above. The largest value among the first 1000 PRIMES is for $n = 4$, giving $\sqrt{11} - \sqrt{7} \approx 0.670873$. Since the Andrica function falls asymptotically as n increases so a PRIME GAP of increasing size is needed at large n, it seems likely the CONJECTURE is true. However, it has not yet been proven.

A_n bears a strong resemblance to the PRIME DIFFERENCE FUNCTION, plotted above, the first few values of which are 1, 2, 2, 4, 2, 4, 2, 4, 6, 2, 6, ... (Sloane's A001223).

A generalization of Andrica's conjecture considers the equation

$$p_{n+1}^{x} - p_n^{x} = 1$$

and solves for x. The smallest such x is $x \approx 0.567148$ (Sloane's A038458), known as the SMARANDACHE CONSTANT, which occurs for $p_n = 113$ and $p_{n+1} = 127$ (Perez).

Angle

Given two intersecting LINES or LINE SEGMENTS, the amount of ROTATION about the point of intersection (the VERTEX) required to bring one into correspondence with the other is called the angle θ between them. Angles are usually measured in DEGREES (denoted °), RADIANS (denoted rad, or without a unit), or sometimes GRADIANS (denoted grad).

One full rotation in these three measures corresponds to 360°, 2π rad, or 400 grad. Half a full ROTATION is called a STRAIGHT ANGLE, and a QUARTER of a full rotation is called a RIGHT ANGLE. An angle less than a RIGHT ANGLE is called an ACUTE ANGLE, and an angle greater than a RIGHT ANGLE is called an OBTUSE ANGLE.

The use of DEGREES to measure angles harks back to the Babylonians, whose SEXAGESIMAL number system was based on the number 60. 360° likely arises from the Babylonian year, which was composed of 360 days (12 months of 30 days each). The DEGREE is further divided into 60 ARC MINUTES, and an ARC MINUTE into 60 ARC SECONDS. A more natural measure of an angle is the RADIAN. It has the property that the ARC LENGTH around a CIRCLE is simply given by the radian angle measure times the CIRCLE RADIUS. The RADIAN is also the most useful angle measure in CALCULUS because the DERIVATIVE of TRIGONOMETRIC functions such as

$$\frac{d}{dx}\sin x = \cos x$$

does not require the insertion of multiplicative constants like $\pi/180$. GRADIANS are sometimes used in surveying (they have the nice property that a RIGHT ANGLE is exactly 100 GRADIANS), but are encountered infrequently, if at all, in mathematics.

The concept of an angle can be generalized from the CIRCLE to the SPHERE. The fraction of a SPHERE subtended by an object is measured in STERADIANS, with the entire SPHERE corresponding to 4π STERADIANS.

A ruled SEMICIRCLE used for measuring and drawing angles is called a PROTRACTOR. A COMPASS can also be used to draw circular ARCS of some angular extent.

Angle Bisector

The (interior) bisector of an ANGLE is the LINE or LINE

SEGMENT which cuts it into two equal ANGLES on the same "side" as the ANGLE.

The length of the bisector of ANGLE A_1 in the above TRIANGLE $\Delta A_1A_2A_3$ is given by

$$t_1^2 = a_2a_3\left[1 - \frac{a_1^2}{(a_2+a_3)^2}\right],$$

where $t_i \equiv \overline{A_iT_i}$ and $a_i \equiv \overline{A_jA_k}$. The angle bisectors meet at the INCENTER I, which has TRILINEAR COORDINATES 1:1:1.

Angle Bisector Theorem

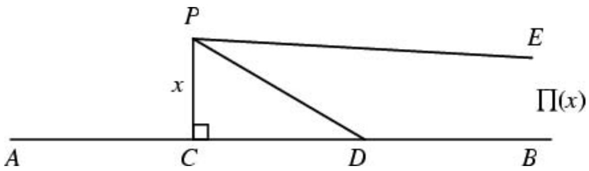
The ANGLE BISECTOR of an ANGLE in a TRIANGLE divides the opposite side in the same RATIO as the sides adjacent to the ANGLE.

Angle Bracket

The combination of a BRA and KET (bra + ket = bracket) which represents the INNER PRODUCT of two functions or vectors,

$$\langle f|g\rangle = \int f(x)g(x)\,dx$$

$$\langle \mathbf{v}|\mathbf{w}\rangle = \mathbf{v}\cdot\mathbf{w}.$$



By itself, the BRA is a COVARIANT 1-VECTOR, and the KET is a CONTRAVARIANT ONE-FORM. These terms are commonly used in quantum mechanics.

Angle of Parallelism

Given a point P and a LINE AB, draw the PERPENDICULAR through P and call it PC. Let PD be any other line from P which meets CB in D. In a HYPERBOLIC GEOMETRY, as D moves off to infinity along CB, then the line PD approaches the limiting line PE, which is said to be parallel to CB at P. The angle $\angle CPE$ which PE makes with PC is then called the angle of parallelism for perpendicular distance x, and is given by

$$\prod(x) = 2\tan^{-1}(e^{-x}).$$

This is known as LOBACHEVSKY'S FORMULA.

TRISECTION

Angle-Preserving Transformation

CONFORMAL MAPPING

Angular Acceleration

The angular acceleration $\boldsymbol{\alpha}$ is defined as the time DERIVATIVE of the ANGULAR VELOCITY $\boldsymbol{\omega}$,

$$\boldsymbol{\alpha} \equiv \frac{d\omega}{dt} = \frac{d^2\theta}{dt^2}\hat{\mathbf{z}} = \frac{\mathbf{a}}{r}.$$

See also ACCELERATION, ANGULAR DISTANCE, ANGULAR VELOCITY

Angular Defect

The DIFFERENCE between the SUM of face ANGLES A_i at a VERTEX of a POLYHEDRON and 2π,

$$\delta = 2\pi - \sum_i A_i.$$

See also DESCARTES TOTAL ANGULAR DEFECT, JUMP ANGLE, SPHERICAL DEFECT

Angular Distance

The angular distance traveled around a CIRCLE is the number of RADIANS the path subtends,

$$\theta \equiv \frac{\ell}{2\pi r} 2\pi = \frac{\ell}{r}.$$

See also ANGULAR ACCELERATION, ANGULAR VELOCITY

Angular Velocity

The angular velocity ω is the time DERIVATIVE of the ANGULAR DISTANCE θ with direction $\hat{z}$ PERPENDICULAR to the plane of angular motion,

$$\omega \equiv \frac{d\theta}{dt}\hat{\mathbf{z}} = \frac{\mathbf{v}}{r}.$$

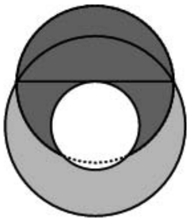
Annealing

SIMULATED ANNEALING

Annihilator

The term annihilator is used in several different ways in various aspects of mathematics. It is most commonly used to mean the SET of all functions satisfying a given set of conditions which is zero on every member of a given SET.



Annuity

PRESENT VALUE

Annulus

The region in common to two concentric CIRCLES of RADII a and b. The AREA of an annulus is

$$A_{\text{annulus}} = \pi(b^2 - a^2).$$

In the above figure, the area of the circle whose diameter is tangent to the inner circle and has endpoints at the outer circle is equal to the area of the annulus.

Annulus Conjecture

ANNULUS THEOREM

Annulus Theorem

Let K_1^n and K_2^n be disjoint bicollared KNOTS in $\mathbb{R}^{n+1}$ or $\mathbb{S}^{n+1}$ and let U denote the open region between them. Then the closure of U is a closed annulus $\mathbb{S}^n \times [0, 1]$. Except for the case $n = 3$, the theorem was proved by Kirby (1969).

Anomalous Cancellation

The simplification of a FRACTION a/b which gives a correct answer by "canceling" DIGITS of a and b. There are only four such cases for NUMERATOR and DENOMINATORS of two DIGITS in base 10: $64/16 =$

$4/1 = 4$, $98/49 = 8/4 = 2$, $95/19 = 5/1 = 5$, and $65/26 = 5/2$ (Boas 1979).

The concept of anomalous cancellation can be extended to arbitrary bases. PRIME bases have no solutions, but there is a solution corresponding to each PROPER DIVISOR of a COMPOSITE b. When $b-1$ is PRIME, this type of solution is the only one. For base 4, for example, the only solution is $32_4/13_4 = 2_4$. Boas gives a table of solutions for $b \leq 39$. The number of solutions is EVEN unless b is an EVEN SQUARE.

b	N	b	N
4	1	26	4
6	2	27	6
8	2	28	10
9	2	30	6
10	4	32	4
12	4	34	6
14	2	35	6
15	6	36	21
16	7	38	2
18	4	39	6
20	4		
21	10		
22	6		
24	6

Anomalous Number

BENFORD'S LAW

Anonymous

A term in SOCIAL CHOICE THEORY meaning invariance of a result under permutation of voters.

See also DUAL VOTING, MONOTONIC VOTING

Anosov Automorphism

A HYPERBOLIC linear map $\mathbb{R}^n \to \mathbb{R}^n$ with INTEGER entries in the transformation MATRIX and DETERMINANT ± 1 is an ANOSOV DIFFEOMORPHISM of the n-TORUS, called an Anosov automorphism (or HYPERBOLIC AUTOMORPHISM). Here, the term automorphism is used in the GROUP THEORY sense.

Anosov Diffeomorphism

An Anosov diffeomorphism is a C^1 DIFFEOMORPHISM ϕ such that the MANIFOLD M is HYPERBOLIC with respect to ϕ. Very few classes of Anosov diffeomorphisms are known. The best known is ARNOLD'S CAT MAP.

A HYPERBOLIC linear map $\mathbb{R}^n \to \mathbb{R}^n$ with INTEGER entries in the transformation MATRIX and DETERMINANT ± 1 is an Anosov diffeomorphism of the n-TORUS. Not every MANIFOLD admits an Anosov diffeomorphism. Anosov diffeomorphisms are EXPANSIVE, and there are no Anosov diffeomorphisms on the CIRCLE.

It is conjectured that if $\phi: M \to M$ is an Anosov diffeomorphism on a COMPACT RIEMANNIAN MANIFOLD and the NONWANDERING SET $\Omega(\phi)$ of ϕ is M, then ϕ is TOPOLOGICALLY CONJUGATE to a FINITE-TO-ONE FACTOR of an ANOSOV AUTOMORPHISM of a NILMANIFOLD. It has been proved that any Anosov diffeomorphism on the n-TORUS is TOPOLOGICALLY CONJUGATE to an ANOSOV AUTOMORPHISM, and also that Anosov diffeomorphisms are C^1 STRUCTURALLY STABLE.

Anosov Flow

A FLOW defined analogously to the ANOSOV DIFFEOMORPHISM, except that instead of splitting the TANGENT BUNDLE into two invariant sub-BUNDLES, they are split into three (one exponentially contracting, one expanding, and one which is 1-dimensional and tangential to the flow direction).

See also DYNAMICAL SYSTEM

Anosov Map

An important example of a ANOSOV DIFFEOMORPHISM.

$$\begin{bmatrix} x_{n+1} \\ y_{n+1} \end{bmatrix} = \begin{bmatrix} 2 & 1 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} x_n \\ y_n \end{bmatrix},$$

where x_{n+1}, y_{n+1} are computed mod 1.

See also ARNOLD'S CAT MAP

ANOVA

"Analysis of Variance." A STATISTICAL TEST for heterogeneity of MEANS by analysis of group VARIANCES. To apply the test, assume random sampling of a variate y with equal VARIANCES, independent errors, and a NORMAL DISTRIBUTION. Let n be the number of REPLICATES (sets of identical observations) within each of K FACTOR LEVELS (treatment groups), and y_{ij} be the jth observation within FACTOR LEVEL i. Also assume that the ANOVA is "balanced" by restricting n to be the same for each FACTOR LEVEL.

Now define the sum of square terms

$$\mathrm{SST} \equiv \sum_{i=1}^{k} \sum_{j=1}^{n} (y_{ij} - \bar{\bar{y}})^2 \quad (1)$$

$$= \sum_{i=1}^{k} \sum_{j=1}^{n} y_{ij}^2 - \frac{\left(\sum_{i=1}^{k} \sum_{j=1}^{n} y_{ij}\right)^2}{Kn} \quad (2)$$

$$\mathrm{SSA} \equiv \frac{1}{n} \sum_{i=1}^{k} \left(\sum_{j=1}^{n} y_{ij}\right)^2 - \frac{1}{Kn} \left(\sum_{i=1}^{k} \sum_{j=1}^{n} y_{ij}\right)^2 \quad (3)$$

$$\mathrm{SSE} \equiv \sum_{i=1}^{k} \sum_{j=1}^{n} (y_{ij} - \bar{y}_i)^2 \quad (4)$$

$$= \mathrm{SST} - \mathrm{SSA}, \quad (5)$$

which are the total, treatment, and error sums of squares. Here, $\bar{y}_i$ is the mean of observations within FACTOR LEVEL i, and $\bar{\bar{y}}$ is the "group" mean (i.e., mean of means). Compute the entries in the following table, obtaining the P-VALUE corresponding to the calculated F-RATIO of the mean squared values

$$F = \frac{\mathrm{MSA}}{\mathrm{MSE}}. \quad (6)$$

Category	SS	°Freedom	Mean Squared	F-RATIO
Treatment	SSA	$K-1$	$\mathrm{MSA} \equiv \frac{\mathrm{SSA}}{K-1}$	$\frac{\mathrm{MSA}}{\mathrm{MSE}}$
Error	SSE	$K(n-1)$	$\mathrm{MSE} \equiv \frac{\mathrm{SSE}}{K(n-1)}$	
Total	SST	$Kn-1$	$\mathrm{MST} \equiv \frac{\mathrm{SST}}{Kn-1}$	

If the P-VALUE is small, reject the NULL HYPOTHESIS that all MEANS are the same for the different groups.

Anticevian Triangle

Given a center $\alpha : \beta : \gamma$, the anticevian triangle is defined as the TRIANGLE with VERTICES $-\alpha : \beta : \gamma$, $\alpha : -\beta : \gamma$, and $\alpha : \beta : -\gamma$. If $A'B'C'$ is the CEVIAN TRIANGLE of X and $A''B''C''$ is an anticevian triangle, then X and A'' are HARMONIC CONJUGATE POINTS with respect to A and A'.

See also CEVIAN TRIANGLE

References

Kimberling, C. "Central Points and Central Lines in the Plane of a Triangle." *Math. Mag.* **67**, 163–87, 1994.

Antichain

Let P be a finite PARTIALLY ORDERED SET. An antichain in P is a set of pairwise incomparable elements (e.g., a family of SUBSETS such that, for any two of them, neither is a SUBSET of the other). Antichains are also called Sperner systems in older literature (Comtet 1974).

The following table gives the antichains on n-set $\{1, 2, \ldots, n\}$ for small n.

n	antichains
1	$\emptyset, \{(1)\}$
2	$\emptyset$, $\{\{1\}\}$, $\{\{2\}\}$, $\{\{1\}, \{2\}\}$, $\{\{1, 2\}\}$
3	$\emptyset$, $\{\{1\}\}$, $\{\{2\}\}$, $\{\{3\}\}$, $\{\{1, 2\}\}$,
	$\{\{1, 3\}\}$, $\{\{2, 3\}\}$, $\{\{1\}, \{2\}\}$, $\{\{1\}, \{3\}\}$,
	$\{\{2\}, \{3\}\}$, $\{\{1, 2, 3\}\}$, $\{\{1\}, \{2, 3\}\}$, $\{\{1, 2\}, \{2, 3\}\}$,
	$\{\{1, 2\}, \{1, 3\}\}$, $\{\{1, 2\}, \{3\}\}$, $\{\{2\}, \{1, 3\}\}$, $\{\{2, 3\}, \{1,3\}\}$,
	$\{\{1\}, \{2\}, \{3\}\}$, $\{\{1, 2\}, \{2, 3\}, \{1, 3\}\}$

The number of antichains on the n-set $\{1, 2, \ldots, n\}$ for $n = 1, 2, \ldots$, are 1, 2, 5, 19, 167, ... (Sloane's A014466). If the EMPTY SET is not considered a valid antichain, then these reduce to 0, 1, 4, 18, 166, ... (Sloane's A007153; Comtet 1974, p. 273). The numbers obtained by adding one to Sloane's A014466, 2, 3, 6, 20, 168, 7581, 7828354, ... (Sloane's A000372), are also frequently encountered (Speciner 1972).

The number of antichains on the n-set are equal to the number of monotonic increasing Boolean functions of n variables, and also the number of free distributive lattices with n generators (Comtet 1974, p. 273). Determining these numbers is known as DEDEKIND'S PROBLEM, and the numbers in each of these sequences are sometimes called Dedekind numbers (Sloane).

The WIDTH of P is the maximum CARDINALITY of an ANTICHAIN in P. For a PARTIAL ORDER, the size of the longest ANTICHAIN is called the WIDTH $w(P)$. Sperner (1928) proved that the maximum width of an antichain containing n elements is

$$w_{\max(n)} = \binom{n}{\lfloor n/2 \rfloor},$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT and $\lfloor n \rfloor$ is the FLOOR FUNCTION.

Anticlastic

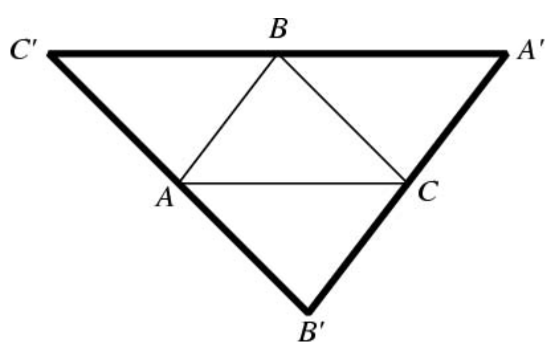
When the GAUSSIAN CURVATURE K is everywhere NEGATIVE, a SURFACE is called anticlastic and is saddle-shaped. A SURFACE on which K is everywhere POSITIVE is called SYNCLASTIC. A point at which the GAUSSIAN CURVATURE is NEGATIVE is called a HYPERBOLIC POINT.

See also ELLIPTIC POINT, GAUSSIAN QUADRATURE, HYPERBOLIC POINT, PARABOLIC POINT, PLANAR POINT, SYNCLASTIC

Anticommutative

An OPERATOR $*$ for which $a * b = -b * a$ is said to be anticommutative.

See also COMMUTATIVE



Anticommutator

For OPERATORS $\tilde{A}$ and $\tilde{B}$, the anticommutator is defined by

$$\{\tilde{A}, \tilde{B}\} \equiv \tilde{A}\tilde{B} + \tilde{B}\tilde{A}.$$

See also COMMUTATOR, JORDAN ALGEBRA, JORDAN PRODUCT

Anticomplementary Triangle

A TRIANGLE $\Delta A'B'C'$ which has a given TRIANGLE ΔABC as its MEDIAL TRIANGLE. The TRILINEAR COORDINATES of the anticomplementary triangle are

$$A' = -a^{-1} : b^{-1} : c^{-1}$$

$$B' = a^{-1} : -b^{-1} : c^{-1}$$

$$C' = a^{-1} : b^{-1} : -c^{-1}.$$

Antigonal Points

Given $\angle AXB + \angle AYB = \pi$ RADIANS in the above figure, then X and Y are said to be antigonal points with respect to A and B.

Antihomography

A CIRCLE-preserving TRANSFORMATION composed of an ODD number of INVERSIONS.

See also HOMOGRAPHY

Antihomologous Points

Two points which are COLLINEAR with respect to a SIMILITUDE CENTER but are not HOMOLOGOUS POINTS. Four interesting theorems from Johnson (1929) follow.

1. Two pairs of antihomologous points form inversely similar triangles with the HOMOTHETIC CENTER.
2. The PRODUCT of distances from a HOMOTHETIC CENTER to two antihomologous points is a constant.
3. Any two pairs of points which are antihomologous with respect to a SIMILITUDE CENTER lie on a CIRCLE.
4. The tangents to two CIRCLES at antihomologous points make equal ANGLES with the LINE through the points.

Antilaplacian

The antilaplacian of u with respect to x is a function whose LAPLACIAN with respect to x equals u. The antilaplacian is never unique.

See also LAPLACIAN

Antilinear

An antilinear OPERATOR $\tilde{A}$ satisfies the following two properties:

$$\tilde{A}[f_1(x)+f_2(x)]=\tilde{A}f_1(x)+\tilde{A}f_2(x)$$

$$\tilde{A}cf(x)=\tilde{c}\tilde{A}f(x),$$

where $\tilde{c}$ is the COMPLEX CONJUGATE of c.

Antimagic Square

An antimagic square is an $n \times n$ ARRAY of integers from 1 to n^2 such that each row, column, and main diagonal produces a different sum such that these sums form a SEQUENCE of consecutive integers. It is therefore a special case of a HETEROSQUARE. Antimagic squares of orders 4– are illustrated above (Madachy 1979). For the 4×4 square, the sums are 30, 31, 32, ..., 39; for the 5×5 square they are 59, 60, 61, ..., 70; and so on.

Let an antimagic square of order n have entries 0, 1, ..., n^2-2, n^2-1, and let

$$M(n)\equiv\tfrac{1}{2}n(n^2+1)$$

be the magic constant. Then if and antimagic square of order n exists, it is either positive with sums $[M(n)-n,\ M(n)+n+1]$, or negative with sums $[M(n)-n-1,\ M(n)+n]$ (Madachy 1979).

Antimagic squares of orders one, two, and three are impossible. In the case of the 3×3 square, there is no known method of proof of this fact except by case analysis or enumeration by computer. There are 18 families of antimagic squares of order four. The total

number of antimagic squares of orders 1, 2, ... modulo the full group of symmetries (reflection, rotation, complementation, and exchanges) are 0, 0, 0, 299710, ... (Sloane's A050257; Cormie).

Abe (1994) and Madachy (1979) ask for methods of constructing antimagic squares of every order. Recently, J. Cormie and V. Linek have developed general constructions for squares of order n for all $n > 3$, as well as for bordering antimagic squares.

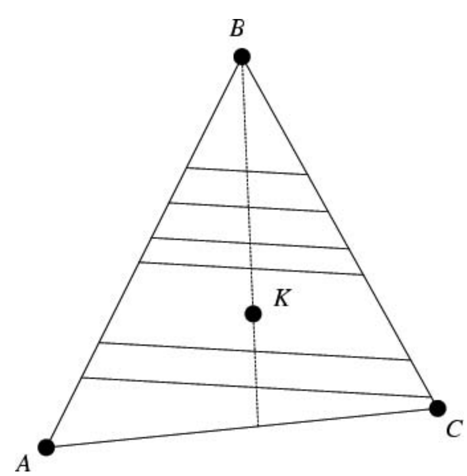
Antimorphic Number

ANTIMORPH

Antinomy

A PARADOX or contradiction.



Antiparallel

Two lines PQ and RS are said to be antiparallel with respect to the sides of an ANGLE A if they make the same angle in the opposite senses with the BISECTOR of that angle. If PQ and RS are antiparallel with respect to PR and QS, then the latter are also antiparallel with respect to the former. Furthermore, if PQ and RS are antiparallel, then the points P, Q, R, and S are CONCYCLIC (Johnson 1929, p. 172; Honsberger 1995, pp. 87–8).

There are a number of fundamental relationships involving a triangle and antiparallel lines (Johnson 1929, pp. 172–73).

1. The line joining the feet to two ALTITUDES of a triangle is antiparallel to the third side.
2. The tangent to a triangle's CIRCUMCIRCLE at a vertex is antiparallel to the opposite side.
3. The radius of the CIRCUMCIRCLE at a vertex is perpendicular to all lines antiparallel to the opposite sides.

In a TRIANGLE ΔABC, a SYMMEDIAN BK bisects all segments antiparallel to a given side AC (Honsberger 1995, p. 88). Furthermore, every antiparallel to BC in ΔABC is PARALLEL to the tangent to the CIRCUMCIRCLE of ΔABC at A (Honsberger 1995, p. 98).

Antipedal Triangle

The antipedal triangle A of a given TRIANGLE T is the TRIANGLE of which T is the PEDAL TRIANGLE. For a TRIANGLE with TRILINEAR COORDINATES $\alpha : \beta : \gamma$ and ANGLES A, B, and C, the antipedal triangle has VERTICES with TRILINEAR COORDINATES

$$-(\beta+\alpha\cos C)(\gamma+\alpha\cos B) : (\gamma+\alpha\cos B)(\alpha+\beta\cos C) :$$
$$(\beta+\alpha\cos C)(\alpha+\gamma\cos B)$$

$$(\gamma+\beta\cos A)(\beta+\alpha\cos C) : -(\gamma+\beta\cos A)(\alpha+\beta\cos C) :$$
$$(\alpha+\beta\cos C)(\beta+\gamma\cos A)$$

$$(\beta+\gamma\cos A)(\gamma+\alpha\cos B) : (\alpha+\gamma\cos B)(\gamma+\beta\cos A) :$$
$$-(\alpha+\gamma\cos B)(\beta+\gamma\cos A) :$$

The ISOGONAL CONJUGATE of the ANTIPEDAL TRIANGLE of a given TRIANGLE is HOMOTHETIC with the original TRIANGLE. Furthermore, the PRODUCT of their AREAS equals the SQUARE of the AREA of the original TRIANGLE (Gallatly 1913).

Tietze, H. *Famous Problems of Mathematics: Solved and Unsolved Mathematics Problems from Antiquity to Modern Times.* New York: Graylock Press, p. 25, 1965.

Antiprism

A SEMIREGULAR POLYHEDRON constructed with 2 n-gons and $2n$ TRIANGLES. The nets are particularly simple, consisting of two n-gons on top and bottom, separated by a ribbon of $2n$ triangles, with the two n-gons being offset by one ribbon segment.

The SAGITTA of a regular n-gon of side length a has length

$$s = \frac{1}{2} a \tan\left(\frac{\pi}{2n}\right) \quad (1)$$

Let d be the length of a lateral edge when the top and bottom bases separated by a distance h, then

$$s^2 + (\tfrac{1}{2}a)^2 + h^2 = d^2, \quad (2)$$

so

$$d = \tfrac{1}{2} \sqrt{4h^2 + a^2 \sec^2\left(\frac{\pi}{2n}\right)}. \quad (3)$$

For an antiprism of side lengths 1, $a = d = 1$, and solving for h gives

$$h = \sqrt{1 - \tfrac{1}{4} \sec^2\left(\frac{\pi}{2n}\right)}. \quad (4)$$

The CIRCUMRADIUS $R_{\rm circ}$ of an antiprism is given by

$$R_{\rm circ} = \sqrt{\left(\tfrac{1}{2} h\right)^2 + R^2} = \tfrac{1}{4} \sqrt{4 \csc^2\left(\frac{\pi}{2n}\right)}, \quad (5)$$

where

$$R = \tfrac{1}{2} \csc\left(\frac{\pi}{n}\right) \quad (6)$$

is the CIRCUMRADIUS of one of the bases.

The TETRAHEDRON can be considered a degenerate 2-antiprism and the 3-antiprism of height $\sqrt{6}a/3$ (for side length a) is simply the OCTAHEDRON. The first few heights h_n producing unit antiprisms for $a = 1$ are

$$h_3 = \tfrac{1}{2} \sqrt{6} \quad (7)$$

$$h_4 = 2^{1/4} \quad (8)$$

$$h_5 = \sqrt{\tfrac{1}{10}(5 + \sqrt{5})} \quad (9)$$

$$h_6 = \sqrt{\sqrt{3} - 1} \quad (10)$$

$$h_8 = \sqrt{\sqrt{5 + \tfrac{7}{2}\sqrt{2}} - 1 - \sqrt{2}}. \quad (11)$$

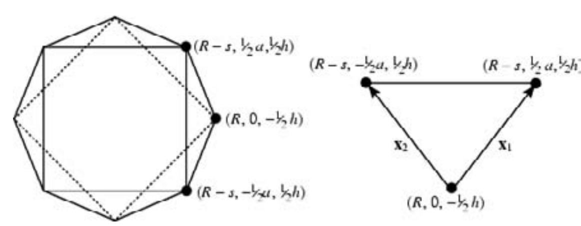
The DUALS are the TRAPEZOHEDRA. The SURFACE AREA of a n-gonal antiprism is

$$\begin{aligned} S &= 2A_{n-\text{gon}} + 2nA_\Delta \\ &= 2\left[\tfrac{1}{4} na^2 \cot\left(\frac{\pi}{n}\right)\right] + 2n\left(\tfrac{1}{2} a\right)\sqrt{s^2 + h^2} \\ &= \tfrac{1}{2} na \left[a \cot\left(\frac{\pi}{n}\right) + 2\sqrt{h^2 + \tfrac{1}{4} a^2 \tan^2\left(\frac{\pi}{2n}\right)}\right]. \end{aligned} \quad (12)$$

If $h = a$, this simplifies to

$$S = \tfrac{1}{2} na^2 \left[\cot\left(\frac{\pi}{n}\right) + \sqrt{3}\right]. \quad (13)$$

The first few are



$$S_3 = 2\sqrt{3} \quad (14)$$

$$S_4 = 2(1 + \sqrt{3}) \quad (15)$$

$$S_5 = \tfrac{1}{2}\left(5\sqrt{3} + \sqrt{25 + 10\sqrt{5}}\right) \quad (16)$$

$$S_6 = 6\sqrt{3} \quad (17)$$

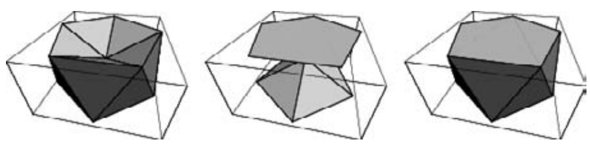
$$S_8 = 4(1 + \sqrt{2} + \sqrt{3}). \quad (18)$$

To find the volume, label vertices as in the above figure. Then the vectors $\mathbf{v}_1$ and $\mathbf{v}_2$ are given by

$$\mathbf{v}_1 = (-s,\ \tfrac{1}{2} a,\ h) \quad (19)$$

$$\mathbf{v}_2 = (-s,\ -\tfrac{1}{2} a,\ h), \quad (20)$$

so the normal to one of the lateral facial planes is



$$\mathbf{n} = \mathbf{v}_1 \times \mathbf{v}_2 = (ah,\ 0,\ as), \quad (21)$$

and the unit normal is

$$\begin{aligned} \hat{\mathbf{n}} &= \frac{\mathbf{v}_1 \times \mathbf{v}_2}{|\mathbf{v}_1 \times \mathbf{v}_2|} \\ &= \left(\frac{ah}{\sqrt{a^2(h^2 + s^2)}},\ 0,\ \frac{as}{\sqrt{a^2(h^2 + s^2)}}\right). \end{aligned} \quad (22)$$

The height of a pyramid with apex at the center and having the triangle determined by $\mathbf{x}_1$ and $\mathbf{x}_2$ as the base is then given by the projection of a vector from the origin to a point on the plane onto the normal,

$$\begin{aligned} h_{\rm pyr} &= \hat{u} \cdot (R-s,\ -\tfrac{1}{2}a,\ \tfrac{1}{2}h) = \hat{u} \cdot (R-s,\ -\tfrac{1}{2}a,\ \tfrac{1}{2}h) \\ &= \hat{u} \cdot (R,\ 0,\ \tfrac{1}{2}h) \qquad (23) \\ &= \frac{a^2 h \cot\left(\frac{\pi}{2n}\right)}{4\sqrt{a^2\left[h^2+\frac{1}{4}a^2\tan^2\left(\frac{\pi}{2n}\right)\right]}}. \qquad (24) \end{aligned}$$

The total volume of the $2n$ pyramids having the lateral faces as bases is therefore

$$\begin{aligned} V_{\rm pyr} &= (2n)\left[\tfrac{1}{3}h_{\rm pyr}(\tfrac{1}{2}a\ \sqrt{s^2+h^2})\right] \\ &= \tfrac{1}{12}a^2 h \cot\left(\frac{\pi}{2n}\right) \qquad (25) \end{aligned}$$

Plugging in h and setting $a=1$ gives

$$V_{\rm pyr} = \tfrac{1}{12}n\cot\left(\frac{\pi}{2n}\right)\sqrt{1-\tfrac{1}{4}\sec^2\left(\frac{\pi}{2n}\right)}. \qquad (26)$$

The two pyramids having the upper and lower surfaces as bases contribute a volume

$$\begin{aligned} V_{\rm hase} &= 2\left(\tfrac{1}{2}\right)\left(\tfrac{1}{2}h\right)\left[\tfrac{1}{4}na^2\cot\left(\frac{\pi}{n}\right)\right] \\ &= \tfrac{1}{12}na^2\, h\cot\left(\frac{\pi}{n}\right). \qquad (27) \end{aligned}$$

Combining the two, setting $a=1$, and plugging in the height h to get unit lateral edges gives the total volume as the somewhat complicated expression

$$V = \tfrac{1}{12}n\left[\cot\left(\frac{\pi}{2n}\right)+\cot\left(\frac{\pi}{n}\right)\right]\sqrt{1-\tfrac{1}{4}\sec^2\left(\frac{\pi}{2n}\right)}. \qquad (28)$$

The volumes of the first few unit antiprisms are therefore given by

$$V_3 = \tfrac{1}{3}\sqrt{2} \qquad (29)$$

$$V_4 = \tfrac{1}{3}\sqrt{4+3\sqrt{2}} \qquad (30)$$

$$V_5 = \tfrac{1}{6}(5+2\sqrt{5}) \qquad (31)$$

$$v_6 = \sqrt{2\left(1+\sqrt{3}\right)} \qquad (32)$$

KOCH ANTISNOWFLAKE

Antisphere

PSEUDOSPHERE

Antisquare Number

A number OF THE FORM $p^a \cdot A$ is said to be an antisquare if it fails to be a SQUARE NUMBER for the two reasons that a is ODD and A is a nonsquare modulo p.

See also SQUARE NUMBER, SQUAREFREE, SQUAREFUL

Antisymmetric

A quantity which changes SIGN when indices are reversed. For example, $A_{ij} \equiv a_i - a_j$ is antisymmetric since $A_{ij} = -A_{ji}$.

See also ANTISYMMETRIC MATRIX, ANTISYMMETRIC TENSOR, SYMMETRIC

Antisymmetric Matrix

An antisymmetric matrix is a MATRIX which satisfies the identity

$$\mathsf{A} = -\mathsf{A}^{\rm T} \qquad (1)$$

where $\mathsf{A}^{\rm T}$ is the matrix TRANSPOSE. A matrix m may

be tested to see if it is antisymmetric using the *Mathematica* function

```
AntisymmetricQ[m_List?MatrixQ] := (m === -
Transpose[m])
```

In component notation, this becomes

$$a_{ij} = -a_{ji}. \tag{2}$$

Letting $k = i = j$, the requirement becomes

$$a_{kk} = -a_{kk}, \tag{3}$$

so an antisymmetric matrix must have zeros on its diagonal. The general 3×3 antisymmetric matrix is OF THE FORM

$$\begin{bmatrix} 0 & a_{12} & a_{13} \\ -a_{12} & 0 & a_{23} \\ -a_{13} & -a_{23} & 0 \end{bmatrix}. \tag{4}$$

Applying A^{-1} to both sides of the antisymmetry condition gives

$$-\mathsf{A}^{-1}\mathsf{A}^{\mathrm{T}} = 1. \tag{5}$$

Any SQUARE MATRIX can be expressed as the sum of symmetric and antisymmetric parts. Write

$$\mathsf{A} = \tfrac{1}{2}(\mathsf{A} + \mathsf{A}^{\mathrm{T}}) + \tfrac{1}{2}(\mathsf{A} - \mathsf{A}^{\mathrm{T}}). \tag{6}$$

But

$$\mathsf{A} = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix} \tag{7}$$

$$\mathsf{A}^{\mathrm{T}} = \begin{bmatrix} a_{11} & a_{21} & \cdots & a_{n1} \\ a_{12} & a_{22} & \cdots & a_{n2} \\ \vdots & \vdots & \ddots & \vdots \\ a_{1n} & a_{2n} & \cdots & a_{nn} \end{bmatrix}, \tag{8}$$

so

$$\mathsf{A} + \mathsf{A}^{\mathrm{T}} = \begin{bmatrix} 2a_{11} & a_{12} + a_{21} & \cdots & a_{1n} + a_{n1} \\ a_{12} + a_{21} & 2a_{22} & \cdots & a_{2n} + a_{n2} \\ \vdots & \vdots & \ddots & \vdots \\ a_{1n} + a_{n1} & a_{2n} + a_{n2} & \cdots & 2a_{nn} \end{bmatrix}, \tag{9}$$

which is symmetric, and

$$\mathsf{A} - \mathsf{A}^{\mathrm{T}} = \begin{bmatrix} 0 & a_{12} - a_{21} & \cdots & a_{1n} - a_{n1} \\ -(a_{12} - a_{21}) & 0 & \cdots & a_{2n} - a_{n2} \\ \vdots & \vdots & \ddots & \vdots \\ -(a_{1n} - a_{n1}) & -(a_{2n} - a_{n2}) & \cdots & 0 \end{bmatrix}, \tag{10}$$

which is antisymmetric.

See also SKEW SYMMETRIC MATRIX, SYMMETRIC MATRIX

Antisymmetric Relation

A RELATION R on a SET S is antisymmetric provided that distinct elements are never both related to one another. In other words xRy and yRx together imply that $x = y$.

Antisymmetric Tensor

An antisymmetric (also called alternating) tensor is a TENSOR which changes sign when two indices are switched. For example, a tensor $A^{x_1, \cdots, x_n}$ such that

$$A^{x_1, \cdots, x_i, \cdots, x_j, \cdots, x_n} = -A^{x_1, \cdots, x_j, \cdots, x_i, \cdots, x_n} \tag{1}$$

is antisymmetric.

The simplest nontrivial antisymmetric tensor is therefore an antisymmetric rank-2 tensor, which satisfies

$$A^{mn} = -A^{nm}. \tag{2}$$

Furthermore, any rank-2 TENSOR can be written as a sum of SYMMETRIC and antisymmetric parts as

$$A^{mn} = \tfrac{1}{2}(A^{mn} + A^{nm}) + \tfrac{1}{2}(A^{mn} - A^{nm}). \tag{3}$$

The antisymmetric part of a tensor A^{ab} is sometimes denoted using the special notation

$$A^{[ab]} = \tfrac{1}{2}(A^{ab} - A^{ba}). \tag{4}$$

For a general rank-n TENSOR,

$$A^{[a_1 \cdots a_n]} \equiv \frac{1}{n!} \epsilon_{a_1 \cdots a_n} \sum_{\text{permutations}} A^{a_1 \cdots a_n}, \tag{5}$$

where $\epsilon_{a_1 \cdots a_n}$ is the PERMUTATION SYMBOL. Symbols for the symmetric and antisymmetric parts of tensors can be combined, for example

$$T^{(ab)c}_{[d]} = \tfrac{1}{4}(T^{abc}_{de} + T^{bac}_{de} - T^{abc}_{ed} - T^{bac}_{ed}). \tag{6}$$

(Wald 1984, p. 26).

Apéry Number

The numbers defined by

$$A_n = \sum_{k=0}^{n} \binom{n}{k}^2 \binom{n+k}{k}^2 = \sum_{k=0}^{n} \frac{[(n+k!]^2}{(k!)^4[(n-k)!]^2}, \tag{1}$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT. The first few for $n = 0, 1, 2, \ldots$ are 1, 5, 73, 1445, 33001, 819005, ... (Sloane's A005259). They are also given by the RECURRENCE RELATION

$$a_n = \frac{(34n^3 - 51n^2 + 27n - 5)a_{n-1} + (n-1)^3 a_{n-2}}{n^3} \tag{2}$$

(Beukers 1987). There is also an associated set of numbers

$$B_n = \sum_{k=0}^{n} \binom{n}{k}^2 \binom{n+k}{k} \tag{3}$$

(Beukers 1987). The values for $n = 0, 1, \ldots$ are 1, 3, 19, 147, 1251, 11253, 104959, ... (Sloane's A005258).

Both A_n and B_n arose in Apéry's irrationality proof of $\zeta(2)$ and $\zeta(3)$ (van der Poorten 1979, Beukers 1987). They satisfy some surprising congruence properties,

$$A_{mp^r-1} \equiv A_{mp^{r-1}-1} \pmod{p^{3r}} \tag{4}$$

$$B_{mp^r-1} \equiv B_{mp^{r-1}-1} \pmod{p^{3r}} \tag{5}$$

for p a PRIME ≥ 5 and $m,\ r \in \mathbb{N}$ (Beukers 1985, 1987), as well as

$$B_{(p-1)/2} \equiv \begin{cases} 4a^2 - 2p \pmod p & \text{if } p = a^2 + b^2,\ a \text{ odd} \\ 0 \pmod p & \text{if } p \equiv 3 \pmod 4 \end{cases}$$

(Stienstra and Beukers 1985, Beukers 1987). Defining γ_n from the GENERATING FUNCTION

$$\sum_{n=1}^{\infty} \gamma_n q^n = q \prod_{n=1}^{\infty} (1-q^{2n})^4 (1-q^{4n})^4 \quad (6)$$

gives γ_n of 1, -4, -2, 24, -11, -44, ... (Sloane's A030211; Koike 1984) for $n = 1, 3, 5, ...$, and

$$A_{(p-1)/2} \equiv \gamma_p \pmod p \quad (7)$$

for p an ODD PRIME (Beukers 1987). Furthermore, for p an ODD PRIME and $m,\ r \in \mathbb{N}$,

$$A_{(mp^r-1)/2} - \gamma_p A_{(mp^{r-1}-1)/2} + p^3 A_{mp^{r-2}-1)/2} \equiv 0 \pmod{p^r} \quad (8)$$

(Beukers 1987).

The Apéry numbers are given by the diagonal elements $A_n = A_{nn}$ in the identity

$$A_{mn} = \sum_{k=-\infty}^{\infty} \sum_{j=-\infty}^{\infty} \binom{m}{k}^2 \binom{m}{k}^2 \binom{2m+n-j-k}{2m}$$

$$= \sum_{k=-\infty}^{\infty} \binom{m+n-k}{k}^2 \binom{m+n-2k}{m-k}^2$$

$$= \sum_{k=-\infty}^{\infty} \binom{m}{k}\binom{n}{k}\binom{m+k}{k}\binom{n+k}{k} \quad (9)$$

(Koepf 1998, p. 119).

Apéry's Constant

N.B. A detailed online essay by S. Finch was the starting point for this entry. Apéry's constant is defined by

$$\zeta(3) = 1.2020569\ldots, \quad (1)$$

(Sloane's A002117) where $\zeta(z)$ is the RIEMANN ZETA FUNCTION. Apéry (1979) proved that $\zeta(3)$ is IRRATIONAL, although it is not known if it is TRANSCENDENTAL. Sorokin (1994) and Nesterenko (1996) subsequently constructed independent proofs for the irrationality of $\zeta(3)$ (Hata 2000). $\zeta(3)$ arises naturally in a number of physical problems, including in the second- and third-order terms of the electron's gyromagnetic ratio, computed using quantum electrodynamics.

The CONTINUED FRACTION for $\zeta(3)$ is [1, 4, 1, 18, 1, 1, 1, 4, 1, ...] (Sloane's A013631). The positions at which the numbers 1, 2, ... occur in the continued fraction are 1, 12, 25, 2, 64, 27, 17, 140, 10, ... (Sloane's A033165). The incrementally maximal terms are 1, 4, 18, 30, 428, 458, 527, ... (Sloane's A033166), which occur at positions 1, 2, 4, 29, 63, 572, ... (Sloane's A033167).

The following table summarized progress in computing upper bounds on the IRRATIONALITY MEASURE for $\zeta(3)$. Here, the exact values for two of the numerical bounds are given by

$$\mu_1 = 1 + \frac{6 \ln c_0 + d_0}{6 \ln c_0 - d_0} \approx 7.377956 \quad (2)$$

$$\mu_4 = 1 + \frac{4 \ln(\sqrt{2}+1) + 3}{4 \ln(\sqrt{2}+1) - 3} \approx 13.4178202, \quad (3)$$

where

$$c_0 = \tfrac{1}{9}(362 + 133\sqrt{7}) \quad (4)$$

$$d_0 = 26 + \pi\left[\sqrt{3} - \cot(\tfrac{1}{9}\pi) - \cot(\tfrac{2}{9}\pi)\right] \quad (5)$$

(Hata 2000).

index	upper bound	reference
1	7.377956	Hata (2000)
2	8.830284	Hata (1990)
3	12.74359	Dvornicich and Viola (1987)
4	13.41782	Sorokin (1994), Nesterenko (1996), Prévost (1996)

Beukers (1979) reproduced Apéry's rational approximation to $\zeta(3)$ using the triple integral of the form

$$\int_0^1\int_0^1\int_0^1 \frac{L_n(x)L_n(y)}{1-(1-xy)u}\,dx\,dy\,du, \tag{6}$$

where $L_n(x)$ is a LEGENDRE POLYNOMIAL. This integral is closely related to $\zeta(3)$ using the curious identity

$$\int_0^1\int_0^1\int_0^1 \frac{x^r y^s}{1-(1-xy)u}\,dx\,dy\,du$$
$$=\begin{cases} 2\zeta(3)-\sum_{l=1}^{r}\frac{2}{l^3} & \text{for } r=s \\ \sum_{1=\min(r,\,s)+1}^{\max(r,\,s)} \frac{1}{|r-s|l^2} & \text{for } r\neq s \end{cases}$$
$$=\begin{cases} 2\zeta(3)-H_r^{(3)} & \text{for } r=s \\ \frac{\psi_1(1+\min(r,\,s))-\psi_1(1+\max(r,\,s))}{|r-s|} & \text{for } r\neq s, \end{cases}$$

where $H_r^{(n)}$ is a generalized HARMONIC NUMBER and $\psi_k(x)$ is a POLYGAMMA FUNCTION (Hata 2000).

Sums related to $\zeta(3)$ are

$$\zeta(3)=\frac{5}{2}\sum_{n=1}^{\infty}\frac{(-1)^{n-1}}{n^3\binom{2n}{n}}=\frac{5}{2}\sum_{k=1}^{\infty}\frac{(-1)^{k+1}(k!)^2}{(2k)!k^3} \tag{7}$$

(used by Apéry), and

$$\lambda(3)=\sum_{k=0}^{\infty}\frac{1}{(2k+1)^3}=\tfrac{7}{8}\zeta(3) \tag{8}$$

$$\sum_{k=0}^{\infty}\frac{1}{(3k+1)^3}=\frac{2\pi^3}{81\sqrt{3}}+\tfrac{13}{27}\zeta(3) \tag{9}$$

$$\sum_{k=0}^{\infty}\frac{1}{(4k+1)^3}=\frac{\pi^3}{64}+\tfrac{7}{16}\zeta(3) \tag{10}$$

$$\sum_{k=0}^{\infty}\frac{1}{(6k+1)^3}=\frac{\pi^3}{36\sqrt{3}}+\frac{91}{216}\zeta(3), \tag{11}$$

where $\lambda(z)$ is the DIRICHLET LAMBDA FUNCTION. The above equations are special cases of a general result due to Ramanujan (Berndt 1985). Apéry's proof relied on showing that the sum

$$a(n)\equiv\sum_{k=0}^{n}\binom{n}{k}^2\binom{n+k}{k}^2, \tag{12}$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT, satisfies the RECURRENCE RELATION

$$(n+1)^3a(n+1)-(34n^3+51n^2+27n+5)a(n)$$
$$+n^3a(n-1)=0 \tag{13}$$

(van der Poorten 1979, Zeilberger 1991). The characteristic polynomial $x^2-34x+1$ has roots $(1+\pm\sqrt{2})^4$, so

$$\lim_{n\to\infty}\frac{a_{n+1}}{a_n}=(1+\sqrt{2})^4 \tag{14}$$

is irrational and a_n cannot satisfy a two-term recurrence (Jin and Dickinson 2000).

Apéry's constant is also given by

$$\zeta(3)=\sum_{n=1}^{\infty}\frac{S_{n,\,2}}{n!n}, \tag{15}$$

where $S_{n,\,m}$ is a STIRLING NUMBER OF THE FIRST KIND. This can be rewritten as

$$\zeta(3)=\frac{1}{2}\sum_{n=1}^{\infty}\frac{1}{n^2}\left(1+\frac{1}{2}+\ldots+\frac{1}{n}\right)=\frac{1}{2}\sum_{n=1}^{\infty}\frac{H_n}{n^2}, \tag{16}$$

where H_n is the nth HARMONIC NUMBER (Castellanos 1988).

INTEGRALS for $\zeta(3)$ include

$$\zeta(3)=\frac{1}{2}\int_0^{\infty}\frac{t^2}{e^t-1}\,dt \tag{17}$$

$$=\frac{8}{7}\left[\tfrac{1}{4}\pi^2\ln 2+2\int_0^{\pi/4}x\ln(\sin x)\,dx\right]. \tag{18}$$

Gosper (1990) gave

$$\zeta(3)=\frac{1}{4}\sum_{k=1}^{\infty}\frac{30k-11}{(2k-1)k^3\binom{2k}{k}^2}. \tag{19}$$

A CONTINUED FRACTION involving Apéry's constant is

$$\frac{6}{\zeta(3)}=5-\frac{1^6}{117-}\,\frac{2^6}{535-}\cdots\frac{n^6}{34n^3+51n^2+27n+5-}\cdots \tag{20}$$

(Apéry 1979, Le Lionnais 1983). Amdeberhan (1996) used WILF-ZEILBERGER PAIRS $(F,\,G)$ with

$$F(n,\,k)=\frac{(-1)^k k!^2(sn-k-1)!}{(sn+k+1)!(k+1)}, \tag{21}$$

$s=1$ to obtain

$$\zeta(3)=\frac{5}{2}\sum_{n=1}^{\infty}(-1)^{n-1}\frac{1}{\binom{2n}{n}n^3}, \tag{22}$$

For $s=2$,

$$\zeta(3)=\frac{1}{4}\sum_{n=1}^{\infty}(-1)^{n-1}\frac{56n^2-32n+5}{(2n-1)^2}\frac{1}{\binom{3n}{n}\binom{2n}{n}n^3} \tag{23}$$

and for $s=3$,

$$\zeta(3)=\sum_{n=0}^{\infty}\frac{(-1)^n}{72\binom{4n}{n}\binom{3n}{n}}$$
$$\times\frac{6120n+5265n^4+13761n^2+13878n^3+1040}{(4n+1)(4n+3)(n+1)(3n+1)^2(3n+2)^2} \tag{24}$$

(Amdeberhan 1996). The corresponding $G(n,\,k)$ for

$s=1$ and 2 are

$$G(n,\ k)=\frac{2(-1)^k k!^2(n-k)!}{(n+k+1)!(n+1)^2} \tag{25}$$

and

$$G(n,\ k)=\frac{(-1)^k k!^2(2n-k)!(3+4n)(4n^2+6n+k+3)}{2(2n+k+2)!(n+1)^2(2n+1)^2}. \tag{26}$$

Gosper (1996) expressed $\zeta(3)$ as the MATRIX PRODUCT

$$\lim_{N\to\infty}\prod_{n=1}^{N} M_n=\begin{bmatrix}0 & \zeta(3)\\ 0 & 1\end{bmatrix}, \tag{27}$$

where

$$M_n\equiv \begin{bmatrix}\frac{(n+1)^4}{4006(n+\frac{5}{4})^2(n+\frac{7}{4})^2} & \frac{24570n^4+64101n^3+62152n^2+26427n+4154}{31104(n+\frac{1}{3})(n+\frac{1}{2})(n+\frac{2}{3})}\\ 0 & 1\end{bmatrix} \tag{28}$$

which gives 12 bits per term. The first few terms are

$$M_1=\begin{bmatrix}\frac{1}{10600} & \frac{2077}{1728}\\ 0 & 1\end{bmatrix} \tag{29}$$

$$M_2=\begin{bmatrix}\frac{1}{9801} & \frac{7501}{4320}\\ 0 & 1\end{bmatrix} \tag{30}$$

$$M_3=\begin{bmatrix}\frac{9}{67600} & \frac{50501}{20160}\\ 0 & 1\end{bmatrix}, \tag{31}$$

which gives

$$\zeta(3)\approx\frac{423203577229}{352066176000}=1.20205690315732\ldots \tag{32}$$

Given three INTEGERS chosen at random, the probability that no common factor will divide them all is

$$[\zeta(3)]^{-1}\approx 1.20206^{-1}\approx 0.831907. \tag{33}$$

B. Haible and T. Papanikolaou computed $\zeta(3)$ to 1,000,000 DIGITS using a WILF-ZEILBERGER PAIR identity with

$$F(n,\ k)=(-1)^k\ \frac{n!^6(2n-k-1)!k!^3}{2(n+k+1)!^2(2n)!^3}, \tag{34}$$

$s=1$, and $t=1$, giving the rapidly converging

$$\zeta(3)=\sum_{n=0}^{\infty}(-1)^n\ \frac{n!^{10}(205n^2+250n+77)}{64(2n+1)!^5} \tag{35}$$

(Amdeberhan and Zeilberger 1997). The record as of Dec. 1998 was 128 million digits, computed by S. Wedeniwski.

Apoapsis

The greatest radial distance of an ELLIPSE as measured from a FOCUS. Taking $v = \pi$ in the equation of an ELLIPSE

$$r = \frac{a(1-e^2)}{1+e\cos v}$$

gives the apoapsis distance

$$r_+ = a(1+e).$$

Apoapsis for an orbit around the Earth is called apogee, and apoapsis for an orbit around the Sun is called aphelion.

See also ECCENTRICITY, ELLIPSE, FOCUS, PERIAPSIS

Apocalypse Number

A number having 666 DIGITS (where 666 is the BEAST NUMBER) is called an apocalypse number. The FIBONACCI NUMBER F_{3184} is an apocalypse number.

See also APOCALYPTIC NUMBER, BEAST NUMBER, LEVIATHAN NUMBER

References

Pickover, C. A. *Keys to Infinity.* New York: Wiley, pp. 97–02, 1995.

Apocalyptic Number

A number OF THE FORM 2^n which contains the digits 666 (the BEAST NUMBER) is called an APOCALYPTIC NUMBER. 2^{157} is an apocalyptic number. The first few such powers are 157, 192, 218, 220, ... (Sloane's A007356).

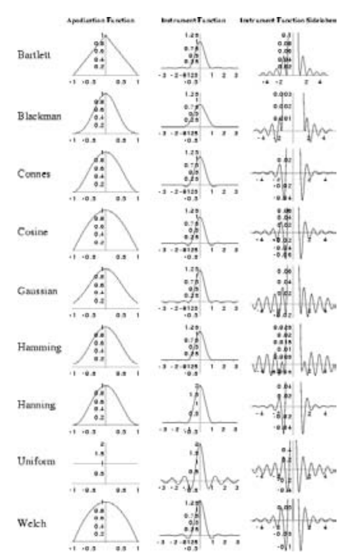
Apodization



The application of an APODIZATION FUNCTION.

Apodization Function

A function (also called a TAPERING FUNCTION) used to bring an interferogram smoothly down to zero at the edges of the sampled region. This suppresses sidelobes which would otherwise be produced, but at the expense of widening the lines and therefore decreasing the resolution.

The following are apodization functions for symmetrical (2-sided) interferograms, together with the INSTRUMENT FUNCTIONS (or APPARATUS FUNCTIONS) they produce and a blowup of the INSTRUMENT FUNCTION sidelobes. The INSTRUMENT FUNCTION $I(k)$ corresponding to a given apodization function $A(x)$ can be computed by taking the finite FOURIER COSINE TRANSFORM,

$$I(k) = \int_{-a}^{a} \cos(2\pi kx)A(x)\,dx. \tag{1}$$

Type	Apodization Function	INSTRUMENT FUNCTION
BARTLETT	$1-\frac{\lvert x\rvert}{\alpha}$	$a\ \mathrm{sinc}^2(\pi ka)$
BLACKMAN	$B_A(x)$	$B_1(k)$
CONNES	$\left(1-\frac{x^2}{a^2}\right)^2$	$8a\sqrt{2\pi}\ \frac{J_{5/2}(2\pi ka)}{(2\pi ka)^{5/2}}$
COSINE	$\cos\left(\frac{\pi x}{2a}\right)$	$\frac{4a\ \cos(2\pi ak)}{\pi(1-16a^2k^2)}$
GAUSSIAN	$e^{-x^2/(2a^2)}$	$2\int_0^\alpha \cos(2\pi kx)e^{-x^2/(2\sigma^2)}\ dx$
HAMMING	$Hm_A(x)$	$Hm_I(k)$
HANNING	$Hn_A(x)$	$Hn_I(k)$
UNIFORM	1	$2a\ \mathrm{sinc}(2\pi ka)$
WELCH	$1-\frac{x^2}{a^2}$	$W_I(k)$

where

$$B_A(x) = 0.42 + 0.5\cos\left(\frac{\pi x}{a}\right) + 0.08\cos\left(\frac{2\pi x}{a}\right) \tag{2}$$

$$B_I(k) = \frac{a(0.84 - 0.36a^2k^2 - 2.17 \times 10^{-19}a^4k^4)\mathrm{sinc}(2\pi ak)}{(1-a^2k^2)(1-4a^2k^3)} \tag{3}$$

$$Hm_A(x) = 0.54 + 0.46\cos\left(\frac{\pi x}{a}\right) \tag{4}$$

$$Hm_I(k) = \frac{a(1.08 - 0.64a^2k^2)\mathrm{sinc}(2\pi ak)}{1-4a^2k^2} \tag{5}$$

$$Hn_A(x) = \cos^2\left(\frac{\pi x}{2a}\right) \tag{6}$$

$$= \frac{1}{2}\left[1+\cos\left(\frac{\pi x}{a}\right)\right] \tag{7}$$

$$Hn_I(k) = \frac{a\ \mathrm{sinc}(2\pi ak)}{1-4a^2k^2} \tag{8}$$

$$= a[\mathrm{sinc}(2\pi ka) + \frac{1}{2}\ \mathrm{sinc}(2\pi ka - \pi) + \frac{1}{2}\ \mathrm{sinc}(2\pi ka \div \pi)] \tag{9}$$

$$W_I(k) = a2\sqrt{2\pi}\ \frac{J_{3/2}(2\pi ka)}{(2\pi ka)^{3/2}} \tag{10}$$

$$= a\ \frac{\sin(2\pi ka) - 2\pi ak\ \cos(2\pi ak)}{2a^3k^3\pi^3}. \tag{11}$$

Type	Instrument Function FWHM	IF Peak	$\frac{\text{Peak}(-)\text{Sidelobe}}{\text{Peak}}$	$\frac{\text{Peak}(+)\text{Sidelobe}}{\text{Peak}}$

Uniform	1.20671	2	–0.217234	0.128375
Welch	1.59044	$\frac{4}{3}$	–0.0861713	0.356044

A general symmetric apodization function $A(x)$ can be written as a FOURIER SERIES

$$A(x) = a_0 + 2\sum_{n=1}^{\infty} a_n\ \cos\left(\frac{n\pi x}{b}\right). \tag{12}$$

where the COEFFICIENTS satisfy

$$a_0 + 2\sum_{n=1}^{\infty} a_n = 1. \tag{13}$$

The corresponding apparatus function is

$$I(t) \equiv \int_{-b}^{b} A(x)e^{-2\pi ikx}\ dx = 2b\{a_0\mathrm{sinc}(2\pi kb) + \sum_{n=1}^{\infty}[\mathrm{sinc}(2\pi kb + n\pi) + \mathrm{sinc}(2\pi kb - n\pi)]\}. \tag{14}$$

To obtain an APODIZATION FUNCTION with zero at $ka = 3/4$, use

$$a_0\ \mathrm{sinc}(\tfrac{3}{2}\ \pi) + a_1[\mathrm{sinc}(\tfrac{5}{2}\ \pi) + \mathrm{sinc}(\tfrac{1}{2}\ \pi) = 0. \tag{15}$$

Plugging in (14),

$$-(1-2a_1)\frac{2}{3\pi} + a_1\left(\frac{2}{5\pi} + \frac{2}{\pi}\right) = -\tfrac{1}{3}(1-2a_1) + a_1(\tfrac{1}{5}+1) = 0 \tag{16}$$

$$a_1(\tfrac{6}{5}+\tfrac{2}{3}) = \tfrac{1}{3} \tag{17}$$

$$a_1 = \frac{\frac{1}{3}}{\frac{6}{5} + \frac{2}{3}} = \frac{5}{6 \cdot 3 + 2 \cdot 5} = \frac{5}{28} \tag{18}$$

$$a_0 = 1 - 2a_1 = \frac{28 - 2 \cdot 5}{28} = \frac{18}{28} = \frac{9}{14}. \tag{19}$$

The HAMMING FUNCTION is close to the requirement that the APPARATUS FUNCTION goes to 0 at $ka = 5/4$, giving

$$a_0 = \frac{25}{46} \approx 0.5435 \tag{20}$$

$$a_1 = \frac{21}{92} \approx 0.2283. \tag{21}$$

The BLACKMAN FUNCTION is chosen so that the APPARATUS FUNCTION goes to 0 at $ka = 5/4$ and $ka = 9/4$, giving

$$a_0 = \frac{3969}{9304} \approx 0.42659 \tag{22}$$

$$a_1 = \frac{1155}{4652} \approx 0.24828 \tag{23}$$

$$a_2 = \frac{715}{18608} \approx 0.38424, \tag{24}$$

Apollonian Gasket

Consider three mutually tangent circles, and draw their inner SODDY CIRCLES. Then draw the inner SODDY CIRCLES of this circle with each pair of the original three, and continue iteratively. The points which are never inside a circle form a set of measure 0 having fractal dimension approximately 1.3058 (Mandelbrot 1983, p. 172).

Apollonius Circles

There are two completely different definitions of the so-called Apollonius circles:

1. The set of all points whose distances from two fixed points are in a constant ratio $1 : \mu$ (Durell 1928, Ogilvy 1990).
2. The eight CIRCLES (two of which are nondegenerate) which solve APOLLONIUS' PROBLEM for three CIRCLES.

Given one side of a TRIANGLE and the ratio of the lengths of the other two sides, the LOCUS of the third VERTEX is the Apollonius circle (of the first type) whose CENTER is on the extension of the given side. For a given TRIANGLE, there are three circles of Apollonius.

Denote the three Apollonius circles (of the first type) of a TRIANGLE by k_1, k_2, and k_3, and their centers L_1, L_2, and L_3. The center L_1 is the intersection of the side A_2A_3 with the tangent to the CIRCUMCIRCLE at A_1. L_1 is also the pole of the SYMMEDIAN POINT K with respect to CIRCUMCIRCLE. The centers L_1, L_2, and L_3 are COLLINEAR on the POLAR of K with regard to its CIRCUMCIRCLE, called the LEMOINE LINE. The circle of Apollonius k_1 is also the locus of a point whose PEDAL TRIANGLE is ISOSCELES such that $\overline{P_1P_2} = \overline{P_1P_3}$.

Let U and V be points on the side line BC of a TRIANGLE ΔABC met by the interior and exterior ANGLE BISECTORS of ANGLES A. The CIRCLE with DIAMETER UV is called the A-Apollonian circle. Similarly, construct the B- and C-Apollonian circles. The Apollonian circles pass through the VERTICES A, B, and C, and through the two ISODYNAMIC POINTS S and S'. The VERTICES of the D-TRIANGLE lie on the respective Apollonius circles.

Apollonius Point

Consider the EXCIRCLES Γ_A, Γ_B, and Γ_C of a TRIANGLE, and the CIRCLE Γ internally TANGENT to all three. Denote the contact point of Γ and Γ_A by A', etc. Then the LINES AA', BB', and CC' CONCUR in this point. It has TRIANGLE CENTER FUNCTION

$$\alpha = \sin^2 A \cos^2[\tfrac{1}{2}(B - C)].$$

Apollonius Pursuit Problem

Given a ship with a known constant direction and speed v, what course should be taken by a chase ship in pursuit (traveling at speed V) in order to intercept the other ship in as short a time as possible? The problem can be solved by finding all points which can be simultaneously reached by both ships, which is an APOLLONIUS CIRCLE with $\mu = v/V$. If the CIRCLE cuts the path of the pursued ship, the intersection is the point towards which the pursuit ship should steer. If the CIRCLE does not cut the path, then it cannot be caught.

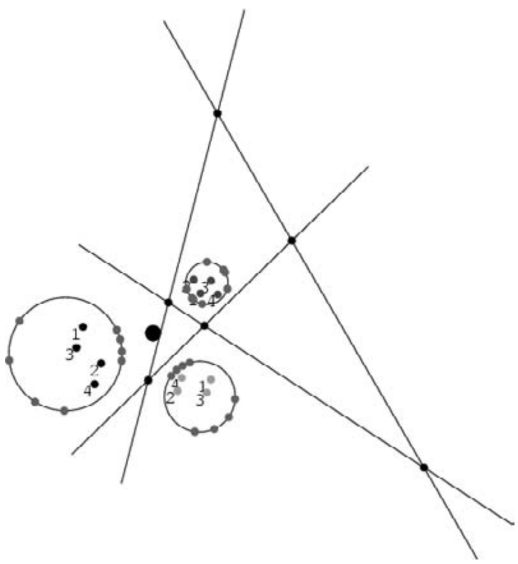
Apollonius Spheres

TANGENT SPHERES



Apollonius' Problem

Given three objects, each of which may be a POINT, LINE, or CIRCLE, draw a CIRCLE that is TANGENT to

each. There are a total of ten cases. The two easiest involve three points or three LINES, and the hardest involves three CIRCLES. Euclid solved the two easiest cases in his *Elements*, and the others (with the exception of the three CIRCLE problem), appeared in the *Tangencies* of Apollonius which was, however, lost. The general problem is, in principle, solvable by STRAIGHTEDGE and COMPASS alone.

The three-CIRCLE problem was solved by Viète (Boyer 1968), and the solutions are called APOLLONIUS CIRCLES. There are eight total solutions. The simplest solution is obtained by solving the three simultaneous quadratic equations

$$(x-x_1)^2+(y-y_1)^2-(r\pm r_1)^2=0 \tag{1}$$

$$(x-x_2)^2+(y-y_2)^2-(r\pm r_2)^2=0 \tag{2}$$

$$(x-x_3)^2+(y-y_3)^2-(r\pm r_3)^2=0 \tag{3}$$

in the three unknowns x, y, r for the eight triplets of signs (Courant and Robbins 1996). Expanding the equations gives

$$(x^2+y^2-r^2)-2xx_i-2yy_i\mp 2rr_i+(x_i^2+y_i^2-r_i^2)=0 \tag{4}$$

for $i=1, 2, 3$. Since the first term is the same for each equation, taking $(2)-(1)$ and $(3)-(1)$ gives

$$ax+by+cr=d \tag{5}$$

$$a'x+b'y+c'r=d', \tag{6}$$

where

$$a=2(x_1-x_2) \tag{7}$$

$$b=2(y_1-y_2) \tag{8}$$

$$c=\pm 2(r_1-r_2) \tag{9}$$

$$d=(x_1^2+y_1^2-r_1^2)-(x_2^2+y_2^2-r_2^2) \tag{10}$$

and similarly for a', b', c' and d' (where the 2 subscripts are replaced by 3s). Solving these two simultaneous linear equations gives

$$x=\frac{b'd-bd'-b'cr+bc'r}{ab'-ba'} \tag{11}$$

$$y=\frac{-a'd+ad'+a'cr-ac'r}{ab'-a'b}, \tag{12}$$

which can then be plugged back into the QUADRATIC EQUATION (1) and solved using the QUADRATIC FORMULA.

Perhaps the most elegant solution is due to Gergonne. It proceeds by locating the six HOMOTHETIC CENTERS (three internal and three external) of the three given CIRCLES. These lie three by three on four lines (illustrated above). Determine the POLES of one of these with respect to each of the three CIRCLES and connect the POLES with the RADICAL CENTER of the CIRCLES. If the connectors meet, then the three pairs of intersections are the points of tangency of two of the eight circles (Petersen 1879, Johnson 1929, Dörrie 1965). To determine *which* two of the eight Apollonius circles are produced by the three pairs, simply take the two which intersect the original three CIRCLES only in a single point of tangency. The procedure, when repeated, gives the other three pairs of CIRCLES.

If the three CIRCLES are mutually tangent, then the eight solutions collapse to two, known as the SODDY CIRCLES.

Larmor (1891) and Lachlan (1893, pp. 244–51) consider the problem of four circles having a common tangent circle.

Apollonius' Theorem

STEWART'S THEOREM

Apothem

Given a CIRCLE, the PERPENDICULAR distance a from the MIDPOINT of a CHORD to the CIRCLE's center is called the apothem. It is also equal to the RADIUS r minus the SAGITTA s,

$$a = r - s.$$

See also CHORD, RADIUS, SAGITTA, SECTOR, SEGMENT

Apparatus Function

INSTRUMENT FUNCTION

Appell Cross Sequence

A sequence

$$s_n^{(\lambda)}(x) = [h(t)]^\lambda s_n(x),$$

where $s_n(x)$ is a SHEFFER SEQUENCE, $h(t)$ is invertible, and λ ranges over the real numbers is called a STEFFENSEN SEQUENCE. If $s_n(x)$ is an associated SHEFFER SEQUENCE, then $s_n^{(\lambda)}$ is called a CROSS SEQUENCE. If $s_n(x) = x^n$, then

$$s_n^\lambda(x) = [h(t)]^\lambda x^n$$

is called an Appell cross sequence.

Examples include the BERNOULLI POLYNOMIAL, EULER POLYNOMIAL, and HERMITE POLYNOMIAL.

See also APPELL SEQUENCE, CROSS SEQUENCE, SHEFFER SEQUENCE, STEFFENSEN SEQUENCE

References

Appell Hypergeometric Function

A formal extension of the HYPERGEOMETRIC FUNCTION to two variables, resulting in four kinds of functions (Appell 1925; Whittaker and Watson 1990, Ex. 22, p. 300),

$$F_1(\alpha;\ \beta,\ \beta';\ \gamma;\ x,\ y) = \sum_{m=0}^\infty \sum_{n=0}^\infty \frac{(\alpha)_{m+n}(\beta)_m(\beta')_n}{m!n!(\gamma)_{m+n}}\ x^m y^n \tag{1}$$

$$F_2(\alpha;\ \beta,\ \beta';\ \gamma,\ \gamma';\ x,\ y) = \sum_{m=0}^\infty \sum_{n=0}^\infty \frac{(\alpha)_{m+n}(\beta)_m(\beta')_n}{m!n!(\gamma)_m(\gamma')_n}\ x^m y^n \tag{2}$$

$$F_3(\alpha,\ \alpha';\ \beta,\ \beta';\ \gamma;\ x,\ y) = \sum_{m=0}^\infty \sum_{n=0}^\infty \frac{(\alpha)_m(\alpha')_n(\beta)_m(\beta')_n}{m!n!(\gamma)_{m+n}}\ x^m y^n \tag{3}$$

$$F_4(\alpha;\ \beta;\ \gamma,\ \gamma';\ x,\ y) = \sum_{m=0}^\infty \sum_{n=0}^\infty \frac{(\alpha)_{m+n}(\beta)_{m+n}}{m!n!(\gamma)_m(\gamma')_n}\ x^m y^n. \tag{4}$$

Appell defined the functions in 1880, and Picard showed in 1881 that they may all be expressed by INTEGRALS OF THE FORM

$$\int_0^1 u^{\alpha}(1-u)^{\beta}(1-xu)^{\gamma}(1-yu)^{\delta}du \quad (5)$$

(Bailey 1934, pp. 76–9). The Appell functions are special cases of the KAMPÉ DE FÉRIET FUNCTION, and are the first four in the set of HORN FUNCTIONS.

In particular, the general integral

$$\int (a+b\sin x+c\cos x)^{\nu}\, dx$$

$$=CF_1\left(n+1;\ \tfrac{1}{2};\ \tfrac{1}{2};\ n+2;\ \frac{a+c\cos x+b\sin x}{a-b\sqrt{1+\frac{c^2}{b^2}}},\right.$$

$$\left.\frac{a+c\cos x+b\sin x}{a+b\sqrt{1+\frac{c^2}{b^2}}}\right), \quad (6)$$

where

$$C=\sec[x+\tan^{-1}(\tfrac{c}{b})](a+c\cos x+b\sin x)^{n+1}$$

$$\times\left[b(n+1)\sqrt{1+\frac{c^2}{b^2}}\right]^{-1}$$

$$\times\sqrt{\frac{b(\sqrt{1+\frac{c^2}{b^2}}-\sin x)-c\cos x}{b\sqrt{1+\frac{c^2}{b^2}}+a}}$$

$$\times\sqrt{\frac{b(\sqrt{1+\frac{c^2}{b^2}}+\sin x)+c\cos x}{b\sqrt{1+\frac{c^2}{b^2}}-a}}, \quad (7)$$

has a closed form in terms of F_1.

$F_1(\alpha;\ \beta,\ \beta';\ \gamma;\ x,\ y)$ reduces to the HYPERGEOMETRIC FUNCTION in the cases

$$F_1(\alpha;\ \beta;\ \beta';\ \gamma;\ 0,\ y)={}_2F_1(\alpha,\ \beta';\ \gamma;\ y) \quad (8)$$

$$F_1(\alpha;\ \beta;\ \beta';\ \gamma;\ x,\ 0)={}_2F_1(\alpha,\ \beta;\ \gamma;\ x) \quad (9)$$

The F_1 function is built into *Mathematica* 4.0 as `AppellF1`[*a*, *b1*, *b2*, *c*, *x*, *y*].

Suetin, P. K. "Classical Appell's Orthogonal Polynomials." Ch. 3 in *Orthogonal Polynomials in Two Variables.* Amsterdam, Netherlands: Gordon and Breach, pp. 63–6, 1999.

Appell Sequence

An Appell sequence is a SHEFFER SEQUENCE for $(g(t),\ t)$. Roman (1984, pp. 86–06) summarizes properties of Appell sequences and gives a number of specific examples.

The sequence $s_n(x)$ is Appell for $g(t)$ IFF

$$\frac{1}{g^{(t)}}e^{y(t)}=\sum_{k=0}^{\infty}\frac{s_k(y)}{k!}\ t^k \quad (1)$$

for all y in the field C of characteristic 0, and IFF

$$s_n(x)=\frac{x^n}{g(t)} \quad (2)$$

(Roman 1984, p. 27). The Appell identity states that the sequence $s_n(x)$ is an Appell sequence IFF

$$s_n(x+y)=\sum_{k=0}^{n}\binom{n}{k}s_k(y)x^{n-k} \quad (3)$$

(Roman 1984, p. 27).

The BERNOULLI POLYNOMIALS, EULER POLYNOMIALS, and HERMITE POLYNOMIALS are Appell sequences (in fact, more specifically, they are APPELL CROSS SEQUENCES).

Approximately Equal

If two quantities A and B are approximately equal, this is written $A \approx B$.

See also DEFINED, EQUAL

Approximately Equal To

APPROXIMATELY EQUAL

Approximation Theory

The mathematical study of how given quantities can be approximated by other (usually simpler) ones under appropriate conditions. Approximation theory also studies the size and properties of the ERROR introduced by approximation. Approximations are often obtained by POWER SERIES expansions in which the higher order terms are dropped.

Arakelov Theory

A formal mathematical theory which introduces "components at infinity" by defining a new type of divisor class group of INTEGERS of a NUMBER FIELD.

The divisor class group is called an "arithmetic surface."

See also ARITHMETIC GEOMETRY

Arbelos

The term "arbelos" means SHOEMAKER'S KNIFE in Greek, and this term is applied to the shaded AREA in the above figure which resembles the blade of a knife used by ancient cobblers (Gardner 1979). Archimedes himself is believed to have been the first mathematician to study the mathematical properties of this figure. The position of the central notch is arbitrary and can be located anywhere along the DIAMETER.

The arbelos satisfies a number of unexpected identities (Gardner 1979, Schoch).

1. Call the diameters of the left and right SEMICIRCLES $r<1$ and $1-r$, respectively, so the diameter of the enclosing SEMICIRCLE is 1. Then the arc length along the bottom of the arbelos is

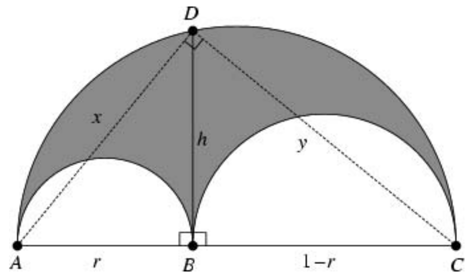
$$L=\pi r+\pi(1-r)=\pi_1$$

so the arc length along the enclosing semicircle is the same as the arc length along the two smaller semicircles.

2. Draw the PERPENDICULAR BD from the tangent of the two SEMICIRCLES to the edge of the large CIRCLE. Then the AREA of the arbelos is the same as the AREA of the CIRCLE with DIAMETER BD. Let $AC=1$ and $r=AB$, then simultaneously solve the equations

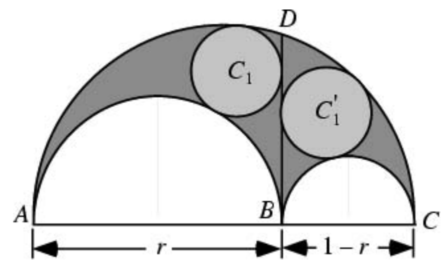
$$r^2+h^2=x^2 \tag{1}$$

$$(1-r)^2+h^2=y^2 \tag{2}$$



$$x^2+y^2=1^2 \tag{3}$$

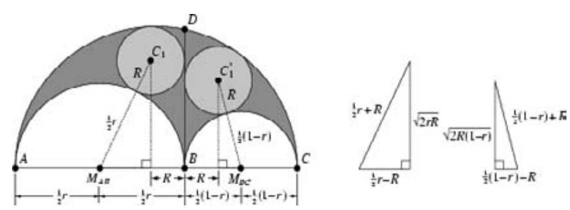
for the sides



$$x=AD=\sqrt{r} \tag{4}$$

$$y=CD=\sqrt{1-r} \tag{5}$$

$$h=BD=\sqrt{r(1-r)}. \tag{6}$$



3. The CIRCLES C_1 and C_1' inscribed on each half of BD on the arbelos (called ARCHIMEDES' CIRCLES) each have DIAMETER $(AB)(BC)/(AC)$.

If $AC=1$ and $AB=r$, then the radius of the Archimedes' circles is

$$R=\tfrac{1}{2}r(1-r). \tag{7}$$

The positions of the circles can be found using the triangles shown above. The lengths of the horizonal legs and hypotenuses are known as indicated, so the vertical legs can be found using the PYTHAGOREAN THEOREM. This then gives the centers of the circles as

$$x_1=r-R=\tfrac{1}{2}r(1+r) \tag{8}$$

$$y_1=\sqrt{2rR}=r\sqrt{1-r} \tag{9}$$

and

$$x_1'=r+R=\tfrac{1}{2}r(3-r) \tag{10}$$

$$y_1'=\sqrt{2R(1-r)}=(1-r)\sqrt{r}. \tag{11}$$

4. Let A' be the point at which the CIRCLE centered at A and of RADIUS $r=AB$ intersects the enclosing SEMICIRCLE, and let C' be the point at which the CIRCLE centered at C of RADIUS $1-r=BC$ intersects the enclosing SEMICIRCLE. Then the smallest CIRCLE C_2 passing through A' and tangent to BD is equal to the smallest CIRCLE C_2' passing through C'

and tangent to BD (Schoch). Moreover, the radii R of these circles are the same as ARCHIMEDES' CIRCLES. Solving

$$(x-\tfrac{1}{2})^2+y^2=(\tfrac{1}{2})^2 \tag{12}$$

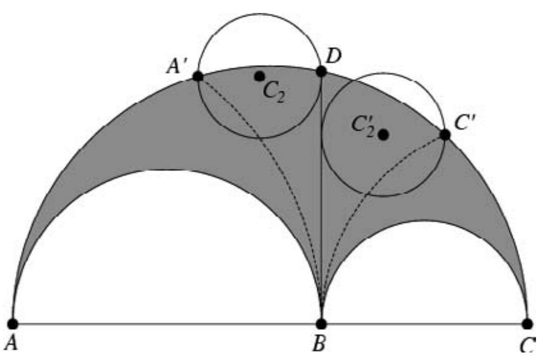
$$x^2+y^2=r^2 \tag{13}$$

gives $(x, y) = (r^2, r\sqrt{1-r^2})$, so the center of C_2 is

$$x_2=r^2+\tfrac{1}{2}r(1-r)=\tfrac{1}{2}r(r+1) \tag{14}$$

$$y_2=r\sqrt{1-r^2}. \tag{15}$$

Similarly, solving



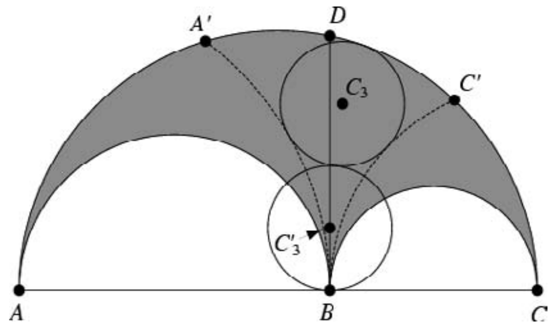
$$(x-\tfrac{1}{2})^2+y^2=(\tfrac{1}{2})^2 \tag{16}$$

$$(x-1)^2+y^2=(1-r)^2 \tag{17}$$

gives $(x, y) = (r(2-r), (1-r)\sqrt{r(2-r)})$, so the center of C_2' is

$$x_2'=r(2-r)-\tfrac{1}{2}r(1-r)=\tfrac{1}{2}r(r-3) \tag{18}$$

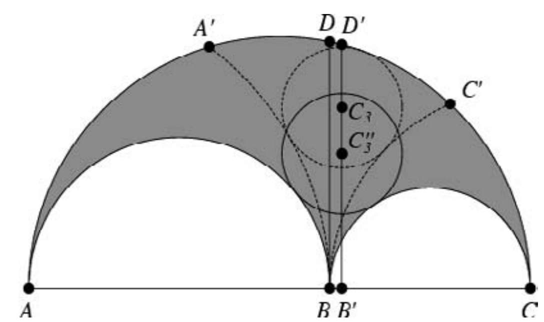
$$y_2'=(1-r)\sqrt{r(2-r)}. \tag{19}$$



5. The APOLLONIUS CIRCLE C_3 of the circles with arcs BA', BC', and $AA'DC'C$ is located at a position

$$x=\tfrac{1}{2}r(1+3r-2r^2) \tag{20}$$

$$y=r(1-r)\sqrt{(2-r)(1+r)} \tag{21}$$



and has radius R equal to that of ARCHIMEDES' CIRCLES (Schoch), as does the smallest circle C_3' passing through B and tangent to C_3.

Furthermore, letting $B'D'$ be the line parallel to BD through the center of CIRCLE C_3, the CIRCLE C_3'' with center on $B'D'$ and tangent to the small semicircles of the arbelos also has radius R (Schoch). The position of the center of C_3'' is given by

$$x_3''=x=\tfrac{1}{2}r(1+3r-2r^2) \tag{22}$$

$$y_3''=\sqrt{(\tfrac{1}{2}r+R)-(x-\tfrac{1}{2}r)^2}$$
$$=r(1-r)\sqrt{1+r-r^2}. \tag{23}$$

The vertical h' position of D' is

$$h'=\sqrt{\tfrac{1}{4}-\tfrac{1}{4}(2r^3-3r^2-r+1)^2}$$
$$=\tfrac{1}{2}\sqrt{r(1-r)(2r^2-3r-1)(2r^2-r-2)}. \tag{24}$$

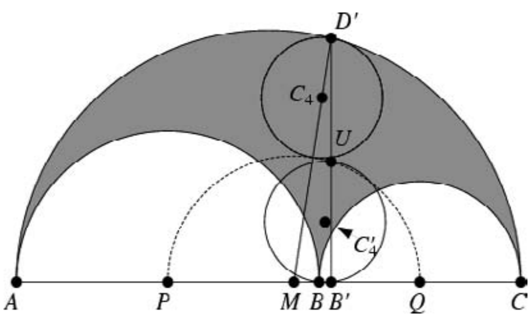
6. Let P be the MIDPOINT of AB, and let Q be the MIDPOINT of BC. Then draw the SEMICIRCLE having PQ as a DIAMETER with center M. This CIRCLE has RADIUS

$$R_{PQ}=\tfrac{1}{2}\{1-\tfrac{1}{2}[r+(1-r)]\}=\tfrac{1}{4}. \tag{25}$$

The smallest circle C_4 through D' touching arc PQ then has radius R (Schoch). Using similar triangles, the center of this circle is at

$$x_4=\frac{r(2r^4-5r^3+3r+1)}{1+4r-4r^2} \tag{26}$$

$$y_4=\frac{2r^2-2r-1}{2(4r^2-4r-1)}$$



$$\times\sqrt{r(1-r)(2r^2-3r-1)(2r^2-r-2)}. \qquad (27)$$

Similarly, let U be the point of intersection of $B'D'$ and the SEMICIRCLE PQ, then the CIRCLE through B, B', and U also has RADIUS R (Schoch). The center of this CIRCLE is at

$$x_4' = \tfrac{1}{4}r(3+3r-2r^2) \qquad (28)$$

$$y_4' = \tfrac{1}{4}r(1-r)$$

$$\times\sqrt{(2r+1)(3-2r)}. \qquad (29)$$

Consider the circle X of RADIUS r_X which is tangent to the two interior semicircles. Its position and radius are obtained by solving the simultaneous equations

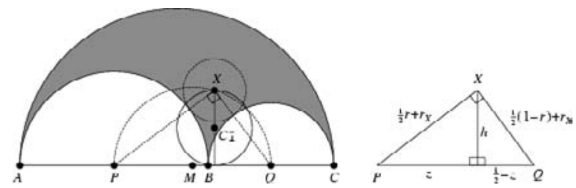
$$h^2+z^2=(\tfrac{1}{2}r+r_X)^2 \qquad (30)$$

$$h^2+(\tfrac{1}{2}-z)^2=[\tfrac{1}{2}(1-r)+r_X]^2 \qquad (31)$$

$$(\tfrac{1}{2}r+r_X)^2+[\tfrac{1}{2}(1-r)+r_X]^2=(\tfrac{1}{4})^2. \qquad (32)$$

giving

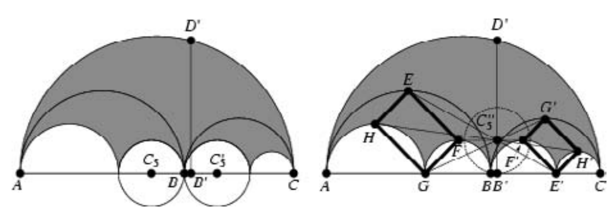
$$z=\tfrac{1}{4}+\tfrac{1}{4}(2r-1)\sqrt{1+4r-4r^2} \qquad (33)$$



$$h=r(1-r) \qquad (34)$$

$$r_X=\tfrac{1}{4}(\sqrt{1+4r-4r^2}-1). \qquad (35)$$

Letting C_4'' be the smallest CIRCLE through X and tangent to ABC, the radius of C_4'' is therefore $h/2 = r(1-r)/2 = R$ (Schoch), and its center is located at



$$x_4''=\tfrac{1}{4}+\tfrac{1}{2}r+\tfrac{1}{4}(2r-1)\sqrt{1+4r-4r^2} \qquad (36)$$

$$y_4''=\tfrac{1}{2}r(1-r). \qquad (37)$$

7. Within each small semicircle of an arbelos, construct arbeloses similar to the original. Then the circles C_5 and C_5' are congruent and have radius R (Schoch). Moreover, connect the midpoints of the arcs and their cusp points to form the RECTANGLES $\square\, EFGH$ and $\square\, E'F'G'H'$. Then these rectangles are similar with respect to the point C_5'' (Schoch). This point lies on the line $B'D'$, and the circle with center C_5'' and radius $C_5''B'$ also has radius R, so C_5'' has coordinates $(\tfrac{1}{2}r(1+3r-2r^2), \tfrac{1}{2}r(1-r))$. The following tables summarized the positions of the rectangle vertices.

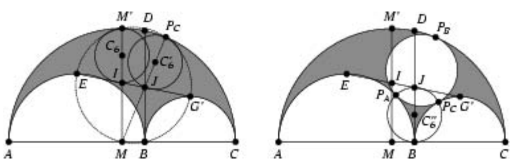
X	Coordinates	X'	Coordinates
E	$(\tfrac{1}{2}r, \tfrac{1}{2}r)$	E'	$(r(2-r), 0)$
F	$(\tfrac{1}{2}r(1+r), \tfrac{1}{2}r(1-r))$	F'	$(\tfrac{1}{2}r(3-r), \tfrac{1}{2}r(1-r))$
G	$(r^2, 0)$	G'	$(\tfrac{1}{2}(1+r), \tfrac{1}{2}(1-r))$
H	$(\tfrac{1}{2}r^2, \tfrac{1}{2}r^2)$	H'	$(\tfrac{1}{2}(1+2r-r^2), \tfrac{1}{2}(1-r)^2)$

8. Let MM' be the PERPENDICULAR BISECTOR of AC, let B be the cusp of the arbelos and D lie above it, let E and G' be the tops of the large and small semicircles, respectively. Let EG' intersect the lines MM' and BD in points I and J, respectively. Then the smallest circle C_6 passing through I and tangent to arc AC at M', the smallest circle C_6' through J and tangent to the outside semicircle at P_C, and the circle C_6'' with diameter JB are all equal to the Archimedean circles (Schoch). The circle C_6'' is called the BANKOFF CIRCLE, and is also the CIRCUMCIRCLE of the point B and tangent points P_A and P_C of the first Pappus circle. The centers of the circles C_6, C_6', and C_6'' are given by

$$x_6=\tfrac{1}{2}$$

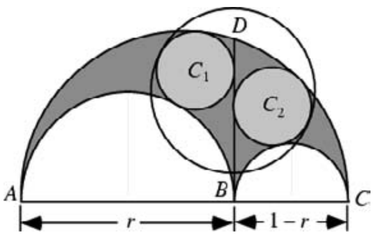
$$y_6=\tfrac{1}{2}(1-r+r^2) \qquad (38)$$

$$x_6' = \frac{r(1-r+2r^2)}{2(1-2r+2r^2)} \tag{39}$$



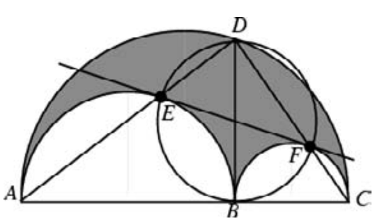
$$y_6' = \frac{r(1-r)(1-r+r^2)}{1-2r+2r^2} \tag{40}$$

$$x_6'' = r \tag{41}$$

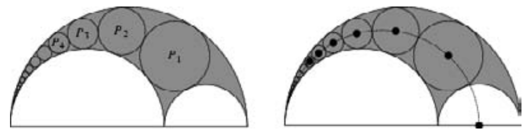


$$y_6'' = \tfrac{1}{2}r(1-r). \tag{42}$$

Rather amazingly, the points E, M, B, G', P_C, D, and M' are CONCYCLIC (Schoch) in a circle with center $((1+2r)/4,\ 1/4)$ and radius



$$R_{EMBG'P_CDM'} = \tfrac{1}{4}\sqrt{2(1-2r+2r^2)}. \tag{43}$$



9. The smallest CIRCUMCIRCLE of the Archimedean circles has an area equal to that of the arbelos.

10. The line tangent to the semicircles AB and BC contains the point E and F which lie on the lines AD and CD, respectively. Furthermore, BD and EF bisect each other, and the points B, D, E, and F are CONCYCLIC.

11. Construct a chain of TANGENT CIRCLES starting with the CIRCLE TANGENT to the two small ones and large one (a so-called PAPPUS CHAIN). The centers of the CIRCLES lie on an ELLIPSE, and the DIAMETER of the nth CIRCLE C_n is $((1/n))$th PERPENDICULAR distance to the base of the SEMICIRCLE. This result is most easily proven using INVERSION, but was known to Pappus, who referred to it as an ancient theorem (Hood 1961, Cadwell 1966, Gardner 1979, Bankoff 1981).

12. If B divides AC in the GOLDEN RATIO ϕ, then the circles in the chain satisfy a number of other special properties (Bankoff 1955).

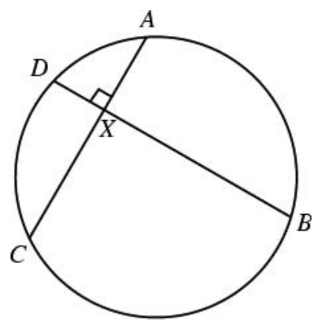
Arborescence

A DIRECTED GRAPH is called an arborescence if, from a given node x known as the ROOT NODE, there is

exactly one elementary path from x to every other node y.



See also Arboricity, Directed Graph, Root Node

Arboricity

Given a graph G, the arboricity is the minimum number of line-disjoint acyclic subgraphs whose union is G.

See also Anarboricity

Arc

In general, any smooth curve joining two points. In particular, any portion (other than the entire curve) of a circle or ellipse. As Archimedes proved, for chords AC and BD which are perpendicular to each other,

$$\text{arc } AB + \text{arc } CD = \text{arc } BC + \text{arc } DA$$

(Wells 1991).
The prefix "arc" is also used to denote the inverse functions of trigonometric functions and hyperbolic functions. Finally, any path through a graph which passes through no vertex twice is called an arc (Gardner 1984, p. 96).

Arc Length

Arc length is defined as the length along a curve,

$$s \equiv \int_a^b |dl|. \tag{1}$$

Defining the line element $ds^2 \equiv |dl|^2$, parameterizing the curve in terms of a parameter t, and noting that ds/dt is simply the magnitude of the velocity with which the end of the radius vector $\mathbf{r}$ moves gives

$$s = \int_a^b ds = \int_a^b \frac{ds}{dt}\, dt = \int_a^b |\mathbf{r}'(t)| dt. \tag{2}$$

In polar coordinates,

$$d\ell = \hat{\mathbf{r}}\, dr + r\hat{\theta}\, d\theta = \left(\frac{dr}{d\theta}\,\hat{\mathbf{r}} + r\hat{\theta}\right) d\theta, \tag{3}$$

so

$$ds = |d\ell| = \sqrt{r^2 + \left(\frac{dr}{d\theta}\right)^2}\, d\theta \tag{4}$$

$$s = \int |d\ell| = \int_{0_1}^{0_2} \sqrt{r^2 + \left(\frac{dr}{d\theta}\right)^2}\, d\theta. \tag{5}$$

In Cartesian coordinates,

$$d\ell = dy\hat{\mathbf{x}} + dy\hat{\mathbf{y}} \tag{6}$$

$$ds = |d\ell . d\ell| = \sqrt{dx^2 + dy^2} = \sqrt{\left(\frac{dy}{dx}\right)^2 + 1}\, dx. \tag{7}$$

Therefore, if the curve is written

$$\mathbf{r}(x) = x\hat{\mathbf{x}} + f(x)\hat{\mathbf{y}}, \tag{8}$$

then

$$s = \int_a^b \sqrt{1 + f'^2(x)}\, dx. \tag{9}$$

If the curve is instead written

$$\mathbf{r}(t) = x(t)\hat{\mathbf{x}} + y(t)\hat{\mathbf{y}}, \tag{10}$$

then

$$s = \int_a^b \sqrt{x'^2(t) + y'^2(t)}\, dt. \tag{11}$$

Or, in three dimensions,

$$\mathbf{r}(t) = x(t)\hat{\mathbf{x}} + y(t)\hat{\mathbf{y}} + z(t)\hat{\mathbf{z}}, \tag{12}$$

so

$$s = \int_a^b \sqrt{x'^2(t) + y'^2(t) + z'^2(t)}\, dt. \tag{13}$$

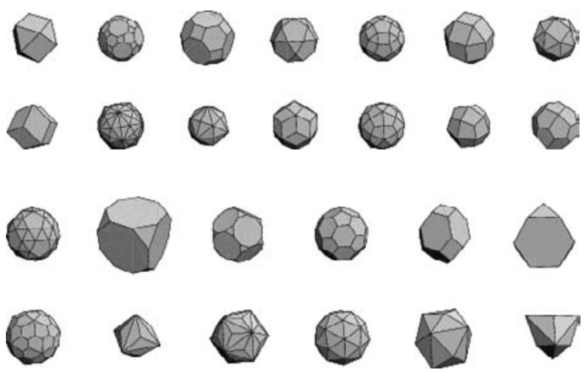
Archimedean Dual



The DUALS of the ARCHIMEDEAN SOLIDS, sometimes called the CATALAN SOLIDS, are given in the following table. Hume (1986) gives exact solutions for the side lengths, angles, and DIHEDRAL ANGLES of the Archimedean duals.

n	ARCHIMEDEAN SOLID	DUAL
1	CUBOCTAHEDRON	RHOMBIC DODECAHEDRON
2	GREAT RHOMBICOSIDODECAHEDRON	DISDYAKIS TRIACONTAHEDRON
3	GREAT RHOMBICUBOCTAHEDRON	DISDYAKIS DODECAHEDRON
4	ICOSIDODECAHEDRON	RHOMBIC TRIACONTAHEDRON
5	SMALL RHOMBICOSIDODECAHEDRON	DELTOIDAL HEXECONTAHEDRON
6	SMALL RHOMBICUBOCTAHEDRON	DELTOIDAL ICOSITETRAHEDRON
7	SNUB CUBE (laevo)	PENTAGONAL ICOSITETRAHEDRON (dextro)
8	SNUB DODECAHEDRON (laevo)	PENTAGONAL HEXECONTAHEDRON (dextro)
9	TRUNCATED CUBE	SMALL TRIAKIS OCTAHEDRON
10	TRUNCATED DODECAHEDRON	TRIAKIS ICOSAHEDRON
11	TRUNCATED ICOSAHEDRON	PENTAKIS DODECAHEDRON
12	TRUNCATED OCTAHEDRON	TETRAKIS HEXAHEDRON
13	TRUNCATED TETRAHEDRON	TRIAKIS TETRAHEDRON

Here are the Archimedean DUALS (Pearce 1978, Holden 1991) displayed in the order listed above (left to right, then continuing to the next row).

Here are the Archimedean solids paired with their DUALS.

Archimedean Solid

The Archimedean solids are convex POLYHEDRA which have a similar arrangement of nonintersecting regular plane CONVEX POLYGONS of two or more different types arranged in the same way about each VERTEX with all sides the same length (Cromwell 1997, pp. 91–2). The Archimedean solids are distinguished from the regular PRISMS and ANTIPRISMS by having very high symmetry, thus excluding solids belonging to a DIHEDRAL GROUP of symmetries (e.g., prisms and antiprisms with unit side lengths) and the ELONGATED SQUARE GYROBICUPOLA (because that surface's symmetry-breaking twist allows vertices "near the equator" and those "in the polar regions" to be distinguished; Cromwell 1997, p. 92). The Archimedean solids are sometimes also referred to as the SEMIREGULAR POLYHEDRA.

Nine of the Archimedean solids can be obtained by TRUNCATION of a PLATONIC SOLID, and two further can be obtained by a second truncation. The remaining two solids, the SNUB CUBE and SNUB DODECAHEDRON, are obtained by moving the faces of a CUBE and DODECAHEDRON outward while giving each face a twist. The resulting spaces are then filled with ribbons of EQUILATERAL TRIANGLES (Wells 1991).

Pugh (1976, p. 25) points out the Archimedean solids are all capable of being circumscribed by a regular TETRAHEDRON so that four of their faces lie on the faces of that TETRAHEDRON. A method of constructing the Archimedean solids using a method known as "expansion" has been enumerated by Stott (Stott 1910; Ball and Coxeter 1987, pp. 139–40).

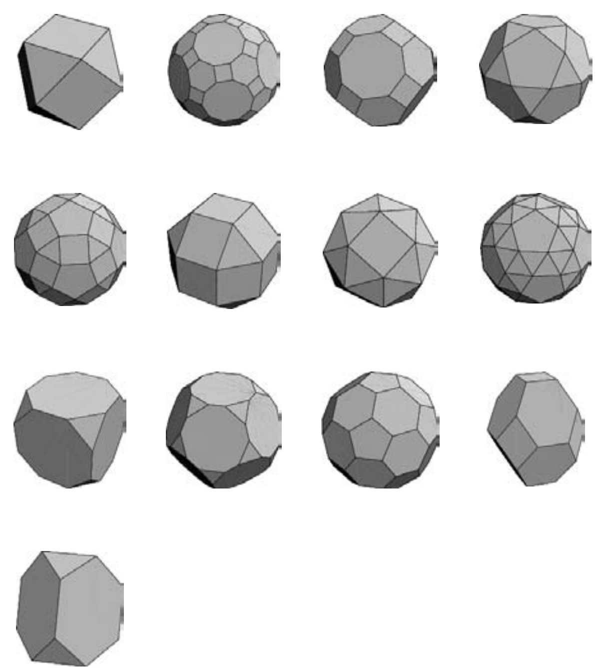
Let the cyclic sequence $S=(p_1, p_2, \ldots p_q)$ represent the degrees of the faces surrounding a vertex (i.e., S is a list of the number of sides of all polygons surrounding any vertex). Then the definition of an Archimedean solid requires that the sequence must be the same for each vertex to within ROTATION and REFLECTION. Walsh (1972) demonstrates that S represents the degrees of the faces surrounding each vertex of a semiregular convex polyhedron or TESSELLATION of the plane IFF

1. $q \geq 3$ and every member of S is at least 3,
2. $\Sigma_{i=1}^{q} \frac{1}{pi} \geq \frac{1}{2} q - 1$, with equality in the case of a plane TESSELLATION, and
3. for every ODD NUMBER $p \in S$, S contains a subsequence (b, p, b).

Condition (1) simply says that the figure consists of two or more polygons, each having at least three sides. Condition (2) requires that the sum of interior angles at a vertex must be equal to a full rotation for the figure to lie in the plane, and less than a full rotation for a solid figure to be convex.

The usual way of enumerating the semiregular polyhedra is to eliminate solutions of conditions (1) and (2) using several classes of arguments and then prove that the solutions left are, in fact, semiregular (Kepler 1864, pp. 116–26; Catalan 1865, pp. 25–2; Coxeter 1940, p. 394; Coxeter *et al.* 1954; Lines 1965,

pp. 202–03; Walsh 1972). The following table gives all possible regular and semiregular polyhedra and tessellations. In the table, 'P' denotes PLATONIC SOLID, 'M' denotes a PRISM or ANTIPRISM, 'A' denotes an Archimedean solid, and 'T' a plane tessellation.



S	Figure	Solid	SCHLÄFLI SYMBOL
(3, 3, 3)	P	TETRAHEDRON	$\{3, 3\}$
(3, 4, 4)	M	Triangular PRISM	$t^{\{2, 3\}}$
(3, 6, 6)	A	TRUNCATED TETRAHEDRON	$t\{3, 3\}$
(3, 8, 8)	A	TRUNCATED CUBE	$t^{\{4, 3\}}$
(3, 10, 10)	A	TRUNCATED DODECAHEDRON	$t^{\{5, 3\}}$
(3, 12, 12)	T	(Plane TESSELLATION)	$t^{\{6, 3\}}$
(4, 4, n)	M	n-gonal PRISM	$t^{\{2, n\}}$
(4, 4, 4)	P	CUBE	$\{4, 3\}$

As shown in the above table, there are exactly 13 Archimedean solids (Walsh 1972, Ball and Coxeter 1987). They are called the CUBOCTAHEDRON, GREAT RHOMBICOSIDODECAHEDRON, GREAT RHOMBICUBOCTAHEDRON, ICOSIDODECAHEDRON, SMALL RHOMBICOSIDODECAHEDRON, SMALL RHOMBICUBOCTAHEDRON, SNUB CUBE, SNUB DODECAHEDRON, TRUNCATED CUBE, TRUNCATED DODECAHEDRON, TRUNCATED ICOSAHEDRON (soccer ball), TRUNCATED OCTAHEDRON, and TRUNCATED TETRAHEDRON. The Archimedean solids satisfy

$$(2\pi - \sigma)V = 4\pi,$$

where σ is the sum of face-angles at a vertex and V is the number of vertices (Steinitz and Rademacher 1934, Ball and Coxeter 1987).

Here are the Archimedean solids shown in alphabetical order (left to right, then continuing to the next row).

The following table lists the symbols for the Archimedean solids (Wenninger 1989, p. 9).

n	Solid	Schläfli symbol	Wythoff symbol	C&R Symbol
1	cuboctahedron	$\left\{\begin{smallmatrix}3\\4\end{smallmatrix}\right\}$	2 2|34 3 4	$(3.4)^2$
2	great rhombicosidodecahedron	$t\left\{\begin{smallmatrix}3\\5\end{smallmatrix}\right\}$	2 3 5 2|34	
3	great rhombicuboctahedron	$t\left\{\begin{smallmatrix}3\\4\end{smallmatrix}\right\}$	2 3 4 2|34	
4	icosidodecahedron	$\left\{\begin{smallmatrix}3\\5\end{smallmatrix}\right\}$	2 2|34 3 5	$(3.5)^2$
5	small rhombicosidodecahedron	$t\left\{\begin{smallmatrix}3\\5\end{smallmatrix}\right\}$	3 5 2|34 2	3.4.5.4
6	small rhombicuboctahedron	$r\left\{\begin{smallmatrix}3\\4\end{smallmatrix}\right\}$	3 4 2|34 2	3.4^3
7	snub cube	$s\left\{\begin{smallmatrix}3\\4\end{smallmatrix}\right\}$	2|34 2 3 4	$3^4.4$
8	snub dodecahedron	$s\left\{\begin{smallmatrix}3\\5\end{smallmatrix}\right\}$	2|34 2 3 5	$3^4.5$
9	truncated cube	$t\{4, 3\}$	2 3 2|34 4	3.8^2
10	truncated dodecahedron	$t\{5, 3\}$	2 3 2|34 5	3.10^2
11	truncated icosahedron	$t\{3, 5\}$	2 5 2|34 3	5.6^2
12	truncated octahedron	$t\{3, 4\}$	2 4 2|34 3	4.6^2
13	truncated tetrahedron	$t\{3, 3\}$	2 3 2|34 3	3.6^2

The following table gives the number of vertices v, edges e, and faces f, together with the number of n-gonal faces f_n for the Archimedean solids.

n	Solid	v	e	f	f_3	f_4	f_5	f_6	f_8	f_{10}
1	cuboctahedron	12	24	14	8	6				
2	great rhombicosidodecahedron	120	180	62		30		20		12
3	great rhombicuboctahedron	48	72	26		12		8	6	
4	icosidodecahedron	30	60	32	20		12			
5	small rhombicosidodecahedron	60	120	62	20	30	12			
6	small rhombicuboctahedron	24	48	26	8	18				
7	snub cube	24	60	38	32	6				
8	snub dodecahedron	60	150	92	80		12			
9	truncated cube	24	36	14	8				6	
10	truncated dodecahedron	60	90	32	20					12
11	truncated icosahedron	60	90	32			12	20		
12	truncated octahedron	24	36	14		6		8		
13	truncated tetrahedron	12	18	8	4			4		

Let r be the inradius of the dual polyhedron (corresponding to the insphere, which touches the faces of the dual solid), ρ be the midradius of both the polyhedron and its dual (corresponding to the midsphere, which touches the edges of both the polyhedron and its duals), and R the circumradius (corresponding to the circumsphere of the solid which touches the vertices of the solid). Since the circumsphere and insphere are dual to each other, they obey the relationship

$$R_r = \rho^2 \tag{1}$$

(Cundy and Rollett 1989, Table II following p. 144). The following tables give the analytic and numerical values of r, ρ, and R for the Archimedean solids with edges of unit length (Coxeter *et al.* 1954; Cundy and Rollett 1989, Table II following p. 144). Hume (1986) gives approximate expressions for the dihedral angles of the Archimedean solid (and exact expressions for their duals).

n	Solid	r	ρ	R
1	cuboctahedron	$\frac{3}{4}$	$\frac{1}{2}\sqrt{3}$	1
2	great rhombicosidodecahedron	$\frac{1}{241}(105+6\sqrt{5}) \times \sqrt{31+12\sqrt{5}}$	$\frac{1}{2}\sqrt{30+12\sqrt{5}}$	$\frac{1}{2}\sqrt{31+12\sqrt{5}}$
3	great rhombicuboctahedron	$\frac{3}{97}(14+\sqrt{2}) \times \sqrt{13+6\sqrt{2}}$	$\frac{1}{2}\sqrt{12+6\sqrt{2}}$	$\frac{1}{2}\sqrt{13+6\sqrt{2}}$
4	icosidodecahedron	$\frac{1}{8}(5+3\sqrt{5})$	$\frac{1}{2}\sqrt{5+2\sqrt{5}}$	$\frac{1}{2}(1+\sqrt{5})$
5	small rhombicosidodecahedron	$\frac{1}{41}(15+2\sqrt{5}) \times \sqrt{11+4\sqrt{5}}$	$\frac{1}{2}\sqrt{10+4\sqrt{5}}$	$\frac{1}{2}\sqrt{11+4\sqrt{5}}$
6	small rhombicuboctahedron	$\frac{1}{17}(6+\sqrt{2}) \times \sqrt{5+2\sqrt{2}}$	$\frac{1}{2}\sqrt{4+2\sqrt{2}}$	$\frac{1}{2}\sqrt{5+2\sqrt{2}}$
7	snub cube	*	*	*
8	snub dodecahedron	*	*	*
9	truncated cube	$\frac{1}{17}(5+2\sqrt{2}) \times \sqrt{7+4\sqrt{2}}$	$\frac{1}{2}(2+\sqrt{2})$	$\frac{1}{2}\sqrt{7+4\sqrt{2}}$
10	truncated dodecahedron	$\frac{5}{488}(17\sqrt{2}+3\sqrt{10}) \times \sqrt{37+15\sqrt{5}}$	$\frac{1}{4}(5+3\sqrt{5})$	$\frac{1}{4}\sqrt{74+30\sqrt{5}}$
11	truncated icosahedron	$\frac{9}{872}(21+\sqrt{5}) \times \sqrt{58+18\sqrt{5}}$	$\frac{3}{4}(1+\sqrt{5})$	$\frac{1}{4}\sqrt{58+18\sqrt{5}}$
12	truncated octahedron	$\frac{9}{20}\sqrt{10}$	$\frac{3}{2}$	$\frac{1}{2}\sqrt{10}$
13	truncated tetrahedron	$\frac{9}{44}\sqrt{22}$	$\frac{3}{4}\sqrt{2}$	$\frac{1}{2}\sqrt{22}$

*The complicated analytic expressions for the circumradii of these solids are given in the entries for the snub cube and snub dodecahedron.

n	Solid	r	ρ	R
1	cuboctahedron	0.75	0.86603	1
2	great rhombicosidodecahedron	3.73665	3.76938	3.80239
3	great rhombicuboctahedron	2.20974	2.26303	2.31761
4	icosidodecahedron	1.46353	1.53884	1.61803

Archimedean Solid Stellation

A large class of POLYHEDRA which includes the DODECADODECAHEDRON and GREAT ICOSIDODECAHEDRON. No complete enumeration (even with restrictive uniqueness conditions) has been worked out. There are at least four stellations of the CUBOCTAHEDRON (Wenninger 1989), although the exact number depends on what type of cells formed by plane intersections are allowed.

There are also many stellations of the Archimedean solid duals. The RHOMBIC DODECAHEDRON has three stellations (Wells 1991, pp. 216–17).

Archimedean Spiral

A SPIRAL with POLAR equation

$$r = a\theta^{1/n}, \quad (1)$$

where r is the radial distance, θ is the polar angle, and n is a constant which determines how tightly the spiral is "wrapped." The CURVATURE of an Archimedean spiral is given by

$$\kappa = \frac{n\theta^{1-1/n}(1+n+n^2\theta^2)}{a(1+n^2\theta^2)^{3/2}}, \quad (2)$$

and the ARC LENGTH by

$$s = a\theta^{1/n}\,{}_2F_1((2n)^{-1}, -\tfrac{1}{2};\ 1+(2n)^{-1};\ -n^2\theta^2), \quad (3)$$

where ${}_2F_1(a, b; c; x)$ is a HYPERGEOMETRIC FUNCTION. Various special cases are given in the following table.

Name	n
LITUUS	-2
HYPERBOLIC SPIRAL	-1
ARCHIMEDES' SPIRAL	1
FERMAT'S SPIRAL	2

If a fly crawls radially outward along a uniformly spinning disk, the curve it traces with respect to a reference frame in which the disk is at rest is an Archimedean spiral (Steinhaus 1999, p. 137). Furthermore, a heart-shaped frame composed of two arcs of an Archimedean spiral which is fixed to a rotating disk converts uniform rotational motion to uniform back-and-forth motion (Steinhaus 1999, pp. 136–37).

Archimedean Spiral Inverse Curve

The INVERSE CURVE of the ARCHIMEDEAN SPIRAL

$$r = a\theta^{1/n}$$

with INVERSION CENTER at the origin and inversion RADIUS k is the ARCHIMEDEAN SPIRAL

$$r = ka\theta^{1/n}.$$

Archimedean Tessellation

TESSELLATION

Archimedean Valuation

A VALUATION for which $|x| \leq 1$ IMPLIES $|1+x| \leq C$ for the constant $C = 1$ (independent of x). Such a VALUATION *does not* satisfy the strong TRIANGLE INEQUALITY

$$|x+y| \leq \max(|x|, |y|).$$

Archimedes Algorithm

Successive application of ARCHIMEDES' RECURRENCE FORMULA gives the Archimedes algorithm, which can be used to provide successive approximations to π (PI). The algorithm is also called the BORCHARDT-PFAFF ALGORITHM. Archimedes obtained the first rigorous approximation of π by CIRCUMSCRIBING and INSCRIBING $n = G \cdot 2^k$-gons on a CIRCLE. From ARCHIMEDES' RECURRENCE FORMULA, the CIRCUMFERENCES a and b of the circumscribed and inscribed POLYGONS are

$$a(n) = 2n\tan\left(\frac{\pi}{n}\right) \quad (1)$$

$$b(n) = 2n\sin\left(\frac{\pi}{n}\right), \quad (2)$$

where

$$b(n) < C = 2\pi r = 2\pi \cdot 1 = 2\pi < a(n). \quad (3)$$

For a HEXAGON, $n = 6$ and

$$a_0 \equiv a(6) = 4\sqrt{3} \quad (4)$$

$$b_0 \equiv b(6) = 6, \quad (5)$$

where $a_k \equiv a(6 \cdot 2^k)$. The first iteration of ARCHIMEDES' RECURRENCE FORMULA then gives

$$a_1 = \frac{2 \cdot 6 \cdot 4\sqrt{3}}{6+4\sqrt{3}} = \frac{24\sqrt{3}}{3+2\sqrt{3}} = 24\left(2-\sqrt{3}\right) \quad (6)$$

$$b_1 = \sqrt{24\left(2-\sqrt{3}\right) \cdot 6} = 12\sqrt{2-\sqrt{3}}$$

$$= 6\left(\sqrt{6} - \sqrt{2}\right). \quad (7)$$

Additional iterations do not have simple closed forms, but the numerical approximations for $k = 0, 1, 2, 3, 4$ (corresponding to 6-, 12-, 24-, 48-, and 96-gons) are

$$3.00000 < \pi < 3.46410 \quad (8)$$

$$3.10583 < \pi < 3.21539 \quad (9)$$

$$3.13263 < \pi < 3.15966 \quad (10)$$

$$3.13935 < \pi < 3.14609 \quad (11)$$

$$3.14103 < \pi < 3.14271. \quad (12)$$

By taking $k = 4$ (a 96-gon) and using strict inequalities to convert irrational bounds to rational bounds at each step, Archimedes obtained the slightly looser result

$$\tfrac{223}{71} = 3.14084\ldots < \pi < \tfrac{22}{7} = 3.14285\ldots. \quad (13)$$

Archimedes' Axiom

An AXIOM actually attributed to Eudoxus (Boyer and Merzbach 1991, pp. 89–0) which states that

$$\frac{a}{b} = \frac{c}{d}$$

IFF the appropriate one of following conditions is satisfied for INTEGERS m and n:

1. If $ma < nb$, then $mc < nd$.
2. If $ma = nb$, then $mc = nd$.
3. If $ma > nb$, then $mc > nd$.

Also known as the continuity axiom or Archimedes' lemma, this axiom survives in the writings of Eudoxus (Boyer and Merzbach 1991). It states that, given two magnitudes having a ratio, one can find a multiple of either which will exceed the other. This principle was the basis for the EXHAUSTION METHOD which Archimedes invented to solve problems of AREA and VOLUME.

Formally, Archimedes' axiom states that if AB and CD are two line segments, then there exist a finite number of points $A_1, A_2, \ldots, A_n$ on $A \cup B$ such that

$$CD \equiv AA_1 \equiv AA_2 \equiv \ldots \equiv A_{n-1}A_n,$$

and B is between A and A_n (Itô 1986, p. 611). A geometry in which Archimedes' lemma does not hold is called a NON-ARCHIMEDEAN GEOMETRY.

Archimedes' Cattle Problem

Also called the BOVINUM PROBLEMA. It is stated as follows: "The sun god had a herd of cattle consisting of bulls and cows, one part of which was white, a second black, a third spotted, and a fourth brown. Among the bulls, the number of white ones was one half plus one third the number of the black greater than the brown; the number of the black, one quarter plus one fifth the number of the spotted greater than the brown; the number of the spotted, one sixth and one seventh the number of the white greater than the brown. Among the cows, the number of white ones was one third plus one quarter of the total black cattle; the number of the black, one quarter plus one fifth the total of the spotted cattle; the number of spotted, one fifth plus one sixth the total of the brown cattle; the number of the brown, one sixth plus one seventh the total of the white cattle. What was the composition of the herd?"

Solution consists of solving the simultaneous DIOPHANTINE EQUATIONS in INTEGERS W, X, Y, Z (the number of white, black, spotted, and brown bulls) and w, x, y, z (the number of white, black, spotted, and brown cows),

$$W = \tfrac{5}{6}X + Z \quad (1)$$

$$X = \tfrac{9}{20}Y + Z \quad (2)$$

$$Y = \tfrac{13}{42}W + Z \quad (3)$$

$$w = \tfrac{7}{12}(X + x) \quad (4)$$

$$x = \tfrac{9}{20}(Y + y) \quad (5)$$

$$y = \tfrac{11}{30}(Z + z) \quad (6)$$

$$z = \tfrac{13}{42}(W + w). \quad (7)$$

The smallest solution in INTEGERS is

$$W = 10,366,482 \quad (8)$$

$$X = 7,460,514 \quad (9)$$

$$Y = 7,358,060 \quad (10)$$

$$Z = 4,149,387 \quad (11)$$

$$w = 7,206,360 \qquad (12)$$

$$x = 4,893,246 \qquad (13)$$

$$y = 3,515,820 \qquad (14)$$

$$z = 5,439,213. \qquad (15)$$

A more complicated version of the problem requires that $W+X$ be a SQUARE NUMBER and $Y+Z$ a TRIANGULAR NUMBER. The solution to this PROBLEM are numbers with 206544 or 206545 digits.

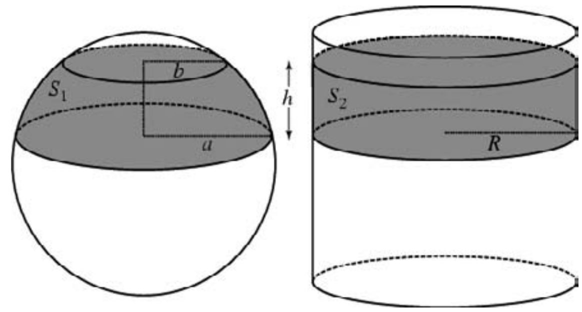
Archimedes' Circles



Draw the PERPENDICULAR LINE from the intersection of the two small SEMICIRCLES in the ARBELOS. The two CIRCLES C_1 and C_2 TANGENT to this line, the large SEMICIRCLE, and each of the two SEMICIRCLES are then congruent and known as Archimedes' circles.

Archimedes' Constant

PI

Archimedes' Hat-Box Theorem

Enclose a SPHERE in a CYLINDER and cut out a SPHERICAL SEGMENT by slicing twice PERPENDICULARLY to the CYLINDER's axis. Then the *lateral* SURFACE AREA of the SPHERICAL SEGMENT S_1 is equal to the *lateral* SURFACE AREA cut out of the CYLINDER S_2 by the same slicing planes, i.e.,

$$S \equiv S_1 = S_2 = 2\pi Rh,$$

where R is the RADIUS of the CYLINDER (and tangent SPHERE) and h is the height of the cylindrical (and spherical) segment.

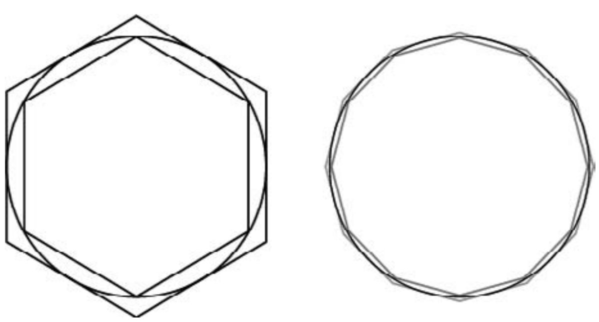
Archimedes' Postulate



ARCHIMEDES' LEMMA

Archimedes' Problem

Cut a SPHERE by a PLANE in such a way that the VOLUMES of the SPHERICAL SEGMENTS have a given RATIO.

See also ARCHIMEDES' HAT-BOX THEOREM, SPHERICAL SEGMENT

Archimedes' Recurrence Formula

Let a_n and b_n be the PERIMETERS of the CIRCUMSCRIBED and INSCRIBED n-gon and a_{2n} and b_{2n} the PERIMETERS of the CIRCUMSCRIBED and INSCRIBED $2n$-gon. Then

$$a_{2n} = \frac{2a_n b_n}{a_n + b_n} \tag{1}$$

$$b_{2n} = \sqrt{a_{2n} b_n}. \tag{2}$$

The first follows from the fact that side lengths of the POLYGONS on a CIRCLE of RADIUS $r = 1$ are

$$s_R = 2\tan\left(\frac{\pi}{n}\right) \tag{3}$$

$$s_r = 2\sin\left(\frac{\pi}{n}\right), \tag{4}$$

so

$$a_n = 2n\tan\left(\frac{\pi}{n}\right) \tag{5}$$

$$b_n = 2n\sin\left(\frac{\pi}{n}\right). \tag{6}$$

But

$$\frac{2a_n b_n}{a_n + b_n} = \frac{2 \cdot 2n\tan\left(\frac{\pi}{n}\right) \cdot 2n\sin\left(\frac{\pi}{n}\right)}{2n\tan\left(\frac{\pi}{n}\right) + 2n\sin\left(\frac{\pi}{n}\right)}$$
$$= 4n\frac{\tan\left(\frac{\pi}{n}\right)\sin\left(\frac{\pi}{n}\right)}{\tan\left(\frac{\pi}{n}\right) + \sin\left(\frac{\pi}{n}\right)}. \tag{7}$$

Using the identity

$$\tan\left(\tfrac{1}{2}x\right) = \frac{\tan x \sin x}{\tan x + \sin x} \tag{8}$$

then gives

$$\frac{2a_n b_n}{a_n + b_n} = 4n\tan\left(\tfrac{\pi}{2n}\right) = a_{2n}. \tag{9}$$

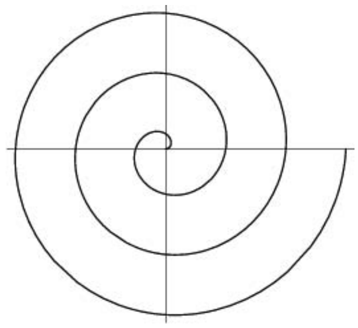
The second follows from

$$\sqrt{a_{2n} b_n} = \sqrt{4n\tan\left(\frac{\pi}{2n}\right) \cdot 2n\sin\left(\frac{\pi}{n}\right)} \tag{10}$$

Using the identity

$$\sin x = 2\sin\left(\tfrac{1}{2}x\right)\cos\left(\tfrac{1}{2}x\right) \tag{11}$$

gives



$$\sqrt{a_{2n} b_n} = 2n\sqrt{2\tan\left(\frac{x}{2n}\right) \cdot 2\sin\left(\frac{\pi}{2n}\right)\cos\left(\frac{\pi}{2n}\right)}$$
$$= 4n\sqrt{\sin^2\left(\frac{\pi}{2n}\right)} = 4n\sin\left(\frac{\pi}{2n}\right) = b_{2n}. \tag{12}$$

Successive application gives the ARCHIMEDES ALGORITHM, which can be used to provide successive approximations to PI (π).

Archimedes' Spiral

An ARCHIMEDEAN SPIRAL with POLAR equation

$$r = a\theta.$$

This spiral was studied by Conon, and later by Archimedes in *On Spirals* about 225 BC. Archimedes was able to work out the lengths of various tangents to the spiral.

Archimedes' spiral can be used for COMPASS and STRAIGHTEDGE division of an ANGLE into n parts (including ANGLE TRISECTION) and can also be used for CIRCLE SQUARING. In addition, the curve can be used as a cam to convert uniform circular motion into uniform linear motion (Steinhaus 1983, p. 137; Brown). The cam consists of one arch of the spiral above the x-AXIS together with its reflection in the x-AXIS. Rotating this with uniform angular velocity about its center will result in uniform linear motion of the point where it crosses the y-AXIS.

Area

The area of a surface is the amount of material needed to "cover" it completely. The area of a triangle is given by

$$A_\Delta = \tfrac{1}{2} lh, \quad (1)$$

where l is the base length and h is the height, or by Heron's formula

$$A_\Delta = \sqrt{s(s-a)(s-b)(s-c)}, \quad (2)$$

where the side lengths are a, b, and c and s the semiperimeter. The area of a rectangle is given by

$$A_{\text{rectangle}} = ab, \quad (3)$$

where the sides are length a and b. This gives the special case of

$$A_{\text{square}} = a^2 \quad (4)$$

for the square. The area of a regular polygon with n sides and side length s is given by

$$A_{n-\text{gon}} = \tfrac{1}{4} ns^2 \cot\left(\frac{\pi}{n}\right). \quad (5)$$

Calculus and, in particular, the integral, are powerful tools for computing the area between a curve $f(x)$ and the x-axis over an interval $[a, b]$, giving

$$A = \int_a^b f(x)\,dx. \quad (6)$$

The area of a polar curve with equation $r = r(\theta)$ is

$$A = \tfrac{1}{2} \int r^2\,d\theta. \quad (7)$$

Written in Cartesian coordinates, this becomes

$$A = \frac{1}{2} \int \left(x\,\frac{dy}{dt} - y\,\frac{dx}{dt}\right) dt \quad (8)$$

$$= \frac{1}{2} \int (x\,dy - y\,dx). \quad (9)$$

For the area of special surfaces or regions, see the entry for that region. The generalization of area to 3-D is called volume, and to higher dimensions is called content.

Area Element

The area element for a surface with Riemannian metric

$$ds^2 = E\,du^2 + 2F\,du\,dv + G\,dv^2$$

is

$$dA = \sqrt{EG - F^2}\,du \wedge dv,$$

where $du \wedge dv$ is the wedge product.

See also Area, Line Element, Riemannian Metric, Volume Element

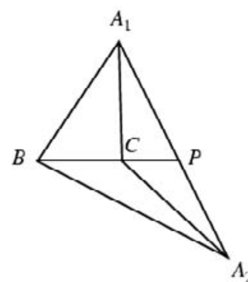
References

Gray, A. "The Intuitive Idea of Area on a Surface." §15.3 in *Modern Differential Geometry of Curves and Surfaces with Mathematica, 2nd ed.* Boca Raton, FL: CRC Press, pp. 351–53, 1997.

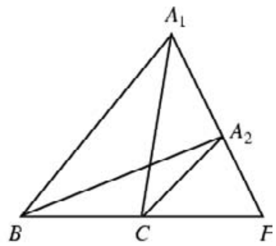
Area Integral

A double integral over three coordinates giving the area within some region R,

$$A = \int\int_R dx\,dy.$$



If a plane curve is given by $y = f(x)$, then the area between the curve and the x-axis from $x = a$ to $x = b$ is given by



$$A = \int_a^b f(x)dx.$$

See also Integral, Line Integral, Lusin Area Integral, Multiple Integral, Surface Integral, Volume Integral

Area Principle

There are at least two results known as "the area principle."

The geometric area principle states that

$$\frac{|A_1P|}{|A_2P|} = \frac{|A_1BC|}{|A_2BC|}. \qquad (1)$$

This can also be written in the form

$$\left[\frac{|A_1P|}{|A_2P|}\right] = \left[\frac{|A_1BC|}{|A_2BC|}\right], \qquad (2)$$

where

$$\left[\frac{AB}{CD}\right] \qquad (3)$$

is the ratio of the lengths $[A, B]$ and $[C, D]$ for $AB\|CD$ with a PLUS or MINUS SIGN depending on if these segments have the same or opposite directions, and

$$\left[\frac{ABC}{DEF}\right] \qquad (4)$$

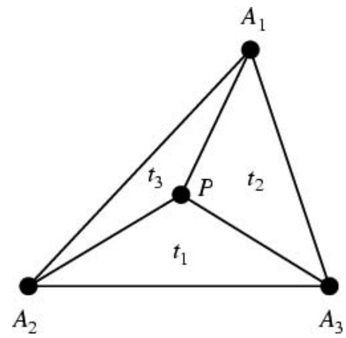
is the RATIO of signed AREAS of the TRIANGLES. Grünbaum and Shepard (1995) show that CEVA'S THEOREM, HOEHN'S THEOREM, and MENELAUS' THEOREM are the consequences of this result.

The area principle of complex analysis states that if f is a SCHLICHT FUNCTION and if

$$h(z) = \frac{1}{f(z)} = \frac{1}{z} + \sum_{j=0}^{\infty} b_j z^j, \qquad (5)$$

then

$$\sum_{j=1}^{\infty} j|b_j|^2 \leq 1 \qquad (6)$$



(Krantz 1999, p. 150).

See also CEVA'S THEOREM, HOEHN'S THEOREM, MENELAUS' THEOREM, SCHLICHT FUNCTION, SELF-TRANSVERSALITY THEOREM

Krantz, S. G. "Schlicht Functions." §12.1.1 in *Handbook of Complex Analysis.* Boston, MA: Birkhäuser, p. 149, 1999.

Areal Coordinates

BARYCENTRIC COORDINATES (t_1, t_2, t_3) normalized so that they become the AREAS of the TRIANGLES PA_1A_2, PA_1A_3, and PA_2A_3, where P is the point whose coordinates have been specified, *normalized by the area of the original triangle* $\Delta A_1A_2A_3$. This is equivalent to application of the normalization relation

$$t_1 + t_2 + t_3 = 1$$

(Coxeter 1969, p. 218).

See also BARYCENTRIC COORDINATES, TRILINEAR COORDINATES

References

Coxeter, H. S. M. *Introduction to Geometry, 2nd ed.* New York: Wiley, p. 218, 1969.

Area-Preserving Map

A MAP F from $\mathbb{R}^n$ to $\mathbb{R}^n$ is AREA-preserving if

$$m(F(A)) = m(A)$$

for every subregion A of $\mathbb{R}^n$, where $m(A)$ is the n-D MEASURE of A. A linear transformation is AREA-preserving if its corresponding DETERMINANT is equal to 1.

See also CONFORMAL MAP, SYMPLECTIC MAP

Arf Invariant

A LINK invariant which always has the value 0 or 1. A KNOT has ARF INVARIANT 0 if the KNOT is "pass equivalent" to the UNKNOT and 1 if it is pass equivalent to the TREFOIL KNOT. If K_+, K_-, and L are projections which are identical outside the region of the crossing diagram, and K_+ and K_- are KNOTS while l is a 2-component LINK with a nonintersecting crossing diagram where the two left and right strands belong to the different LINKS, then

$$a(K_+) = a(K_-) + l(L_1, L_2), \qquad (1)$$

where l is the LINKING NUMBER of L_1 and L_2. The Arf invariant can be determined from the ALEXANDER POLYNOMIAL or JONES POLYNOMIAL for a KNOT. For Δ_K the ALEXANDER POLYNOMIAL of K, the Arf invariant is given by

$$\Delta_K(-1) \equiv \begin{cases} 1 \pmod 8 & \text{if } \mathrm{Arf}(K) = 0 \\ 5 \pmod 8 & \text{if } \mathrm{Arf}(K) = 1 \end{cases} \quad (2)$$

(Jones 1985). For the JONES POLYNOMIAL W_K of a KNOT K,

$$\mathrm{Arf}(K) = W_K(i) \quad (3)$$

(Jones 1985), where I is the IMAGINARY NUMBER.

Arg

ARGUMENT (COMPLEX NUMBER)

Argand Diagram

A plot of COMPLEX NUMBERS as points

$$z = x + iy$$

using the X-AXIS as the REAL AXIS and Y-AXIS as the IMAGINARY AXIS. An Argand diagram is also called the COMPLEX PLANE or ARGAND PLANE. The Argand plane was described by C. Wessel prior to Argand.

See also COMPLEX PLANE, IMAGINARY NUMBER, REAL NUMBER

References

Argand, R. *Essai sur une manière de représenter les quantités imaginaires dans les constructions géométriques.* Paris: Albert Blanchard, 1971. Reprint of the 2nd ed., published by G. J. Hoel in 1874. First edition published Paris, 1806.

Argand Plane

ARGAND DIAGRAM

Argoh's Conjecture

Let B_k be the kth BERNOULLI NUMBER. Then does

$$nB_{n-1} \equiv -1 \pmod n$$

IFF n is PRIME? For example, for $n = 1, 2, \ldots, nB_{n-1} \pmod n$ is 0, -1, -1, 0, -1, 0, -1, 0, -3, 0, -1, ... (Sloane's A046094). There are no counterexamples less than $n = 5,\ 600$. Any counterexample to Argoh's conjecture would be a contradiction to GIUGA'S CONJECTURE, and vice versa.

See also BERNOULLI NUMBER, GIUGA'S CONJECTURE

References

Borwein, D.; Borwein, J. M.; Borwein, P. B.; and Girgensohn, R. "Giuga's Conjecture on Primality." *Amer. Math. Monthly* **103**, 40–0, 1996.

Argument (Complex Number)

A COMPLEX NUMBER z may be REPRESENTED AS

$$z \equiv x + iy = |z|e^{i\theta}, \quad (1)$$

where $|z|$ is called the MODULUS of z, and θ is called the argument (or PHASE) and is given by

$$\arg(x + iy) \equiv \tan^{-1}\left(\frac{y}{x}\right). \quad (2)$$

Here, θ, sometimes also denoted ϕ, corresponds to the counterclockwise ANGLE from the POSITIVE REAL AXIS, i.e., the value of θ such that $x = \cos\theta$ and $y = \sin\theta$. The special kind of INVERSE TANGENT used here takes into account the quadrant in which z lies and is returned by the FORTRAN command ATAN2(X,Y) and the *Mathematica* command ArcTan[x, y], and is often restricted to the range $-\pi < \theta \le \pi$. In the degenerate case when $x = 0$,

$$\phi = \begin{cases} -\frac{1}{2}\pi & \text{if } y < 0 \\ \text{undefined} & \text{if } y = 0 \\ \frac{1}{2}\pi & \text{if } y > 0. \end{cases} \quad (3)$$

From the definition of the argument,

$$\begin{aligned} \arg(zw) &= \arg(|z|e^{i\theta_z}|w|e^{i\theta_w}) = \arg(e^{i\theta_z}e^{i\theta_w}) \\ &= \arg\left[e^{i(\theta_z+\theta_w)}\right] = \arg(z) + \arg(w). \end{aligned} \quad (4)$$

Extending this procedure gives

$$\arg(z^n) = n \arg(z). \quad (5)$$

The argument of a COMPLEX NUMBER is sometimes called the PHASE.

Argument (Elliptic Integral)

Given an AMPLITUDE ϕ in an ELLIPTIC INTEGRAL, the argument u is defined by the relation

$$\phi \equiv am\ u.$$

See also AMPLITUDE, ELLIPTIC INTEGRAL

Argument (Function)

An argument of a FUNCTION $f(x_1, \ldots, x_n)$ is one of the n parameters on which the function's value depends. For example, the SINE $\sin x$ is a one-argument function, the BINOMIAL COEFFICIENT $\binom{n}{m}$ is a two-argument function, and the HYPERGEOMETRIC FUNCTION $2F_1(a, b; c; z)$ is a four-argument function.

Argument Addition Relation

A mathematical relationship relating $f(x+y)$ to $f(x)$ and $f(y)$.

See also ARGUMENT MULTIPLICATION RELATION, RECURRENCE RELATION, REFLECTION RELATION, TRANSLATION RELATION

Argument Multiplication Relation

A mathematical relationship relating $f(nx)$ to $f(x)$ for INTEGER n.

See also ARGUMENT ADDITION RELATION, RECURRENCE RELATION, REFLECTION RELATION, TRANSLATION RELATION

Argument Principle

If $f(z)$ is MEROMORPHIC in a region R enclosed by a CONTOUR γ, let N be the number of COMPLEX ROOTS of $f(z)$ in γ, and P be the number of POLES in γ, then

$$N - P = \frac{1}{2\pi i}\int_\gamma \frac{f'(z)\,dz}{f(z)}$$

Defining $w \equiv f(z)$ and $\sigma \equiv f(\gamma)$ gives

$$N - P = \frac{1}{2\pi i}\int_\sigma \frac{dw}{w}.$$

Argument Variation

VARIATION OF ARGUMENT

Aristotle's Wheel Paradox

A PARADOX mentioned in the Greek work *Mechanica,* dubiously attributed to Aristotle. Consider the above diagram depicting a wheel consisting of two concentric CIRCLES of different DIAMETERS (a wheel within a wheel). there is a 1:1 correspondence of points on the large CIRCLE with points on the small CIRCLE, so the wheel should travel the same distance regardless of whether it is rolled from left to right on the top straight line or on the bottom one. this seems to imply that the two CIRCUMFERENCES of different sized CIRCLES are equal, which is impossible.

The fallacy lies in the assumption that a 1:1 correspondence of points means that two curves must have the same length. In fact, the CARDINALITIES of points in a LINE SEGMENT of any length (or even an INFINITE LINE, a PLANE, a 3-D SPACE, or an infinite dimensional EUCLIDEAN SPACE) are all the same: $\aleph_1$ (ALEPH-1), so the points of any of these can be put in a ONE-TO-ONE correspondence with those of any other.

Arithmetic

The branch of mathematics dealing with INTEGERS or, more generally, numerical computation. Arithmetical operations include ADDITION, CONGRUENCE calculation, DIVISION, FACTORIZATION, MULTIPLICATION, POWER computation, ROOT EXTRACTION, and SUBTRACTION. Arithmetic was part of the QUADRIVIUM taught in medieval universities.

The FUNDAMENTAL THEOREM OF ARITHMETIC, also called the UNIQUE FACTORIZATION THEOREM, states that any POSITIVE INTEGER can be represented in exactly one way as a PRODUCT of PRIMES.

The LÖWENHEIM-SKOLEM THEOREM, which is a fundamental result in MODEL THEORY, establishes the existence of "nonstandard" models of arithmetic.

Arithmetic Mean

For a CONTINUOUS DISTRIBUTION FUNCTION, the arithmetic mean of the population, denoted μ, $\tilde{x}$, $\langle x\rangle$, or $A(x)$, is given by

$$\mu=\langle f(x)\rangle\equiv\int_{-\infty}^{\infty}P(x)f(x)\,dx, \tag{1}$$

where $\langle x\rangle$ is the EXPECTATION VALUE. For a DISCRETE DISTRIBUTION,

$$\mu=\langle f(x)\rangle\equiv\frac{\sum_{n=0}^{N}P(x_n)f(x_n)}{\sum_{n=0}^{N}P(x_n)}=\sum_{n=0}^{N}P(x_n)f(x_n). \tag{2}$$

The population mean satisfies

$$\langle f(x)+g(x)\rangle=\langle f(x)\rangle+\langle g(x)\rangle \tag{3}$$

$$\langle cf(x)\rangle=c\langle f(x)\rangle, \tag{4}$$

and

$$\langle f(x)g(y)\rangle=\langle f(x)\rangle\ \langle g(y)\rangle \tag{5}$$

if x and y are INDEPENDENT STATISTICS. The "sample mean," which is the mean estimated from a statistical sample, is an UNBIASED ESTIMATOR for the population mean.

For small samples, the mean is more efficient than the MEDIAN and approximately $\pi/2$ less (Kenney and Keeping 1962, p. 211). A general expression which often holds approximately is

$$\text{mean}-\text{mode}\approx 3(\text{mean}-\text{median}). \tag{6}$$

Given a set of samples $\{x_i\}$, the arithmetic mean is

$$A(x)\equiv\tilde{x}\equiv\mu\equiv\langle x\rangle=\frac{1}{N}\sum_{i=1}^{N}x_i. \tag{7}$$

Hoehn and Niven (1985) show that

$$\begin{aligned}&A(a_1+c,\ a_2+c,\ \ldots,\ a_n+c)\\&\quad=c+A(a_1,\ a_2,\ \ldots,\ a_n)\end{aligned} \tag{8}$$

for any POSITIVE constant c. For positive arguments, the arithmetic mean satisfies

$$A\geq G\geq H, \tag{9}$$

where G is the GEOMETRIC MEAN and H is the HARMONIC MEAN (Hardy *et al.* 1952; Mitrinovic 1970; Beckenbach and Bellman 1983; Bullen *et al.* 1988; Mitrinovic *et al.* 1993; Alzer 1996). This can be shown as follows. For $a,\ b>0$,

$$\left(\frac{1}{\sqrt{a}}-\frac{1}{\sqrt{b}}\right)^2\geq 0 \tag{10}$$

$$\frac{1}{a}-\frac{2}{\sqrt{ab}}+\frac{1}{b}\geq 0 \tag{11}$$

$$\frac{1}{a}+\frac{1}{b}\geq\frac{2}{\sqrt{ab}} \tag{12}$$

$$\sqrt{ab}\geq\frac{2}{\frac{1}{a}+\frac{1}{b}} \tag{13}$$

$$G\geq H, \tag{14}$$

with equality IFF $b=a$. To show the second part of the inequality,

$$(\sqrt{a}-\sqrt{b})^2=a-2\sqrt{ab}+b\geq 0 \tag{15}$$

$$\frac{a+b}{2}\geq\sqrt{ab} \tag{16}$$

$$A\geq G, \tag{17}$$

with equality IFF $a=b$. Combining (14) and (17) then gives (9).

Given n independent random GAUSSIAN DISTRIBUTED variates x_i, each with population mean $\mu_i = \mu$ and VARIANCE $\sigma_i^2 = \sigma^2$,

$$\tilde{x} \equiv \tfrac{1}{N} \sum_{i=1}^{N} x_i \tag{18}$$

$$\langle x \rangle = \frac{1}{N} \left\langle \sum_{i=1}^{N} x_i \right\rangle = \frac{1}{N} \sum_{i=1}^{N} \langle x_i \rangle$$

$$= \frac{1}{N} \sum_{i=1}^{N} \mu = \frac{1}{N}(N\mu) = \mu, \tag{19}$$

so the sample mean is an UNBIASED ESTIMATOR of population mean. However, the distribution of $\tilde{x}$ depends on the sample size. For large samples, $\tilde{x}$ is approximately NORMAL. For small samples, STUDENT'S T-DISTRIBUTION should be used.

The VARIANCE of the sample mean is independent of the distribution.

$$\operatorname{var}(\tilde{x}) = \operatorname{var}\left(\frac{1}{n} \sum_{i=1}^{N} x_i\right) = \frac{1}{N^2} \operatorname{var}\left(\sum_{i=1}^{N} x_i\right)$$

$$= \frac{1}{N^2} \sum_{i=1}^{n} \operatorname{var}(x_i) = \left(\frac{1}{N^2}\right) \sum_{i=1}^{N} \sigma^2 = \frac{\sigma^2}{N}. \tag{20}$$

From K-STATISTIC for a GAUSSIAN DISTRIBUTION, the UNBIASED ESTIMATOR for the VARIANCE is given by

$$\sigma^2 = \frac{N}{N-1} s^2, \tag{21}$$

where

$$s \equiv \frac{1}{N} \sum_{i=1}^{N} (x_i - \bar{x})^2, \tag{22}$$

so

$$\operatorname{var}(\tilde{x}) = \frac{s^2}{N-1}. \tag{23}$$

The SQUARE ROOT of this,

$$\sigma_x = \frac{s}{\sqrt{N-1}}, \tag{24}$$

is called the STANDARD ERROR.

$$\operatorname{var}(\tilde{x}) \equiv \langle \tilde{x}^2 \rangle - \langle \tilde{x} \rangle^2, \tag{25}$$

so

$$\langle \tilde{x}^2 \rangle = \operatorname{var}(\tilde{x}) + (\tilde{x})^2 = \frac{\sigma^2}{N} + \mu^2. \tag{26}$$

Arithmetic Progression

ARITHMETIC SEQUENCE

Arithmetic Sequence

A SEQUENCE of n numbers $\{d_0 + kd\}_{k=0}^{n-1}$ such that the differences between successive terms is a constant d.

See also ARITHMETIC SERIES, BAUDET'S CONJECTURE, NONARITHMETIC PROGRESSION SEQUENCE, SEQUENCE, SZEMERÉDI'S THEOREM

Arithmetic Series

An arithmetic series is the SUM of a SEQUENCE $\{a_k\}$, $k = 1, 2, \ldots$, in which each term is computed from the previous one by adding (or subtracting) a constant d. Therefore, for $k > 1$,

$$a_k = a_{k-1} + d = a_{k-2} + 2d = \ldots = a_1 + d(k-1). \tag{1}$$

The sum of the sequence of the first n terms is then given by

$$S_n \equiv \sum_{k=1}^{n} a_k = \sum_{k=1}^{n} [a_1 + (k-1)d] = na_1 + d \sum_{k=1}^{n} (k-1)$$

$$= na_1 + d \sum_{k=2}^{n} (k-1)$$

$$= na_1 + d\sum_{k=1}^{n-1} k \qquad (2)$$

Using the SUM identity

$$\sum_{k=1}^{n} k = \tfrac{1}{2}n(n+1) \qquad (3)$$

then gives

$$S_n = na_1 + \tfrac{1}{2}dn(n-1) = \tfrac{1}{2}n[2a_i + d(n-1)]. \qquad (4)$$

Note, however, that

$$a_1 + an = a_1 + [a_1 + d(n-1)] = 2a_1 + d(n-1), \qquad (5)$$

so

$$S_n = \tfrac{1}{2}\, n(a_1 + a_n), \qquad (6)$$

or n times the AVERAGE of the first and last terms! This is the trick Gauss used as a schoolboy to solve the problem of summing the INTEGERS from 1 to 100 given as busy-work by his teacher. While his classmates toiled away doing the ADDITION longhand, Gauss wrote a single number, the correct answer

$$\tfrac{1}{2}(100)(1+100) = 50 \cdot 101 = 5050 \qquad (7)$$

on his slate (Burton 1989, pp. 80–1; Hoffman 1998, p. 207). When the answers were examined, Gauss's proved to be the only correct one.

Arithmetical Function

INTEGER FUNCTION

Arithmetic-Geometric Mean

The arithmetic-geometric mean (often abbreviated AGM) $M(a, b)$ of two numbers a and b is defined by starting with $a_0 \equiv a$ and $b_0 \equiv b$, then iterating

$$a_{n+1} = \tfrac{1}{2}(a_n + b_n) \qquad (1)$$

$$b_{n+1} = \sqrt{a_n b_n} \qquad (2)$$

until $a_n = b_n$. a_n and b_n converge towards each other since

$$a_{n+1} - b_{n+1} = \tfrac{1}{2}(a_n + b_n) - \sqrt{a_n b_n} = \frac{a_n - 2\sqrt{a_n b_n} + b_n}{2}. \qquad (3)$$

But $\sqrt{b_n} < \sqrt{a_n}$, so

$$2b_n < 2\sqrt{a_n b_n}. \qquad (4)$$

Now, add $a_n - b_n - 2\sqrt{a_n b_n}$ to each side

$$a_n + b_n - 2\sqrt{a_n b_n} < a_n - b_n, \qquad (5)$$

so

$$a_{n+1} - b_{n+1} < \tfrac{1}{2}(a_n - b_n). \qquad (6)$$

The AGM is very useful in computing the values of complete ELLIPTIC INTEGRALS and can also be used for finding the INVERSE TANGENT. In terms of the complete ELLIPTIC INTEGRAL OF THE FIRST KIND $K(k)$,

$$M(a, b) = \frac{(a+b)\pi}{4K\left(\frac{a-b}{a+b}\right)}. \qquad (7)$$

The special value $1/M(1, \sqrt{2})$ is called GAUSS'S CONSTANT.

The AGM has the properties

$$\lambda M(a, b) = M(\lambda a, \lambda b) \qquad (8)$$

$$M(a, b) = M\left(\tfrac{1}{2}(a+b), \sqrt{ab}\right) \qquad (9)$$

$$M(1, \sqrt{1-x^2}) = M(1+x, 1-x) \qquad (10)$$

$$M(1, b) = \frac{1+b}{2}\, M\left(1, \frac{2\sqrt{b}}{1+b}\right). \qquad (11)$$

The Legendre form is given by

$$M(1, x) = \prod_{n=0}^{\infty} \tfrac{1}{2}(1+k_n), \qquad (12)$$

where $k_0 \equiv x$ and

$$k_{n+1} \equiv \frac{2\sqrt{k_n}}{1+k_n}. \qquad (13)$$

Solutions to the differential equation

$$(x^3 - x)\frac{d^2y}{dx^2} + (3x^2 - 1)\frac{dy}{dx} + xy = 0 \qquad (14)$$

are given by $[M(1+x, 1-x)]^{-1}$ and $[M(1, x)]^{-1}$.

A generalization of the ARITHMETIC-GEOMETRIC MEAN is

$$I_p(a,\ b) = \int_0^\infty \frac{x^{p-2}\,dx}{(x^p + a^p)^{1/p}(x^p + b^p)^{(p-1)/p}} \qquad (15)$$

which is related to solutions of the differential equation

$$x(1-x^p)Y'' + [1-(p+1)x^p]Y' - (p-1)x^{p-1}Y = 0. \quad (16)$$

When $p = 2$ or $p = 3$, there is a modular transformation for the solutions of (16) that are bounded as $x \to 0$. Letting $J_p(x)$ be one of these solutions, the transformation takes the form

$$J_p(\lambda) = \mu J_p(x), \qquad (17)$$

where

$$\lambda = \frac{1-u}{1+(p-1)u} \qquad (18)$$

$$\mu = \frac{1+(p-1)u}{p} \qquad (19)$$

and

$$x^p + u^p = 1. \qquad (20)$$

The case $p = 2$ gives the ARITHMETIC-GEOMETRIC MEAN, and $p = 3$ gives a cubic relative discussed by Borwein and Borwein (1990, 1991) and Borwein (1996) in which, for $a,\ b > 0$ and $I(a,\ b)$ defined by

$$I(a,\ b) = \int_0^\infty \frac{t\,dt}{[(a^3 + t^3)(b^3 + t^3)^2]^{1/3}}, \qquad (21)$$

$$I(a,\ b) = I\left(\frac{a+2b}{3}, \left[\frac{b}{3}(a^2 + ab + b^2)\right]\right) \qquad (22)$$

For iteration with $a_0 = a$ and $b_0 = b$ and

$$a_{n+1} = \frac{a_n + 2b_n}{3} \qquad (23)$$

$$b_{n+1} = \frac{b_n}{3}(a_n^2 + a_n b_n + b_n^2), \qquad (24)$$

$$\lim_{n\to\infty} a_n = \lim_{n\to\infty} b_n = \frac{I(1,\ 1)}{I(a,\ b)}. \qquad (25)$$

Modular transformations are known when $p = 4$ and $p = 6$, but they do not give identities for $p = 6$ (Borwein 1996).

Arithmetic-Harmonic Mean

Let

$$a_{n+1} = \tfrac{1}{2}(a_n + b_n) \qquad (1)$$

$$b_{n+1} = \frac{2a_n b_n}{a_n + b_n}. \qquad (2)$$

Then

$$A(a_0,\ b_0) = \lim_{n\to\infty} a_n = \lim_{n\to\infty} b_n \sqrt{a_0 b_0}, \qquad (3)$$

which is just the GEOMETRIC MEAN.

Arithmetic-Logarithmic-Geometric Mean Inequality

$$\frac{a+b}{2} > \frac{b-a}{\ln b - \ln a} > \sqrt{ab}.$$

Arnold Tongue

Consider the CIRCLE MAP. If K is NONZERO, then the motion is periodic in some FINITE region surrounding each rational Ω. This execution of periodic motion in response to an irrational forcing is known as MODE LOCKING. If a plot is made of K versus Ω with the regions of periodic MODE-LOCKED parameter space plotted around rational Ω values (the WINDING NUMBERS), then the regions are seen to widen upward from 0 at $K = 0$ to some FINITE width at $K = 1$. The region surrounding each RATIONAL NUMBER is known as an ARNOLD TONGUE.

At $K = 0$, the Arnold tongues are an isolated set of MEASURE zero. At $K = 1$, they form a general CANTOR SET of dimension $d = 0.8700 \pm 3.7 \times 10^{-4}$ (Rasband 1990, p. 131). In general, an Arnold tongue is defined as a resonance zone emanating out from RATIONAL NUMBERS in a two-dimensional parameter space of variables.

Rasband, S. N. *Chaotic Dynamics of Nonlinear Systems.* New York: Wiley, pp. 130–31, 1990.

Arnold's Cat Map

The best known example of an ANOSOV DIFFEOMORPHISM. It is given by the TRANSFORMATION

$$\begin{bmatrix} x_n+1 \\ y_n+1 \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 1 & 2 \end{bmatrix} \begin{bmatrix} x_n \\ y_n \end{bmatrix}, \tag{1}$$

where x_{n+1} and y_{n+1} are computed mod 1. The Arnold cat mapping is non-Hamiltonian, nonanalytic, and mixing. However, it is AREA-PRESERVING since the DETERMINANT is 1. The LYAPUNOV CHARACTERISTIC EXPONENTS are given by

$$\begin{vmatrix} 1-\sigma & 1 \\ 1 & 2-\sigma \end{vmatrix} = \sigma^2 - 3\sigma + 1 = 0, \tag{2}$$

so

$$\sigma_\pm = \tfrac{1}{2}(3 \pm \sqrt{5}). \tag{3}$$

The EIGENVECTORS are found by plugging $\sigma_\pm$ into the MATRIX EQUATION

$$\begin{bmatrix} 1-\sigma_\pm & 1 \\ 1 & 2-\sigma_\pm \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}. \tag{4}$$

For σ_+, the solution is

$$y = \tfrac{1}{2}(1+\sqrt{5})x \equiv \phi x, \tag{5}$$

where ϕ is the GOLDEN RATIO, so the unstable (normalized) EIGENVECTOR is

$$\xi_+ = \tfrac{1}{10}\sqrt{50 - 10\sqrt{5}} \begin{bmatrix} 1 \\ \frac{1}{2}(1+\sqrt{5}) \end{bmatrix}. \tag{6}$$

Similarly, for σ_-, the solution is

$$y = -\tfrac{1}{2}(\sqrt{5}-1)x \equiv \phi^{-1}x, \tag{7}$$

so the stable (normalized) EIGENVECTOR is

$$\xi_- = \tfrac{1}{10}\sqrt{50 + 10\sqrt{5}} \begin{bmatrix} 1 \\ \frac{1}{2}(1-\sqrt{5}) \end{bmatrix}. \tag{8}$$

See also ANOSOV MAP

Aronhold Process

The process used to generate an expression for a covariant in the first degree of any one of the equivalent sets of COEFFICIENTS for a curve.

Arrangement

In general, an arrangement of objects is simply a grouping of them. The number of "arrangements" of n items is given either by a COMBINATION (order is ignored) or PERMUTATION (order is significant).

The division of SPACE into cells by a collection of HYPERPLANES (Agarwal and Sharir 2000) is also called an arrangement.

See also COMBINATION, CONFIGURATION, CUTTING, HYPERPLANE, ORDERING, PERMUTATION

References

Agarwal, P. K. and Sharir, M. "Arrangements and Their Applications." Ch. 2 in *Handbook of Computational Geometry* (Ed. J.-R. Sack and J. Urrutia). Amsterdam, Netherlands: North-Holland, pp. 49–19, 2000.

Arrangement Number

PERMUTATION

Array

An array is a "list of lists" with the length of each level of list the same. The size (sometimes called the "shape") of a d-dimensional array is then indicated as $\underbrace{m \times n \times x \cdots \times p}_{d}$. The most common type of array encountered is the 2-D $m \times n$ rectangular array having m columns and n rows. If $m = n$, a square array results. Sometimes, the order of the elements in an array is significant (as in a MATRIX), whereas at other times, arrays which are equivalent modulo reflections (and rotations, in the case of a square array) are considered identical (as in a MAGIC SQUARE or PRIME ARRAY).

In order to exhaustively list the number of distinct arrays of a given shape with each element being one of k possible choices, the naive algorithm of running through each case and checking to see whether it's equivalent to an earlier one is already just about as efficient as can be. The running time must be at least the number of answers, and this is so close to $k^{mn \cdots p}$ that the difference isn't significant.

However, finding the *number* of possible arrays of a given shape is much easier, and an exact formula can be obtained using the POLYA ENUMERATION THEOREM. For the simple case of an $m \times n$ array, even this proves unnecessary since there are only a few possible symmetry types, allowing the possibilities to be counted explicitly. For example, consider the case of m and n EVEN and distinct, so only reflections need be included. To take a specific case, let $m = 6$ and $n = 4$ so the array looks like

$$\begin{array}{ccc|ccc} a & b & c & d & e & f \\ g & h & i & j & k & l \\ \hline \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ m & n & o & p & q & r \\ s & t & u & v & w & x \end{array}$$

where each a, b, ..., x can take a value from 1 to k. The total number of possible arrangements is k^{24} (k^{mn} in general). The number of arrangements which are equivalent to their left-right mirror images is k^{12} (in general, $k^{mn/2}$), as is the number equal to their up-down mirror images, or their rotations through 180°. There are also k^6 arrangements (in general, $k^{mn/4}$) with full symmetry.

In general, it is therefore true that

$$\begin{cases} k^{mn/4} & \text{with full symmetry} \\ k^{mn/2} - k^{mn/4} & \text{with } only \text{ left-right reflection} \\ k^{mn/2} - k^{mn/4} & \text{with } only \text{ up-down reflection} \\ k^{mn/2} - k^{mn/4} & \text{with } only\ 180^\circ \text{ rotation,} \end{cases}$$

so there are

$$k^{mn} - 3k^{mn/2} + 2k^{mn/4}$$

arrangements with no symmetry. Now dividing by the number of images of each type, the result, for $m \neq n$ with m, n EVEN, is

$$\begin{aligned} N(m,\ n,\ k) &= \tfrac{1}{4}k^{mn} + (\tfrac{1}{2})(3)(k^{mn/2} - k^{mn/4}) \\ &\quad + \tfrac{1}{4}(k^{mn} - 3k^{mn/2} + 2k^{mn/4}) \\ &= \tfrac{1}{4}k^{mn} + \tfrac{3}{4}k^{mn/2} + \tfrac{1}{2}k^{mn/4}. \end{aligned}$$

The number is therefore of order $\mathcal{O}(k^{mn}/4)$, with "correction" terms of much smaller order.

Arrow Notation

A NOTATION invented by Knuth (1976) to represent LARGE NUMBERS in which evaluation proceeds from the right (Conway and Guy 1996, p. 60).

$m \uparrow n$	$m \cdot m \cdots m$
$m \uparrow\uparrow n$	$m \uparrow m \uparrow \cdots \uparrow m$
$m \uparrow\uparrow\uparrow n$	$\underbrace{m \uparrow\uparrow m \uparrow\uparrow \cdots \uparrow\uparrow m}_{n}$

For example,

$$m \uparrow n = m^n \tag{1}$$

$$m \uparrow\uparrow n = \underbrace{m \uparrow \cdots \uparrow m}_{n} = \underbrace{m^{m^{\cdot^{\cdot^{m}}}}}_{n}$$

$$m \uparrow\uparrow 2 = \underbrace{m \uparrow m}_{2} = m \uparrow m = m^m \tag{2}$$

$$m \uparrow\uparrow 3 = \underbrace{m \uparrow m \uparrow m}_{3} = m \uparrow (m \uparrow m)$$

$$= m \uparrow m^m = m^{m^m} \tag{3}$$

$$m \uparrow\uparrow\uparrow 2 = \underbrace{m \uparrow\uparrow\uparrow m}_{2} = m \uparrow\uparrow m = \underbrace{m^{m^{\cdot^{\cdot^{m}}}}}_{m} \tag{4}$$

$$m \uparrow\uparrow\uparrow 3 = \underbrace{m \uparrow\uparrow\uparrow m m \uparrow\uparrow\uparrow m}_{3} = m \uparrow\uparrow m = \underbrace{m^{m^{\cdot^{\cdot^{m}}}}}_{m}$$

$$= \underbrace{m\uparrow\cdots\uparrow m}_{\underbrace{m^{m^{\cdot^{\cdot^{m}}}}}_{m}} = \underbrace{m^{m^{\cdot^{\cdot^{m}}}}}_{\underbrace{m^{m^{\cdot^{\cdot^{m}}}}}_{m}} \tag{5}$$

$m\uparrow\uparrow m$ is sometimes called a POWER TOWER. The values $\underbrace{n\uparrow\cdots\uparrow n}$ are called ACKERMANN NUMBERS.

Art Gallery Theorem

Also called Chvátal's art gallery theorem. If the walls of an art gallery are made up of n straight LINE SEGMENTS, then the entire gallery can always be supervised by $\lfloor n/3 \rfloor$ watchmen placed in corners, where $\lfloor x \rfloor$ is the FLOOR FUNCTION. This theorem was proved by Chvátal (1975). It was conjectured that an art gallery with n walls and h HOLES requires $\lfloor (n+h)/3 \rfloor$ watchmen, which has now been proven by Bjorling-Sachs and Souvaine (1991, 1995) and Hoffman *et al.* (1991).

Articulation Vertex

An articulation of a CONNECTED GRAPH is a node whose removal will disconnect the graph (Chartrand 1985). In general, an articulation vertex is node of a GRAPH whose removal increases the number of components (Harary 1994, p. 26). Articulation vertices are also called cut-vertices or "cutpoints" (Harary 1994, p. 26).

A GRAPH with no articulation vertices is called a BICONNECTED GRAPH.

Artin Braid Group

BRAID GROUP

Artin L-Function

An Artin L-function over the RATIONALS $\mathbb{Q}$ encodes in a GENERATING FUNCTION information about how an irreducible MONIC POLYNOMIAL over $\mathbb{Z}$ factors when reduced modulo each PRIME. For the POLYNOMIAL x^2+1, the Artin L-function is

$$L(s,\ \mathbb{Q}(i)/\mathbb{Q},\ \mathrm{sgn}) = \prod_{p \text{ odd prime}} \frac{1}{1-\left(\frac{-1}{p}\right)p^{-s}},$$

where $(-1/p)$ is a LEGENDRE SYMBOL, which is equivalent to the EULER L-FUNCTION. The definition over arbitrary POLYNOMIALS generalizes the above expression.

Artin Reciprocity

ARTIN'S RECIPROCITY THEOREM

Artin's Conjecture

There are at least two statements which go by the name of Artin's conjecture. The first is the RIEMANN HYPOTHESIS.

The second states that every INTEGER not equal to -1 or a SQUARE NUMBER is a primitive root modulo p for infinitely many p and proposes a density for the set of such p which are always rational multiples of a constant known as ARTIN'S CONSTANT. There is an analogous theorem for functions instead of numbers which has been proved by Billharz (Shanks 1993, p. 147).

See also ARTIN'S CONSTANT, RIEMANN HYPOTHESIS

References

Artin's Constant

If $n \neq -1$ and n is not a PERFECT SQUARE, then Artin conjectured that the SET $S(n)$ of all PRIMES for which n is a PRIMITIVE ROOT is infinite. Under the assumption of the EXTENDED RIEMANN HYPOTHESIS, Artin's conjecture was solved by Hooley (1967).

If, in addition, n is not an rth POWER for any $r>1$ then let n' be the SQUAREFREE PART of n and suppose that $n' \not\equiv 1 \pmod 4$. Then Artin conjectured that the density of $S(n)$ relative to the PRIMES is given by C_{Artin}, where

$$C_{\mathrm{Artin}} = \prod_{k=1}^{\infty}\left[1-\frac{1}{p_k(p_k-1)}\right] = 0.3739558136\ldots, \tag{1}$$

and p_k is the kth PRIME, independently of the choice of n.

C_{Artin} is connected with the PRIME ZETA FUNCTION $P(n)$ by

$$\ln C_{\mathrm{Artin}} = -\sum_{n=2}^{\infty}\frac{(u_n-1)P(n)}{n}, \tag{2}$$

where

$$u_n = u_{n-1} + u_{n-2} \tag{3}$$

with $u_1=1$, $u_2=3$ (Ribenboim 1998, Gourdon and Sebah). Wrench (1961) gave 45 digits of C_{Artin}, and Gourdon and Sebah give 60.

If $n' \equiv 1 \pmod 4$ and n is still restricted not to be an rth power, then the density is not C_{Artin} itself, but a rational multiple thereof. The explicit formula for computing the density in this case is conjectured to be

$$C'_{\mathrm{Artin}} = \left[1-\mu(n')\prod_{\substack{\text{prime } q \\ q\,|\,n'}}\frac{1}{q^2-q-1}\right]C_{\mathrm{Artin}} \tag{4}$$

(Finch, Matthews 1976), where $\mu(n)$ is the MÖBIUS

FUNCTION. Special cases can be written down explicitly for $n' = p$ a PRIME,

$$C'_{\text{Artin}} = \left(1 + \frac{1}{p^2 - p - 1}\right) C_{\text{Artin}} \qquad (5)$$

or $n' = pq$, where p, q are both PRIMES with $u, v \equiv 1 \pmod 4$,

$$C'_{\text{Artin}} = \left(1 + \frac{1}{p^2 - p - 1} \frac{1}{q^2 - q - 1}\right) C_{\text{Artin}}, \qquad (6)$$

If n is a perfect cube (which is not a perfect square), a perfect fifth power (which is not a perfect square or perfect cube), etc., other formulas apply (Hooley 1967, Western and Miller 1968).

The significance of Artin's constant is more easily seen by describing it as the fraction of PRIMES p for which $1/p$ has a maximal DECIMAL EXPANSION, i.e., p is a FULL REPTEND PRIME, (Conway and Guy 1996).

Artin's Reciprocity Theorem

A general RECIPROCITY THEOREM for all orders which covered all other known reciprocity theorems when proved by E. Artin in 1927. If R is a NUMBER FIELD and R' a finite integral extension, then there is a SURJECTION from the group of fractional IDEALS prime to the discriminant, given by the Artin symbol. For some cycle c, the kernel of this SURJECTION contains each PRINCIPAL fractional IDEAL generated by an element congruent to 1 mod c.

See also LANGLANDS PROGRAM

Artinian Group

A GROUP in which any decreasing CHAIN of distinct SUBGROUPS terminates after a FINITE number.

Artinian Ring

A noncommutative SEMISIMPLE RING satisfying the "descending chain condition."

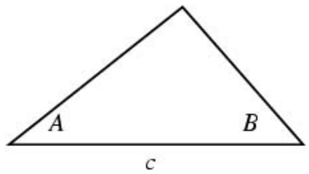
Artistic Sequence

A SERIES is called artistic if every three consecutive terms have a common three-way ratio

$$P[a_i, a_{i+1}, a_{i+2}] = \frac{(a_i + a_{i+1} + a_{i+2})a_{i+1}}{a_i a_{i+2}}.$$

A SERIES is also artistic IFF its BIAS is a constant. A GEOMETRIC SERIES with RATIO $r > 0$ is an artistic series with



$$P = \tfrac{1}{r} + 1 + r \geq 3.$$

See also BIAS (SERIES), GEOMETRIC SERIES, MELODIC SEQUENCE

ASA Theorem

Specifying two adjacent angles A and B and the side between them c uniquely determines a triangle with area

$$K = \frac{c^2}{2(\cot A + \cot B)} \tag{1}$$

The angle C is given in terms of A and B by

$$C = \pi - A - B, \tag{2}$$

and the sides a and b can be determined by using the law of sines

$$\frac{a}{\sin A} = \frac{b}{\sin B} = \frac{c}{\sin C} \tag{3}$$

to obtain

$$a = \frac{\sin A}{\sin(\pi - A - B)}\, c \tag{4}$$

$$b = \frac{\sin B}{\sin(\pi - A - B)}\, c. \tag{5}$$

See also AAA Theorem, AAS Theorem, ASS Theorem, SAS Theorem, SSS Theorem, Triangle

Aschbacher's Component Theorem

Suppose that $E(G)$ (the commuting product of all components of G) is simple and G contains a semisimple involution. Then there is some semisimple involution x such that $C_G(x)$ has a normal subgroup K which is either quasisimple or isomorphic to $O+(4, q)'$ and such that $Q = C_G(K)$ is tightly embedded.

See also Involution (Group), Isomorphic Groups, Normal Subgroup, Quasisimple Group, Simple Group, Tightly Embedded

A-Sequence

N.B. A detailed online essay by S. Finch was the starting point for this entry.

An infinite sequence of positive integers a^iS satisfying

$$1 \leq a_1 < a_2 < a_3 < \ldots \tag{1}$$

is an A-sequence if no a_k is the sum of two or more distinct earlier terms (Guy 1994). Such sequences are sometimes also known as sum-free sets.

Erdos (1962) proved

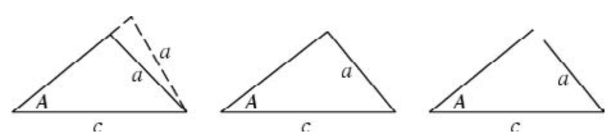
$$S(A) \equiv \sup_{\text{all A sequences}} \sum_{k=1}^{\infty} \frac{1}{a_k} < 103. \tag{2}$$

Any A-sequence satisfies the chi inequality (Levine and O'Sullivan 1977), which gives $S(A) < 3.9998$. Abbott (1987) and Zhang (1992) have given a bound from below, so the best result to date is

$$2.0649 < S(A) < 3.9998. \tag{3}$$

Levine and O'Sullivan (1977) conjectured that the sum of reciprocals of an A-sequence satisfies

$$S(A) \leq \sum_{k=1}^{\infty} \frac{1}{\chi_k} = 3.01\ldots, \tag{4}$$



where χ_i are given by the Levine-O'Sullivan greedy algorithm.

ASS Theorem

Specifying two adjacent side lengths a and c of a triangle (with $a < c$) and one acute angle A opposite a does not, in general, uniquely determine a triangle. If $\sin A < a/c$, there are two possible triangles satisfying the given conditions. If $\sin A = a/c$, there is one possible triangle. If $\sin A > a/c$, there are no possible triangles. Remember: don't try to prove congruence with the ASS theorem or you will make an ASS out of yourself.

See also AAA Theorem, AAS Theorem, SAS Theorem, SSS Theorem, Triangle

Associate

Let p be an odd prime, a a positive number such that $p|a$ (i.e., p does not divide a), and let x be one of the numbers 1, 2, 3, ..., $p-1$. Then there is a unique x',

called the associate of x, such that

$$xx' \equiv a \pmod{p}$$

with $0 < x' < p$ (Hardy and Wright 1979, p. 67). If $x' = x$, then a is called a QUADRATIC RESIDUE of p.

See also QUADRATIC RESIDUE

References

Hardy, G. H. and Wright, E. M. *An Introduction to the Theory of Numbers, 5th ed.* Oxford, England: Clarendon Press, p. 67, 1979.

Associated Fiber Bundle

Given a GROUP ACTION $G \times F \to F$ and a PRINCIPAL BUNDLE $\pi : A \to M$, the associated fiber bundle on M is

$$\tilde{\pi} : A \times F/G \to M. \quad (1)$$

In particular, it is the QUOTIENT SPACE $A \times F/G$ where $(a, x) \sim (ga, g^{-1}x)$..

For example, the torus $\mathbb{T} = \{(e^{is}, e^{it})$ has a $\mathbb{S}^1$ action given by

$$\phi(e^{i\theta})(e^{is}, e^{it}) = (e^{i(s+\theta)}, e^{i(t+\theta)}) \quad (2)$$

and the frame bundle on the sphere,

$$\pi : SO(3) \to \mathbb{S}^2, \quad (3)$$

is a principal $\mathbb{S}^1$ bundle. The associated fiber bundle is a fiber bundle on the sphere, with fiber the torus. It is an example of a four-dimensional MANIFOLD.

See also BUNDLE, FIBER BUNDLE, GROUP ACTION, PRINCIPAL BUNDLE, QUOTIENT SPACE

Associated Laguerre Polynomial

LAGUERRE POLYNOMIAL

References

Lachlan, R. *An Elementary Treatise on Modern Pure Geometry.* London: Macmillian, pp. 251–52, 1893.

Associated Vector Bundle

Given a PRINCIPAL BUNDLE $\pi : A \to M$, with fiber a LIE GROUP G and BASE MANIFOLD M, and a REPRESENTATION of G, say $\phi : G \times V \to V$, then the associated vector bundle is

$$\tilde{\pi} : A \times V/G \to M. \quad (1)$$

In particular, it is the QUOTIENT SPACE $A \times V/G$ where $(a, v) \sim (ga, g^{-1}v)$.

This construction has many uses. For instance, any REPRESENTATION of the ORTHOGONAL GROUP gives rise to a BUNDLE of TENSORS on a RIEMANNIAN MANIFOLD as the vector bundle associated to the FRAME BUNDLE.

For example, $\pi : SO(3) \to \mathbb{S}^2$ is the frame bundle on $\mathbb{S}^{2,}$ where

$$\pi\left(\begin{bmatrix} w_1 \\ w_2 \\ w_3 \end{bmatrix}\right) = w_1, \quad (2)$$

writing the special orthogonal matrix with rows w_i. It is a $SO(2)$ bundle with the action defined by

$$\begin{bmatrix}\cos\theta & -\sin\theta\\ \sin\theta & \cos\theta\end{bmatrix}\cdot A=\begin{bmatrix}1 & 0 & 0\\ 0 & \cos\theta & -\sin\theta\\ 0 & \sin\theta & \cos\theta\end{bmatrix}A, \quad (3)$$

which preserves the map π.

The TANGENT BUNDLE is the associated vector bundle with the standard REPRESENTATION of $SO(2)$ on $V=\mathbb{R}^{2,}$ given by pairs (v, A), with $v=(a, b)\in\mathbb{R}^2$ and $A\in SO(3)$. Two pairs (v_1, A_1) and (v_2, A_2) represent the same tangent vector IFF there is a $g\in SO(2)$ such that $v_2=gv_1$ and $A_1=g\cdot A_2$.

See also ASSOCIATED FIBER BUNDLE, FRAME BUNDLE, GROUP ACTION, LIE GROUP, PRINCIPAL BUNDLE, REPRESENTATION, QUOTIENT SPACE

Associative

Three elements x, y and z of a set S are said to be associative under a binary operation * if they satisfy

$$x*(y*z)=(x*y)*z.$$

Real numbers are associative under addition

$$x+(y+z)=(x+y)+z$$

and multiplication

$$x\cdot(y\cdot z)=(x\cdot y)\cdot z.$$

See also ASSOCIATIVE ALGEBRA, COMMUTATIVE, DISTRIBUTIVE, TRANSITIVE

Associative Algebra

In simple terms, let x, y, and z be members of an ALGEBRA. Then the ALGEBRA is said to be associative if

$$x\cdot(y\cdot z)=(x\cdot y)\cdot z, \quad (1)$$

where $\cdot$ denotes MULTIPLICATION. More formally, let A denote an $\mathbb{R}$-algebra, so that A is a VECTOR SPACE over $\mathbb{R}$ and

$$A\times A\to A \quad (2)$$

$$(x, y)\to x\cdot y. \quad (3)$$

Then A is said to be m-associative if there exists an m-dimensional SUBSPACE S of A such that

$$(y\cdot x)\cdot z=y\cdot(x\cdot z) \quad (4)$$

for all $y, z\in A$ and $x\in S$. Here, VECTOR MULTIPLICATION $x\cdot y$ is assumed to be BILINEAR. An n-dimensional n-associative ALGEBRA is simply said to be "associative."

An $n\times n$ MAGIC SQUARE for which every pair of numbers symmetrically opposite the center sum to n^2+1. The LO SHU is associative but not PANMAGIC. Order four squares can be PANMAGIC or associative, but not both. Order five squares are the smallest which can be both associative and PANMAGIC, and 16 distinct associative PANMAGIC SQUARES exist, one of which is illustrated above (Gardner 1988).

See also MAGIC SQUARE, PANMAGIC SQUARE

Associator

For an ALGEBRA A, the associator is the trilinear map $A\times A\times A\to A$ given by

$$(x, y, z)=(xy)z-x(yz).$$

The associator is identically zero IFF A is associative.

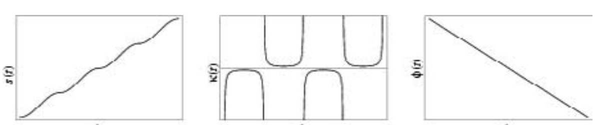
Asterisk

STAR

Astroid

A 4-cusped HYPOCYCLOID which is sometimes also called a TETRACUSPID, CUBOCYCLOID, or PARACYCLE. The PARAMETRIC EQUATIONS of the astroid can be obtained by plugging in $n \equiv a/b = 4$ or $4/3$ into the equations for a general HYPOCYCLOID, giving

$$x = 3b \cos\phi + b\cos(3\phi) = 4b\cos^3\phi = a\cos^3\phi \quad (1)$$



$$y = 3b \sin\phi - b\sin(3\phi) = 4b\sin^3\phi = a\sin^3\phi. \quad (2)$$

In CARTESIAN COORDINATES,

$$x^{2/3} + y^{2/3} = a^{2/3}. \quad (3)$$

In PEDAL COORDINATES with the PEDAL POINT at the center, the equation is

$$r^2 + 3p^2 = a^2 \quad (4)$$

The ARC LENGTH, CURVATURE, and TANGENTIAL ANGLE are

$$s(t) = \frac{3}{2}\int_0^t |\sin(2t')|\,dt' = \frac{3}{2}\sin^2 t \quad (5)$$

$$\kappa(t) = -\frac{2}{3}\csc(2t) \quad (6)$$

$$\phi(t) = -t. \quad (7)$$

As usual, care must be taken in the evaluation of $s(t)$ for $t > \pi/2$. Since (5) comes from an integral involving the ABSOLUTE VALUE of a function, it must be monotonic increasing. Each QUADRANT can be treated correctly by defining

$$n = \left\lfloor \frac{2t}{\pi} \right\rfloor + 1, \quad (8)$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION, giving the formula

$$s(t) = (-1)^{+1[n \pmod 2]}\frac{3}{2}\sin^2 t + 3\lfloor \tfrac{1}{2} n \rfloor. \quad (9)$$

The overall ARC LENGTH of the astroid can be computed from the general HYPOCYCLOID formula

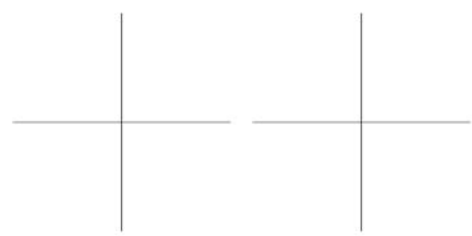
$$s_n = \frac{Sa(n-1)}{n} \quad (10)$$

with $n = 4$,

$$s_4 = 6a. \quad (11)$$

The AREA is given by

$$A_n = \frac{(n-1)(n-2)}{n^2}\pi a^2 \quad (12)$$



with $n = 4$,

$$A_4 = \frac{3}{8}\pi a^2. \quad (13)$$

The EVOLUTE of an ELLIPSE is a stretched HYPOCYCLOID. The gradient of the TANGENT T from the point with parameter p is $-\tan p$. The equation of this TANGENT T is

$$x \sin p + y \cos p = \frac{1}{2} a \sin(2p) \quad (14)$$

(MacTutor Archive). Let T cut the X-AXIS and the Y-AXIS at X and Y, respectively. Then the length XY is a constant and is equal to a.

The astroid can also be formed as the ENVELOPE produced when a LINE SEGMENT is moved with each end on one of a pair of PERPENDICULAR axes (e.g., it is the curve enveloped by a ladder sliding against a wall or a garage door with the top corner moving along a vertical track; left figure above). The astroid is therefore a GLISSETTE. To see this, note that for a ladder of length L, the points of contact with the wall and floor are $(x_0, 0)$ and $(0, \sqrt{L^2 - x_0^2})$, respectively. The equation of the LINE made by the ladder with its foot at $(x_0, 0)$ is therefore

$$y - 0 = \frac{\sqrt{L^2 - x_0^2}}{-x_0}(x - x_0) \quad (15)$$

which can be written

$$U(x, y, x_0) = y + \frac{\sqrt{L^2 - x_0^2}}{x_0}(x - x_0). \quad (16)$$

The equation of the ENVELOPE is given by the simultaneous solution of

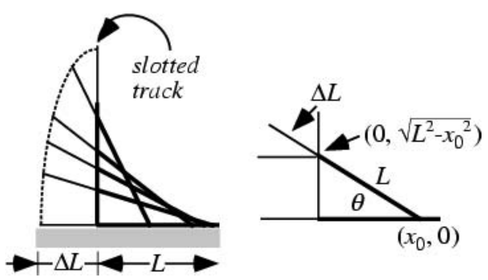
$$\begin{cases} U(x,\ y,\ x_0) = y + \dfrac{\sqrt{L^2 - x_0^2}}{x_0}(x - x_0) = 0 \\ \dfrac{\partial U}{\partial x_0} = \dfrac{x_0^2 - L^2 x}{x_0^2\sqrt{L^2 - x_0^2}} = 0, \end{cases} \tag{17}$$

which is

$$x = \frac{x_0^3}{L^2} \tag{18}$$

$$y = \frac{(L^2 - x_0^2)^{3/2}}{L^2} \tag{19}$$

Noting that



$$x^{2/3} = \frac{x_0^2}{L^{4/3}} \tag{20}$$

$$y^{2/3} = \frac{L^2 - x_0^2}{L^{4/3}} \tag{21}$$

allows this to be written implicitly as

$$x^{2/3} + y^{2/3} = L^{2/3}, \tag{22}$$

the equation of the astroid, as promised.

The related problem obtained by having the "garage door" of length L with an "extension" of length ΔL move up and down a slotted track also gives a surprising answer. In this case, the position of the "extended" end for the foot of the door at horizontal position x_0 and ANGLE θ is given by

$$x = -\Delta L \cos\theta \tag{23}$$

$$y = \sqrt{L^2 - x_0^2} + \Delta L \sin\theta. \tag{24}$$

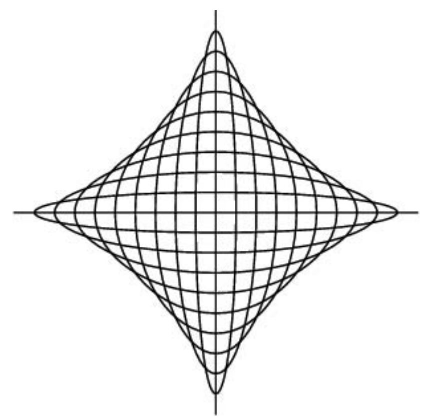
Using

$$x_0 = L\cos\theta \tag{25}$$

then gives

$$x = -\frac{\Delta L}{L}\, x_0 \tag{26}$$

$$y = \sqrt{L^2 - x_0^2}\left(1 + \frac{\Delta L}{L}\right) \tag{27}$$



Solving (26) for x_0, plugging into (27) and squaring then gives

$$y^2 = L^2 - \frac{L^2 x^2}{(\Delta L)^2}\left(1 + \frac{\Delta L}{L}\right)^2. \tag{28}$$

Rearranging produces the equation

$$\frac{x^2}{(\Delta L)^2} + \frac{y^2}{(L + \Delta L)^2} = 1, \tag{29}$$

the equation of a (QUADRANT of an) ELLIPSE with SEMIMAJOR and SEMIMINOR AXES of lengths δl and $l + \delta l$.

the astroid is also the ENVELOPE of the family of ELLIPSES

$$\frac{x^2}{c^2} + \frac{y^2}{(1 - c)^2} - 1 = 0, \tag{30}$$

illustrated above (Wells 1991).

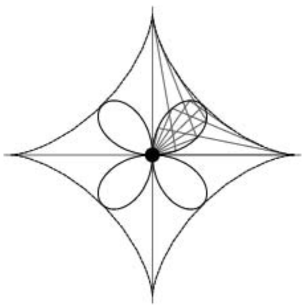
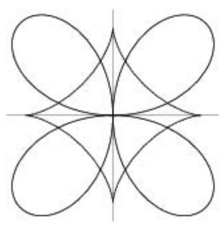
Astroid Evolute



A HYPOCYCLOID EVOLUTE for $n = 4$ is another ASTROID scaled by a factor $n/(n-2) = 4/2 = 2$ and rotated $1/(2 \cdot 4) = 1/8$ of a turn.

Astroid Involute



A HYPOCYCLOID INVOLUTE for $n = 4$ is another ASTROID scaled by a factor $(n-2)/n = 2/4 = 1/2$ and rotated $1/(2 \cdot 4) = 1/8$ of a turn.

Astroid Pedal Curve

The PEDAL CURVE of an ASTROID with PEDAL POINT at the center is a QUADRIFOLIUM.

Astroid Radial Curve

The QUADRIFOLIUM

$$x = x_0 + 3a \cos t - 3a \cos(3t)$$

$$y = y_0 + 3a \sin t + 3 \sin(3t).$$

Astroidal Ellipsoid

The surface which is the inverse of the ELLIPSOID in the sense that it "goes in" where the ELLIPSOID "goes out." It is given by the PARAMETRIC EQUATIONS

$$x = (a \cos u \cos v)^3$$

$$y = (b \sin u \cos v)^3$$

$$z = (c \sin v)^3$$

for $u \in [-\pi/2, \pi/2]$ and $v \in [-\pi, \pi]$. The special case $a = b = c = 1$ corresponds to the HYPERBOLIC OCTAHEDRON.

Asymptosy

ASYMPTOTIC behavior. A useful yet endangered word, found rarely outside the captivity of the *Oxford English Dictionary*.

See also ASYMPTOTE, ASYMPTOTIC

Asymptote

A curve approaching a given curve arbitrarily closely, as illustrated in the above diagram.

See also ASYMPTOSY, ASYMPTOTIC, ASYMPTOTIC CURVE

References

Giblin, P. J. "What is an Asymptote?" *Math. Gaz.* **56**, 274–84, 1972.

Asymptotic

Approaching a value or curve arbitrarily closely (i.e., as some sort of LIMIT is taken). A CURVE A which is asymptotic to given CURVE C is called the ASYMPTOTE

of C. Hardy and Wright (1979, p. 7) use the symbol $\asymp$ to denote that one quantity is asymptotic to another. If $f \asymp \phi$, then Hardy and Wright say that f and ϕ are of the same ORDER OF MAGNITUDE.

See also ASYMPTOSY, ASYMPTOTE, ASYMPTOTIC CURVE, ASYMPTOTIC DIRECTION, ASYMPTOTIC NOTATION, ASYMPTOTIC SERIES, LANDAU SYMBOL, LIMIT, ORDER OF MAGNITUDE

References

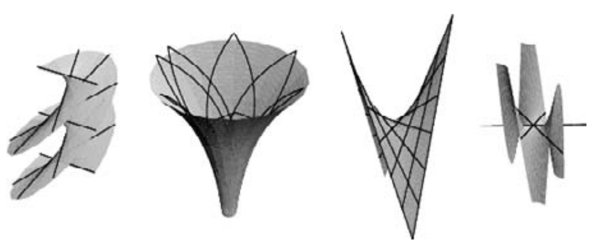
Asymptotic Curve

Given a REGULAR SURFACE M, an asymptotic curve is formally defined as a curve $\mathbf{x}(t)$ on M such that the NORMAL CURVATURE is 0 in the direction $\mathbf{x}'(t)$ for all t in the domain of $\mathbf{x}$. The differential equation for the parametric representation of an asymptotic curve is

$$eu'^2 + 2fu'v' + gv'^2 = 0, \quad (1)$$



where e, f, and g are coefficients of the SECOND FUNDAMENTAL FORM. The differential equation for asymptotic curves on a MONGE PATCH $(u, v, h(u, v))$ is

$$h_{uu}u'^2 + 2h_{uu}u'v' + h_{vv}v'^2 = 0, \quad (2)$$

and on a polar patch $(r \cos\theta, r \sin\theta, h(r))$ is

$$h''(r)r'^2 + h'(r)r\theta'^2 = 0. \quad (3)$$

The images below show asymptotic curves for the ELLIPTIC HELICOID, FUNNEL, HYPERBOLIC PARABOLOID, and MONKEY SADDLE.

Asymptotic Equipartition Property

This entry contributed by ERIK G. MILLER

A theorem from INFORMATION THEORY that is a simple consequence of the WEAK LAW OF LARGE NUMBERS. It states that if a set of values X_1, X_2, ..., X_n is drawn independently from a random variable X distributed according to $P(x)$ then the joint probability $P(X_1, \ldots, X_n)$ satisfies

$$-\frac{1}{n} \ln P(X_1, X_2, \ldots, X_n) \to H(X),$$

where $H(X)$ is the ENTROPY of the random variable X.

See also ENTROPY

Asymptotic Expansion

ASYMPTOTIC SERIES

Asymptotic Notation

Let n be a integer variable which tends to infinity and let x be a continuous variable tending to some limit. Also, let $\phi(n)$ or $\phi(x)$ be a positive function and $f(n)$ or $f(x)$ any function. Then Hardy and Wright (1979) define

1. $f = \mathcal{O}(\phi)$ to mean that $|f| < A\phi$ for some constant A and all values of n and x,
2. $f = o(\phi)$ to mean that $f/\phi \to 0$,
3. $f \sim \phi$ to mean that $f/\phi \to 1$,
4. $f \prec \phi$ to mean the same as $f = o(\phi)$,
5. $f \prec \phi$ to mean $f/\phi \to \infty$, and
6. $f \asymp \phi$ to mean $A_1\phi < f < A_2\phi$ for some positive constants A_1 and A_2.

$f = o(\phi)$ implies and is stronger than $f = \mathcal{O}(\phi)$.

The term LANDAU SYMBOL is sometimes used to indicate the notation $o(\phi)$, and in general, $\mathcal{O}(x)$ and $o(x)$ are read as "is of order x."

See also LANDAU SYMBOL

Asymptotic Series

An asymptotic series is a SERIES EXPANSION of a FUNCTION in a variable x which may converge or diverge (Erdélyi 1987, p. 1), but whose partial sums can be made an arbitrarily good approximation to a given function for large enough x. To form an asymptotic series $R(x)$ of

$$f(x) \sim R(x), \tag{1}$$

take

$$x^n R_n(x) = x^n [f(x) - S_n(x)], \tag{2}$$

where

$$S_n(x) \equiv a_0 + \frac{a_1}{x} + \frac{a_2}{x^2} + \cdots + \frac{a_n}{x^n}. \tag{3}$$

The asymptotic series is defined to have the properties

$$\lim_{x\to\infty} x^n R_n(x) = 0 \quad \text{for fixed } n \tag{4}$$

$$\lim_{x\to\infty} x^n R_n(x) = \infty \quad \text{for fixed } x \tag{5}$$

Therefore,

$$f(x) \approx \sum_{n=0}^{\infty} a_n x^{-n} \tag{6}$$

in the limit $x \to \infty$. If a function has an asymptotic expansion, the expansion is unique. The symbol $\sim$ is also used to mean directly SIMILAR.

Atkin-Goldwasser-Kilian-Morain Certificate

A recursive PRIMALITY CERTIFICATE for a PRIME p. The certificate consists of a list of

1. A point on an ELLIPTIC CURVE C

$$y^2 = x^3 + g_2 x + g_3 \pmod p$$

for some numbers g_2 and g_3.

2. A PRIME q with $q > (p^{1/4}+1)^2$, such that for some other number k and $m = kq$ with $k \neq 1$, $mC(x, y, g_2, g_3, p)$ is the identity on the curve, but $kC(x, y, g_2, g_3, p)$ is not the identity. This guarantees PRIMALITY of p by a theorem of Goldwasser and Kilian (1986).

3. Each q has its recursive certificate following it. So if the smallest q is known to be PRIME, all the numbers are certified PRIME up the chain.

A PRATT CERTIFICATE is quicker to generate for small numbers. The *Mathematica* task `ProvablePrimeQ[n]` in the *Mathematica* add-on package ``NumberTheory`PrimeQ` `` (which can be loaded with the command ``<<NumberTheory` ``) therefore generates an Atkin-Goldwasser-Kilian-Morain certificate only for numbers above a certain limit (10^{10} by default), and a PRATT CERTIFICATE for smaller numbers.

See also ELLIPTIC CURVE PRIMALITY PROVING, ELLIPTIC PSEUDOPRIME, PRATT CERTIFICATE, PRIMALITY CERTIFICATE, WITNESS

Atlas

An atlas is a collection of consistent COORDINATE CHARTS on a MANIFOLD, where "consistent" most commonly means that the TRANSITION FUNCTIONS of the charts are SMOOTH. As the name suggests, an atlas corresponds to a collection of maps, each of which shows a piece of a MANIFOLD and looks like flat two-dimensional Euclidean space. To use an atlas, one needs to know how the maps overlap. To be useful, the maps must not be too different on these overlapping areas.

The overlapping maps from one chart to another are called transition functions. They represent the transition from one chart's point of view to that of another. Let the open unit ball in $\mathbb{R}^n$ be denoted B_1. Then if $\phi : U \to B_1$ and $\psi : V \to B_1$ are two coordinate charts, the composition $\phi \circ \psi^{-1}$ is a function defined on $\psi(U \cap V)$. That is, it is a function from an open subset of B_1 to B_1, and given such a function from $\mathbb{R}^n$ to $\mathbb{R}^n$, there are conditions for it to be smooth or have k smooth derivatives (i.e., it is a C-K FUNCTION). Furthermore, when $\mathbb{R}^{2n}$ is isomorphic to $\mathbb{C}^n$ (in the even DIMENSIONAL case), a function can be HOLOMORPHIC.

A smooth atlas has transition functions that are C-INFINITY smooth (i.e., infinitely differentiable). The consequence is that a smooth function on one chart is smooth in any other chart (by the CHAIN RULE for higher derivatives). Similarly, one could have an atlas in class C^k where the transition functions are in class C-K.

In the even-dimensional case, one may ask whether the transition functions are HOLOMORPHIC. In this case, one has a holomorphic atlas, and by the chain rule, it makes sense to ask if a function on the manifold is holomorphic.

It is possible for two atlases to be compatible, meaning the union is also an atlas. By ZORN'S LEMMA, there always exists a maximal atlas, where a maximal atlas is an atlas not contained in any other atlas. However, in typical applications, it is not necessary to use a maximal atlas and any sufficiently refined atlas will do.

See also COORDINATE CHART, HOLOMORPHIC FUNCTION, MANIFOLD, SMOOTH FUNCTION, TRANSITION FUNCTION, ZORN'S LEMMA

Atom

ATOMIC STATEMENT, URELEMENT

Atomic Statement

In LOGIC, a statement which cannot be broken down into smaller statements.

Attraction Basin

BASIN OF ATTRACTION

Attractor

An attractor is a SET of states (points in the PHASE SPACE), invariant under the dynamics, towards which neighboring states in a given BASIN OF ATTRACTION asymptotically approach in the course of dynamic evolution. An attractor is defined as the smallest unit which cannot be itself decomposed into two or more attractors with distinct BASINS OF ATTRACTION. This restriction is necessary since a DYNAMICAL SYSTEM may have multiple attractors, each with its own BASIN OF ATTRACTION.

Conservative systems do not have attractors, since the motion is periodic. For dissipative DYNAMICAL SYSTEMS, however, volumes shrink exponentially so attractors have 0 volume in n-D phase space.

A stable FIXED POINT surrounded by a dissipative region is an attractor known as a SINK. Regular attractors (corresponding to 0 LYAPUNOV CHARACTERISTIC EXPONENTS) act as LIMIT CYCLES, in which trajectories circle around a limiting trajectory which they asymptotically approach, but never reach. STRANGE ATTRACTORS are bounded regions of PHASE SPACE (corresponding to POSITIVE LYAPUNOV CHARACTERISTIC EXPONENTS) having zero MEASURE in the embedding PHASE SPACE and a FRACTAL DIMENSION. Trajectories within a STRANGE ATTRACTOR appear to skip around randomly.

See also BARNSLEY'S FERN, BASIN OF ATTRACTION, CHAOS GAME, FRACTAL DIMENSION, LIMIT CYCLE, LYAPUNOV CHARACTERISTIC EXPONENT, MEASURE, SINK (MAP), STRANGE ATTRACTOR

Aubel's Theorem

VON AUBEL'S THEOREM

Auction

A type of sale in which members of a group of buyers offer ever increasing amounts. The bidder making the

last bid (for which no higher bid is subsequently made within a specified time limit: "going once, going twice, sold") must then purchase the item in question at this price. Variants of simple bidding are also possible, as in a VICKREY AUCTION.

See also VICKREY AUCTION

Augend

The first of several ADDENDS, or "the one to which the others are added," is sometimes called the augend. Therefore, while a, b, and c are ADDENDS in $a + b + c$, a is the augend.

See also ADDEND, ADDITION

Augmented Amicable Pair

A PAIR of numbers m and n such that

$$\sigma(m) = \sigma(n) = m + n - 1,$$

where $\sigma(m)$ is the DIVISOR FUNCTION. Beck and Najar (1977) found 11 augmented amicable pairs.

Aureum Theorema

Gauss's name for the QUADRATIC RECIPROCITY THEOREM.

Aurifeuillean Factorization

A factorization OF THE FORM

$$2^{4n+2}+1=(2^{2n+1}-2^{n+1}+1)(2^{2n+1}+2^{n+1}+1). \quad (1)$$

The factorization for $n=14$ was discovered by Aurifeuille, and the general form was subsequently discovered by Lucas. The large factors are sometimes written as L and M as follows

$$2^{4k-2}+1=(2^{2k-1}-2^k+1)(2^{2k-1}+2^k+1) \quad (2)$$

$$3^{6k-3}+1=(3^{2k-1}+1)(3^{2k-1}-3^k+1) \times(3^{2k-1}+3^k+1), \quad (3)$$

which can be written

$$2^{2h}+1=L_{2h}M_{2h} \quad (4)$$

$$3^{3h}+1=(3^h+1)L_{3h}M_{3h} \quad (5)$$

$$5^{5k}-1=(5^h+1)L_{5h}M_{5h}, \quad (6)$$

where $h=2k-1$ and

$$L_{2h},\ M_{2h}=2^h+1\mp 2^k \quad (7)$$

$$L_{3h},\ M_{3h}=3^h+1\mp 3^k \quad (8)$$

$$L_{5h},\ M_{5h}=5^{2h}+3\cdot 5^h+1\mp 5^k(5^k+1). \quad (9)$$

Ausdehnungslehre

EXTERIOR ALGEBRA

Aut

"Aut" is the term applied in PROPOSITIONAL CALCULUS to the XOR connective. "Aut" is Latin form for "either/or (but not both)," e.g., "Aut Caesar aut nihil" (Cesare Borgia; 1476–507).

The symbol Aut is also commonly used for the completely different purpose of denoting an AUTOMORPHISM.

See also AUTOMORPHISM, XOR

Authalic Latitude

An AUXILIARY LATITUDE which gives a SPHERE equal SURFACE AREA relative to an ELLIPSOID. The authalic latitude is defined by

$$\beta=\sin^{-1}\left(\frac{q}{q_p}\right), \quad (1)$$

where

$$q=(1-e^2)\left[\frac{\sin\phi}{1-e^2\sin^2\phi}-\frac{1}{2e}\ln\left(\frac{1-e\sin\phi}{1+e\sin\phi}\right)\right] \quad (2)$$

and q_p is q evaluated at the north pole ($\phi=90°$). Let R_q be the RADIUS of the SPHERE having the same SURFACE AREA as the ELLIPSOID, then

$$R_q=a\sqrt{\frac{q_p}{2}}. \quad (3)$$

The series for β is

$$\beta=\phi-(\tfrac{1}{3}e^2+\tfrac{31}{180}e^4+\tfrac{59}{560}e^6+\ldots)\sin(\phi) +(\tfrac{17}{360}e^4+\tfrac{61}{1260}e^6+\ldots)\sin(4\phi) -(\tfrac{383}{45360}e^6+\ldots)\sin(6\phi)+\ldots. \quad (4)$$

The inverse FORMULA is found from

$$\Delta\phi = \frac{(1-e^2\sin^2\phi)^2}{2\cos\phi} \times \left[\frac{q}{1-e^2} - \frac{\sin\phi}{1-e^2\sin^2\phi} + \frac{1}{2e}\ln\left(\frac{1-e\sin\phi}{1+e\sin\phi}\right)\right], \quad (5)$$

where

$$q = q_p \sin\beta \quad (6)$$

and $\phi_0 = \sin^{-1}(q/2)$. This can be written in series form as

$$\phi = \beta + (\tfrac{1}{3}e^2 + \tfrac{31}{180}e^4 + \tfrac{517}{5040}e^6 + \ldots)\sin(2\beta).$$
$$+(\tfrac{23}{360}e^4 + \tfrac{251}{3780}e^6 + \ldots)\sin(4\beta)$$
$$+(\tfrac{761}{45360}e^6 + \ldots)\sin(6\beta) + \ldots. \quad (7)$$

Autocorrelation

The autocorrelation function $R_f(t)$ of a real function $f(t)$ is defined by

$$R_f(t) \equiv \lim_{T\to\infty} \frac{1}{2T}\int_{-T}^{T} f(\tau)f(T+\tau)\,d\tau \quad (1)$$

(Papoulis 1962, p. 241). For a complex function, the autocorrelation $\rho_f(t)$ is defined by

$$\rho_f(t) \equiv f \star f = \bar{f}(-t) * f(t) = \int_{-\infty}^{\infty} f(t+\tau)\bar{f}(\tau)\,d\tau. \quad (2)$$

where $*$ denotes CONVOLUTION, $\star$ denotes CROSS-CORRELATION, and $\bar{f}$ is the COMPLEX CONJUGATE (Papoulis 1962, pp. 241–42). The autocorrelation discards phase information, returning only the power, and is therefore an irreversible operation.

There is also a somewhat surprising and extremely important relationship between the autocorrelation and the FOURIER TRANSFORM known as the WIENER-KHINTCHINE THEOREM. Let $\mathcal{F}[f(x)] = F(k)$, and $\bar{F}$ denote the COMPLEX CONJUGATE of F, then the FOURIER TRANSFORM of the ABSOLUTE SQUARE of $F(k)$ is given by

$$\mathcal{F}[|F(k)|^2] = \int_{-\infty}^{\infty} \bar{f}(\tau)f(\tau+x)\,d\tau. \quad (3)$$

The autocorrelation is a HERMITIAN OPERATOR since $\rho_f(-t) = \bar{\rho}_f(t)$.

$f \star f$ is MAXIMUM at the ORIGIN; in other words,

$$\int_{-\infty}^{\infty} f(u)f(u+x)\,du \le \int_{-\infty}^{\infty} f^2(u)\,du. \quad (4)$$

To see this, let ϵ be a REAL NUMBER. Then

$$\int_{-\infty}^{\infty} [f(u) + \epsilon f(u+x)]^2\,du > 0 \quad (5)$$

$$\int_{-\infty}^{\infty} f^2(u)\,du + 2\epsilon\int_{-\infty}^{\infty} f(u)f(u+x)\,du + e^2\int_{-\infty}^{\infty} f^2(u+x)\,du > 0 \quad (6)$$

$$\int_{-\infty}^{\infty} f^2(u)\,du + 2\epsilon\int_{-\infty}^{\infty} f(u)f(u+x)\,du + e^2\int_{-\infty}^{\infty} f^2(u+x)\,du > 0. \quad (7)$$

Define

$$a \equiv \int_{-\infty}^{\infty} f^2(u)\,du \quad (8)$$

$$b \equiv 2\int_{-\infty}^{\infty} f(u)f(u+x)\,du. \quad (9)$$

Then plugging into above, we have $a\epsilon^2 + b\epsilon + c > 0$. This QUADRATIC EQUATION does not have any REAL ROOT, so $b^2 - 4ac \le 0$, i.e., $b/2 \le a$. It follows that

$$\int_{-\infty}^{\infty} f(u)f(u+x)\,du \le \int_{-\infty}^{\infty} f^2(u)\,du, \quad (10)$$

with the equality at $x = 0$. This proves that $f \star f$ is MAXIMUM at the ORIGIN.

Automatic Set

A k-automatic set is a set of integers whose base-k representations form a regular language, i.e., a language accepted by a finite automaton or state machine. If bases a and b are incompatible (do not have a common power) and if an a-automatic set S_a and b-automatic set S_b are both of density 0 over the integers, then it is believed that $S_a \cap S_b$ is finite. However, this problem has not been settled.

Some automatic sets, such as the 2-automatic consisting of numbers whose BINARY representations contain at most two 1s: 1, 2, 3, 4, 5, 6, 8, 9, 10, 12, 16, 17, 18, ... (Sloane's A048645) have a simple arithmetic expression. However, this is not the case for general k-automatic sets.

Automorphic Function

An automorphic function $f(z)$ of a COMPLEX variable z is one which is analytic (except for POLES) in a domain D and which is invariant under a DENUMERABLY INFINITE group of LINEAR FRACTIONAL TRANSFORMATIONS (also known as MÖBIUS TRANSFORMATIONS)

$$z' = \frac{az + b}{cz + d}.$$

Automorphic functions are generalizations of TRIGONOMETRIC FUNCTIONS and ELLIPTIC FUNCTIONS.

Automorphic Number

A number k such that nk^2 has its last digits equal to k is called n-automorphic. For example, $1 \cdot \underline{5}^2 \equiv 2\underline{5}$ (Wells 1986, pp. 58–9) and $1 \cdot \underline{6}^2 \equiv 3\underline{6}$ (Wells 1986, p. 68) are 1-automorphic and $2 \cdot \underline{8}^2 \equiv 12\underline{8}$ and $2 \cdot \underline{88}^2 = 154\underline{88}$ are 2-automorphic. de Guerre and Fairbairn (1968) give a history of automorphic numbers.

The first few 1-automorphic numbers are 1, 5, 6, 25, 76, 376, 625, 9376, 90625, ... (Sloane's A003226, Wells 1986, p. 130). There are two 1-automorphic numbers with a given number of digits, one ending in 5 and one in 6 (except that the 1-digit automorphic numbers include 1), and each of these contains the previous number with a digit prepended. Using this fact, it is possible to construct automorphic numbers having more than 25,000 digits (Madachy 1979). The first few 1-automorphic numbers ending with 5 are 5, 25, 625, 0625, 90625, ... (Sloane's A007185), and the first few ending with 6 are 6, 76, 376, 9376, 09376, ... (Sloane's A016090). The 1-automorphic numbers $a(n)$ ending in 5 are IDEMPOTENT (mod 10^n) since

$$[a(n)]^2 \equiv a(n) (\text{mod } 10^n)$$

(Sloane and Plouffe 1995).

The following table gives the 10-digit n-automorphic numbers.

n	n-Automorphic Numbers	Sloane
1	0000000001, 8212890625, 1787109376	–, A007185, A016090

2	0893554688	A030984
3	6666666667, 7262369792, 9404296875	–, A030985, A030986
4	0446777344	A030987
5	3642578125	A030988
6	3631184896	A030989
7	7142857143, 4548984375, 1683872768	A030990, A030991, A030992
8	0223388672	A030993
9	5754123264, 3134765625, 8888888889	A030994, A030995, –

The infinite 1-automorphic number ending in 5 is given by ...56259918212890625 (Sloane's A018247), while the infinite 1-automorphic number ending in 6 is given by ...740081787109376 (Sloane's A018248).

Automorphism

An ISOMORPHISM of a system of objects onto itself. The term derives from the Greek prefix $\alpha\upsilon\tau o$ (*auto*) "self" and $\mu o\rho\varphi\omega\sigma\iota\varsigma$ (*morphosis*) "to form" or "to shape."

The automorphisms of a GRAPH always describe a GROUP (Skiena 1990, p. 19).

An automorphism of a region of the COMPLEX PLANE is a conformal SELF-MAP (Krantz 1999, p. 81).

See also ANOSOV AUTOMORPHISM, GRAPH AUTOMORPHISM

References

Skiena, S. *Implementing Discrete Mathematics: Combinatorics and Graph Theory with Mathematica.* Reading, MA: Addison-Wesley, 1990.

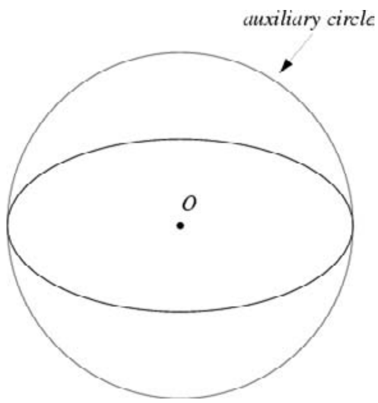
Automorphism Group

The GROUP of functions from an object G to itself which preserve the structure of the object, denoted $Aut(G)$. The automorphism group of a GROUP preserves the MULTIPLICATION table, the automorphism group of a GRAPH the INCIDENCE MATRICES, and that of a FIELD the ADDITION and MULTIPLICATION tables.

Autonomous

A differential equation or system of ORDINARY DIFFERENTIAL EQUATIONS is said to be autonomous if it does not explicitly contain the independent variable (usually denoted t). A second-order autonomous differential equation is OF THE FORM $F(y, y', y'') = 0$, where $y' \equiv dy/dt \equiv v$. By the CHAIN RULE, y'' can be expressed as

$$y'' = v' = \frac{dv}{dt} = \frac{dv}{dy}\frac{dy}{dt} = \frac{dv}{dy}\,v.$$



For an autonomous ODE, the solution is independent of the time at which the initial conditions are applied. This means that all particles pass through a given point in phase space. A nonautonomous system of n first-order ODEs can be written as an autonomous system of $n+1$ ODEs by letting $t \equiv x_{n+1}$ and increasing the dimension of the system by 1 by adding the equation

$$\frac{dx_{n+1}}{dt} = 1.$$

Autoregressive Model

MAXIMUM ENTROPY METHOD

Auxiliary Circle

The CIRCUMCIRCLE of an ELLIPSE, i.e., the CIRCLE whose CENTER concurs with that of the ELLIPSE and whose RADIUS is equal to the ELLIPSE's SEMIMAJOR AXIS.

Axiom A Diffeomorphism

Let $\phi : M \to M$ be a C^1 DIFFEOMORPHISM on a compact RIEMANNIAN MANIFOLD M. Then ϕ satisfies Axiom A if the NONWANDERING set $\Omega(\phi)$ of ϕ is hyperbolic and the PERIODIC POINTS of ϕ are DENSE in $\omega(\phi)$. although it was conjectured that the first of these conditions implies the second, they were shown to be independent in or around 1977. examples include the ANOSOV DIFFEOMORPHISMS and SMALE HORSESHOE MAP.

In some cases, Axiom A can be replaced by the condition that the DIFFEOMORPHISM is a hyperbolic diffeomorphism on a hyperbolic set (Bowen 1975, Parry and Pollicott 1990).

Axiom A Flow

A FLOW defined analogously to the AXIOM A DIFFEOMORPHISM, except that instead of splitting the TANGENT BUNDLE into two invariant sub-BUNDLES, they are split into three (one exponentially contracting, one expanding, and one which is 1-dimensional and tangential to the flow direction).

See also DYNAMICAL SYSTEM

Axiom of Choice

An important and fundamental axiom in SET THEORY sometimes called ZERMELO'S AXIOM OF CHOICE. It was formulated by Zermelo in 1904 and states that, given any SET of mutually exclusive nonempty SETS, there exists at least one SET that contains exactly one element in common with each of the nonempty SETS. The axiom of choice is related to the first of HILBERT'S PROBLEMS.

In ZERMELO-FRAENKEL SET THEORY (in the form omitting the axiom of choice), the ZORN'S LEMMA, TRICHOTOMY LAW, and the WELL ORDERING PRINCIPLE are equivalent to the axiom of choice (Mendelson 1997, p. 275). In contexts sensitive to the axiom of choice, the notation "ZF" is often used to denote Zermelo-Fraenkel *without* the axiom of choice, while "ZFC" is used if the axiom of choice is included.

In 1940, Gödel proved that the axiom of choice is CONSISTENT with the axioms of VON NEUMANN-BERNAYS-GÖDEL SET THEORY (a conservative extension of ZERMELO-FRAENKEL SET THEORY). However, in 1963, Cohen (1963) unexpectedly demonstrated that the axiom of choice is also *independent* of ZERMELO-FRAENKEL SET THEORY (Mendelson 1997; Boyer and Merzbacher 1991, pp. 610–11).

Axiom of Comprehension

AXIOM OF SEPARATION

Axiom of Extensionality

The axiom of ZERMELO-FRAENKEL SET THEORY which asserts that sets formed by the same elements are equal,

$$\forall x(x \in a \equiv x \in b) \Rightarrow a = b.$$

Using the notation $a \subset b$ (a is a SUBSET of b) for $x \in a(x \in b)$, the axiom can be rewritten

$$a \subset b \wedge b \subset a \Rightarrow a = b.$$

Axiom of Foundation

One of the ZERMELO-FRAENKEL AXIOMS, also known the axiom of regularity (Rubin 1967, Suppes 1972). In the formal language of SET THEORY, it states that

$$x \neq 0 \Rightarrow \exists y(y \in x \wedge y \bigcap x = \phi),$$

where $\Rightarrow$ means IMPLIES, $\exists$ means EXISTS, $\wedge$ means AND, $\cap$ denotes INTERSECTION, and ϕ is the EMPTY

SET (Mendelson 1997, p. 288). More descriptively, "every nonempty set is disjoint from one of its elements."

The axiom of foundation can also be stated as "A set contains no infinitely descending (membership) sequence," or "A set contains a (membership) minimal element," i.e., there is an element of the set that shares no member with the set (Ciesielski 1997, p. 37; Moore 1982, p. 269; Rubin 1967, p. 81; Suppes 1972, p. 53).

Mendelson (1958) proved that the equivalence of these two statements necessarily relies on the AXIOM OF CHOICE. The dual expression is called ϵ-induction, and is equivalent to the axiom itself (Itô 1986, p. 147).

Axiom of Infinity

The axiom of ZERMELO-FRAENKEL SET THEORY which asserts the existence of a set containing all the natural numbers,

$$\exists\, r(\varnothing \in x \ \vee \forall\, y \in x(y' \in x)).$$

Here, following von Neumann, $0 = \phi$, $1 = 0' = \{0\}$, $2 = 1' = \{0, 1\}$, $3 = 2' = \{0, 1, 2\}$, ...

Axiom of Regularity

AXIOM OF FOUNDATION

Axiom of Replacement

One of the ZERMELO-FRAENKEL AXIOMS which asserts the existence for any set a of a set x such that, for any y of a, if there exists a z satisfying $A(y, z)$, then such z exists in x. This axiom was introduced by Fraenkel.

See also ZERMELO-FRAENKEL AXIOMS

References

Axiom of Separation

The axiom of ZERMELO-FRAENKEL SET THEORY which asserts the existence for any set a and a formula $A(y)$ of a set x consisting of all elements of a satisfying $A(y)$,

$$\exists\, x\, \forall\, y(y \in x \equiv y \in a \ \wedge\ A(y)).$$

This axiom is also called the axiom of comprehension or axiom of subsets, and was introduced by Zermelo.

Axiom of the Empty Set

One of the ZERMELO-FRAENKEL AXIOMS which asserts the existence of the EMPTY SET ϕ. The axiom may be stated symbolically as

$$\exists\, x\, \forall\, y(!y \in x).$$

See also ZERMELO-FRAENKEL AXIOMS

References

Axiom of the Power Set

One of the ZERMELO-FRAENKEL AXIOMS which asserts the existence for any set a of the POWER SET x consisting of all the SUBSETS of a. The axiom may be stated symbolically as

$$\forall\, x\, \exists\, y(y \in x \equiv \forall\, z \in y(z \in a)).$$

Axiom of the Sum Set

The axiom of ZERMELO-FRAENKEL SET THEORY which asserts the existence for any set a of the sum (union) x of all sets that are elements of a. The axiom may be stated symbolically as

$$\exists x \, \forall y (y \in x \equiv \exists z \in a (y \in z)).$$

Axiom of the Unordered Pair

The axiom of ZERMELO-FRAENKEL SET THEORY which asserts the existence for any sets a and b of a set x having a and b as its only elements. x is called the unordered pair of a and b, denoted $\{a, b\}$. The axiom may be stated symbolically as

$$\exists x \, \forall y (y \in x \equiv y = a \vee y = b).$$

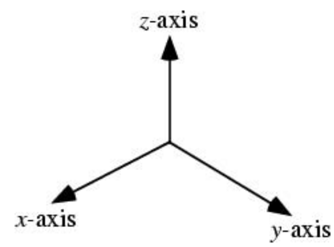
Axiomatic System

A logical system which possesses an explicitly stated SET of AXIOMS from which THEOREMS can be derived.

See also AXIOMATIC SET THEORY, COMPLETE AXIOMATIC THEORY, CONSISTENCY, MODEL THEORY, THEOREM

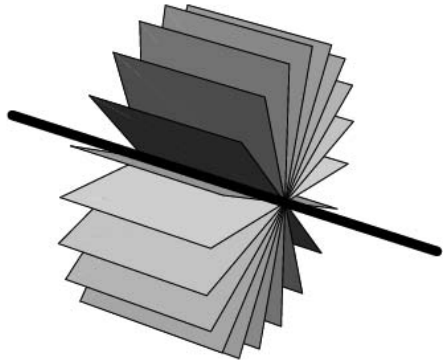
Axioms of Subsets

This entry contributed by NICOLAS BRAY



For any set theoretic formula $f(x, t_1, t_2, \ldots, t_n)$,

$$(\forall t_1)(\forall t_2)\cdots(\forall t_n)(\forall A)(\exists B)(\forall x).$$



$$(x \in B \Leftrightarrow x \in A \wedge f(x, t_1, \ldots, t_n))$$

In other words, for any formula and set A there is a SUBSET of A consisting exactly of those elements which satisfy the formula.

Axis

A LINE with respect to which a curve or figure is drawn, measured, rotated, etc.

The term is also used to refer to a LINE through a SHEAF OF PLANES (Woods 1961; Altshiller-Court 1979, p. 12).

See also ABSCISSA, BROCARD AXIS, HOMOLOGY AXIS, LEMOINE AXIS, LINE, MAJOR AXIS, MEDIAL AXIS, MINOR AXIS, ORDINATE, ORTHIC AXIS, PERSPECTIVE AXIS, RADICAL AXIS, REAL AXIS, SEMIMAJOR AXIS, SEMIMINOR AXIS, SHEAF OF PLANES, SIMILARITY AXIS, x-AXIS, y-AXIS, z-AXIS

Ax-Kochen Isomorphism Theorem

Let P be the SET of PRIMES, and let $\mathbb{Q}_p$ and $\mathbb{Z}_p(t)$ be the FIELDS of p-ADIC NUMBERS and formal POWER SERIES over $\mathbb{Z}_p = (0, 1, \ldots, p-1)$. Further, suppose that D is a "nonprincipal maximal filter" on P. Then $\prod_{p \in p} \mathbb{Q}_p / D$ and $\prod_{p \in q} \mathbb{Z}_p(t)/D$ are ISOMORPHIC.

Azimuthal Equidistant Projection

An azimuthal projection which is neither equal-area nor conformal. Let ϕ_1 and λ_0 be the latitude and longitude of the center of the projection, then the transformation equations are given by

$$x = k' \cos\phi \sin(\lambda - \lambda_0) \tag{1}$$

$$y = k'[\cos\phi_1 \sin\phi - \sin\phi_1 \cos\phi \cos(\lambda - \lambda_0)]. \tag{2}$$

Here,

$$k' = \frac{c}{\sin c} \tag{3}$$

and

$$\cos c = \sin\phi_1 \sin\phi + \cos\phi_1 \cos\phi \cos(\lambda - \lambda_0), \tag{4}$$

where c is the angular distance from the center. The inverse formulas are

$$\phi = \sin^{-1}\left(\cos c \sin\phi_1 + \frac{y \sin c \cos\phi_1}{c}\right) \tag{5}$$

and

$$\lambda = \begin{cases} \lambda_0 + \tan^{-1}\left(\frac{x \sin c}{c \cos\phi_1 \cos c - y \sin\phi_1 \sin c}\right) & \text{for } \phi_1 \neq \pm 90^\circ \\ \lambda_0 + \tan^{-1}\left(-\frac{x}{y}\right) & \text{for } \phi_1 = 90^\circ \\ \lambda_0 + \tan^{-1}\left(\frac{x}{y}\right) & \text{for } \phi_1 = -90^\circ. \end{cases} \tag{6}$$

with the angular distance from the center given by

$$c = \sqrt{x^2 + y^2}. \tag{7}$$

Azimuthal Projection

A map projection on which the azimuths of all points are shown correctly with respect to the center (Snyder 1987, p. 4). A plane tangent to one of the Earth's poles is the basis for polar azimuthal projection. The term "zenithal" is an older one for azimuthal projections (Hinks 1921, Lee 1944).

B

B2-Sequence

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Also called a SIDON SEQUENCE. An INFINITE SEQUENCE of POSITIVE INTEGERS

$$1 \leq b_1 < b_2 < b_3 < \ldots \tag{1}$$

such that all pairwise sums

$$b_i + b_j \tag{2}$$

for $i \leq j$ are distinct (Guy 1994). An example is 1, 2, 4, 8, 13, 21, 31, 45, 66, 81, 97, 123, 148, 182, 204, 252, 290, 361, ... (Sloane's A005282).

Zhang (1993, 1994) showed that

$$S(B2) \equiv \underset{\text{all B2 sequences}}{\text{SUP}} \sum_{k=1}^{\infty} \frac{1}{b_k} > 2.1597, \tag{3}$$

which has been increased to $S(B2) > 2.16086$ by R. Lewis using the sequence 1, 2, 4, 8, 13, 21, 31, 45, 66, 81, 97, 123, 148, 182, 204, 252, 291, 324, ... (Sloane's A046185). The definition can be extended to B_n-sequences (Guy 1994).

BAC-CAB Identity

The VECTOR TRIPLE PRODUCT identity

$$\mathbf{A} \times (\mathbf{B} \times \mathbf{C}) = \mathbf{B}(\mathbf{A} \cdot \mathbf{C}) - \mathbf{C}(\mathbf{A} \cdot \mathbf{B}).$$

This identity can be generalized to n-D

$$\mathbf{a}_2 \times \cdots \times \mathbf{a}_{n-1} \times (\mathbf{b}_1 \times \cdots \times \mathbf{b}_{n-1}) = (-1)^{n+1} \begin{vmatrix} \mathbf{b}_1 & \cdots & \mathbf{b}_{n-1} \\ \mathbf{a}_2 \cdot \mathbf{b}_1 & \cdots & \mathbf{a}_2 \cdot \mathbf{b}_{n-1} \\ \vdots & \ddots & \vdots \\ \mathbf{a}_{n-1} \cdot \mathbf{b}_1 & \cdots & \mathbf{a}_{n-1} \cdot \mathbf{b}_{n-1} \end{vmatrix}.$$

BAC-CAB Rule

BAC-CAB IDENTITY

Bachelier Function

BROWN FUNCTION

Bachet Equation

The DIOPHANTINE EQUATION

$$x^2 + k = y^3.$$

which is also an ELLIPTIC CURVE. The general equation is still the focus of ongoing study.

Bachet's Conjecture

LAGRANGE'S FOUR-SQUARE THEOREM

Bachet's Theorem

LAGRANGE'S FOUR-SQUARE THEOREM

Backhouse's Constant

Let $P(x)$ be defined as the POWER SERIES whose nth term has a COEFFICIENT equal to the nth PRIME,

$$P(x) \equiv \sum_{k=0}^{\infty} p_k x^k = 1 + 2x + 3x^2 + 5x^3 + 7x^4 + 11x^5 + \ldots,$$

and let $Q(x)$ be defined by

$$Q(x) = \frac{1}{P(x)} = \sum_{k=0}^{\infty} q_k x^k.$$

Then N. Backhouse conjectured that

$$\lim_{n \to \infty} \left| \frac{q_{n+1}}{q_n} \right| = 1.45607494858268967139959535111654\ldots.$$

This list was subsequently shown to exist by P. Flajolet.

Backtracking

A method of solving combinatorial problems by means of an algorithm which is allowed to run forward until a dead end is reached, at which point previous steps are retraced and the algorithm is allowed to run forward again. Backtracking can greatly reduce the amount of work in an exhaustive search. Backtracking is implemented as Backtrack[*s*, *partialQ*, *solutionQ*] in the *Mathematica* add-on package DiscreteMath`Combinatorica` (which can be loaded with the command << DiscreteMath`).

Backtracking also refers to a method of drawing FRACTALS by appropriate numbering of the corresponding tree diagram which does not require storage of intermediate results (Lauwerier 1991).

Backward Difference

The backward difference is a FINITE DIFFERENCE defined by

$$\nabla_p \equiv \nabla f_p \equiv f_p - f_{p-1}. \tag{1}$$

Higher order differences are obtained by repeated operations of the backward difference operator, so

$$\nabla_p^2 = \nabla(\nabla p) = \nabla(f_p - f_{p-1}) = \nabla f_p - \nabla f_{p-1} \tag{2}$$

$$= (f_p - f_{p-1}) - (f_{p-1} - f_{p-2})$$

$$= f_p - 2f_{p-1} + f_{p-2} \tag{3}$$

In general,

$$\nabla_p^k \equiv \nabla^k f_p \equiv \sum_{m=0}^{k} (-1)^m \binom{k}{m} f_{p-m}, \tag{4}$$

where $\binom{k}{m}$ is a BINOMIAL COEFFICIENT.

NEWTON'S BACKWARD DIFFERENCE FORMULA expresses f_p as the sum of the nth backward differences

$$f_p = f_0 + p\nabla_0 + \frac{1}{2!}\, p(p+1)\nabla_0^2 + \frac{1}{3!}\, p(p+1)(p+2)\nabla_0^3 + \ldots, \tag{5}$$

where ∇_0^n is the first nth difference computed from the difference table.

Baer Differential Equation

The Baer differential equation is given by

$$(x-a_1)(x-a_2)y''+\tfrac{1}{2}[2x-(a_1+a_2)]y'-(p^2x+q^2)y=0,$$

while the Baer "wave equation" is

$$(x-a_1)(x-a_2)y''+\tfrac{1}{2}[2x-(a_1+a_2)]y'-(k^2x^2-p^2x+q^2)y=0$$

(Moon and Spencer 1961, pp. 156–57; Zwillinger 1997, p. 121).

Bagging

See also RESAMPLING STATISTICS

Baguenaudier

A PUZZLE involving disentangling a set of rings from a looped double rod, originally used by French peasants to lock chests (Steinhaus 1983). The word "baguenaudier" means "time-waster" in French, and the puzzle is also called the Chinese rings or Devil's needle puzzle. ("Bague" also means "ring," but this appears to be an etymological coincidence. Interestingly, the bladder-senna tree is also known as "baguenaudier" in French.) Culin (1965) attributes the puzzle to Chinese general Hung Ming (A.D. 181–34), who gave it to his wife as a present to occupy her while he was away at the wars.

The solution of the baguenaudier is intimately related to the theory of GRAY CODES.

The minimum number of moves $a(n)$ needed for n rings is

$$a(n)=[\tfrac{2}{3}(2^n-1)]=\begin{cases}\tfrac{1}{3}(2^{n+1}-2) & n \text{ even}\\ \tfrac{1}{3}(2^{n+1}-1) & n \text{ odd},\end{cases} \quad (1)$$

where $\lceil x \rceil$ is the CEILING FUNCTION, giving 1, 2, 5, 10, 21, 42, 85, 170, 341, 682, ... (Sloane's A000975). The GENERATING FUNCTION for these numbers is

$$\frac{1}{(1-2x)(1-x^2)}=1+2x+5x^2+10x^3+21x^4+\ldots. \quad (2)$$

They are also given by the RECURRENCE RELATION

$$a(n)=a(n-1)+2a(n-2)+1 \quad (3)$$

with $a(1)=1$ and $a(2)=2$.

By simultaneously moving the two end rings, the number of moves for n rings can be reduced to

$$b(n)=\begin{cases}2^{n-1}-1 & n \text{ even}\\ 2^{n-1} & n \text{ odd},\end{cases} \quad (4)$$

giving 1, 1, 4, 7, 16, 31, 64, 127, 256, 511, ... (Sloane's A051049).

Defining the complexity of a solution as the minimal number of times the ring passes through the arc from the last ring to the base of the puzzle, the minimal complexity of a solution if 2^{n-1}, as conjectured by Kauffman (1996) and proved by Przytycki and Sikora (2000).

Bailey's Lemma

If, for $n \geq 0$,

$$\beta_n = \sum_{r=0}^{n} \frac{\alpha_r}{(q;\ q)_{n-r}(aq;\ q)_{n+r}}, \quad (1)$$

then

$$\beta'_n = \sum_{r=0}^{n} \frac{\alpha'_r}{(q;\ q)_{n-r}(aq;\ q)_{n+r}}, \quad (2)$$

where

$$\alpha'_r = \frac{(\rho_1;\ q)_r(\rho_2;\ q)_r(aq/\rho_1\rho_2)^r\alpha_r}{(aq/\rho_1;\ q)_r(aq/\rho_2;\ q)_r} \quad (3)$$

$$\beta'_n = \sum_{j\geq 0} \frac{(\rho_1;\ q)_j(\rho_2;\ q)_j(aq/\rho 1_1\rho_2;\ q)_{n-j}(aq/\rho_1\rho_2)^j\beta_j}{(q;\ q)_{n-j}(aq/\rho_1;\ q)_n(aq/\rho_2;\ q)_n}. \quad (4)$$

Bailey's Method

LAMBERT'S METHOD

Bailey's Theorem

Let $\Gamma(z)$ be the GAMMA FUNCTION, then

$$\left[\frac{\Gamma(m+\frac{1}{2})}{\Gamma(m)}\right]^2 \times \underbrace{\left[\frac{1}{m} + \left(\frac{1}{2}\right)^2 \frac{1}{m+1} + \left(\frac{1\cdot 3}{2\cdot 4}\right)^2 \frac{1}{m+2} + \ldots\right]}_{n}$$

$$= \left[\frac{\Gamma(n+\frac{1}{2})}{\Gamma(n)}\right]^2 \times \underbrace{\left[\frac{1}{n} + \left(\frac{1}{2}\right)^2 \frac{1}{n+1} + \left(\frac{1\cdot 3}{2\cdot 4}\right)^2 \frac{1}{n+2} + \ldots\right]}_{m}.$$

Writing the sums explicitly, Bailey's theorem states

$$\left[\frac{\Gamma(m+\frac{1}{2})}{\Gamma(m)}\right]^2 \sum_{k=0}^{n-1} \frac{1}{m+k} \left[\frac{(2k-1)!!}{(2k)!!}\right]^2$$

$$\left[\frac{\Gamma(n+\frac{1}{2})}{\Gamma(n)}\right]^2 \sum_{k=0}^{m-1} \frac{1}{n+k} \left[\frac{(2k-1)!!}{(2k)!!}\right]^2.$$

Bailey's Transformation

The very general transformation

$${}_9F_8\left[\begin{matrix} a, & 1+\frac{1}{2}a, & b, & c, & d \\ & \frac{1}{2}a & 1+a-b, & 1+a-c, & 1+a-d. \end{matrix}\right.$$

$$\left.\begin{matrix} e, & f, & g, & -m; \\ 1+a-e, & 1+a-f, & 1+a-g, & 1+a+m \end{matrix}\right]$$

$$= \frac{(1+a)_m(1+k-e)_m(1+k-f)_m(1+k-g)_m}{(1+k)_m(1+a-e)_m(1+a-f)_m(1+a-g)_m}$$

$$\times {}_9F_8\left[\begin{matrix} k, & 1+\frac{1}{2}k, & k+b-a, & k+c-a, & k+d-a, \\ & \frac{1}{2}k, & 1+a-b, & a+a-c, & 1+a-d, \end{matrix}\right.$$

$$\left.\begin{matrix} e, & f, & g, & -m; \\ 1+k-e, & 1+k-f, & 1+k-g, & 1+k+m \end{matrix}\right],$$

where $k = 1+2a-b-c-d$, and the parameters are subject to the restriction

$$b+c+d+e+f+g-m = 2+3a$$

(Bailey 1935, p. 27).

Bhatnagar (1995, pp. 17–8) defines the Bailey transform as follows. Let $(a;\ q)_n$ be the Q-POCHHAMMER SYMBOL, and let a be an indeterminate, and let the LOWER TRIANGULAR MATRICES $F = (F(n,\ k))$ and $F = (G(n,\ k))$ be defined as

$$F(n,\ k) = \frac{1}{(q;\ q)_{n-k}(aq;\ q)_{n+k}}$$

and

$$G(n,\ k) = \frac{(1-aq^{2n})(a;\ q)_{n+k}}{(1-a)(q;\ q)_{n-k}}(-1)^{n-k} q^{\binom{n-k}{2}}$$

Then F and G are MATRIX INVERSES.

Baire Category Theorem

A nonempty complete METRIC SPACE cannot be REPRESENTED AS the UNION of a COUNTABLE family of NOWHERE DENSE SUBSETS.

See also COUNTABLE SET, METRIC SPACE, NOWHERE DENSE

Baire Function

References

Feller, W. *An Introduction to Probability Theory and Its Applications, Vol. 2, 3rd ed.* New York: Wiley, pp. 104–06, 1971.

Baire Space

A TOPOLOGICAL SPACE X in which each SUBSET of X of the "first category" has an empty interior. A TOPOLOGICAL SPACE which is HOMEOMORPHIC to a complete METRIC SPACE is a Baire space.

Bairstow's Method

A procedure for finding the quadratic factors for the COMPLEX CONJUGATE ROOTS of a POLYNOMIAL $P(x)$ with REAL COEFFICIENTS.

$$\begin{aligned}[x-(a-ib)][x-(a-ib)] &= x^2+2ax+(a^2+b^2) \\ &\equiv x^2+Bx+C.\end{aligned} \tag{1}$$

Now write the original POLYNOMIAL as

$$P(x) = (x^2+Bx+C)Q(x)+Rx+S \tag{2}$$

$$R(B+\delta B,\ C+\delta C) \approx R(B,\ C) + \frac{\partial R}{\partial B}\,dB + \frac{\partial R}{\partial C}\,dC \tag{3}$$

$$S(B+\delta B,\ C+\delta C) \approx S(B,\ C) + \frac{\partial S}{\partial B}\,dB + \frac{\partial S}{\partial C}\,dC \tag{4}$$

$$\frac{\partial P}{\partial C} = 0 = (x^2+Bx+C)\frac{\partial Q}{\partial C} + Q(x) + \frac{\partial R}{\partial C} + \frac{\partial S}{\partial C} \tag{5}$$

$$-Q(x) = (x^2+Bx+C)\frac{\partial Q}{\partial C} + \frac{\partial R}{\partial C} + \frac{\partial S}{\partial C} \tag{6}$$

$$\frac{\partial P}{\partial B} = 0 = (x^2+Bx+C)\frac{\partial Q}{\partial B} + xQ(x) + \frac{\partial R}{\partial B} + \frac{\partial S}{\partial B} \tag{7}$$

$$-xQ(x) = (x^2+Bx+C)\frac{\partial Q}{\partial B} + \frac{\partial R}{\partial B} + \frac{\partial S}{\partial B}. \tag{8}$$

Now use the 2-D NEWTON'S METHOD to find the simultaneous solutions.

Baker's Dozen

The number 13.

See also 13, DOZEN

Baker's Map

The MAP

$$x_{n+1} = 2\mu x_n, \tag{1}$$

where x is computed modulo 1. A generalized Baker's map can be defined as

$$x_{n+1} = \begin{cases} \lambda_a x_n & y_n < \alpha \\ (1-\lambda_b) + \lambda_b x_n & y_n > \alpha \end{cases} \tag{2}$$

$$y_{n+1} = \begin{cases} \dfrac{y_n}{\alpha} & y_n < \alpha \\ \dfrac{y_n - \alpha}{\beta} & y_n > \alpha, \end{cases} \tag{3}$$

where $\beta \equiv 1 - \alpha$, $\lambda_a + \lambda_b \leq 1$, and x and y are computed mod 1. The $q = 1$ Q-DIMENSION is

$$D_1 = 1 + \frac{\alpha \ln\left(\dfrac{1}{\alpha}\right) + \beta \ln\left(\dfrac{1}{\beta}\right)}{\alpha \ln\left(\dfrac{1}{\gamma_a}\right) + \beta \ln\left(\dfrac{1}{\gamma_b}\right)}. \tag{4}$$

If $\lambda_a = \lambda_b$, then the general Q-DIMENSION is

$$D_q = 1 + \frac{1}{q-1} \frac{\ln(\alpha^q + \beta^q)}{\ln \lambda_a}. \tag{5}$$

Balanced Incomplete Block Design

BLOCK DESIGN

Ball

The n-ball, denoted $\mathbb{B}^n$, is the interior of a SPHERE $\mathbb{S}^{n-1}$, and sometimes also called the n-DISK. (Although physicists often use the term "SPHERE" to mean the solid ball, mathematicians definitely do not!) Let $\mathrm{Vol}(\mathbb{B}^n)$ denote the volume of an n-D ball of RADIUS r. Then

$$\sum_{n=0}^{\infty} \mathrm{Vol}(B^n) = e^{\pi r^2}[1 + \mathrm{erf}(r\sqrt{\pi})],$$

where $\mathrm{erf}(x)$ is the ERF function.

References

Freden, E. Problem 10207. "Summing a Series of Volumes." *Amer. Math. Monthly* **100**, 882, 1993.

Ball Line Picking

Given an n-ball $\mathbb{B}^n$ of radius R, find the distribution of the lengths s of the lines determined by two points chosen at random within the ball. The probability distribution of lengths is given by

$$P_n(s) = n\,\frac{s^{n-1}}{R^n}\,I_x(\tfrac{1}{2}(n+1), \tfrac{1}{2}), \tag{1}$$

where

$$x \equiv 1 - \frac{s^2}{4R^2} \tag{2}$$

and

$$I_x(p,\ q) = \frac{B(x;\ p,\ q)}{B(p,\ q)} \tag{3}$$

is a REGULARIZED BETA FUNCTION, with $B(x;\ p,\ q)$ is an INCOMPLETE BETA FUNCTION and $B(p,\ q)$ is a BETA FUNCTION (Tu and Fischbach 2000). The first few are

$$P_1(s) = \frac{1}{R} - \frac{s}{2R} \tag{4}$$

$$P_2(s) = \frac{4s}{\pi R^2}\cos^{-1}\left(\frac{s}{2R}\right) - \frac{2s^2}{\pi R^3}\sqrt{1 - \frac{s^2}{4R^2}} \tag{5}$$

$$P_3(s) = \frac{3s^2}{R^3} - \frac{9s^3}{4R^4} + \frac{3s^5}{16R^6} \tag{6}$$

$$P_4(s) = \frac{8s^3}{\pi R^4}\cos^{-1}\left(\frac{s}{2R}\right) - \frac{8s^4}{3\pi R^5} \times \left(1 - \frac{s^2}{4R^2}\right)^{3/2} - \frac{4s^4}{\pi R^5}\sqrt{-1\ \frac{s^2}{4R^2}}. \tag{7}$$

The average lengths are given by

$$\bar{s}_1 = \frac{2R}{3} \tag{8}$$

$$\bar{s}_2 = \frac{128R}{45\pi} \tag{9}$$

$$\bar{s}_3 = \frac{36R}{35} \tag{10}$$

$$\bar{s}_4 = \frac{16384R}{4725\pi}. \tag{11}$$

Ball Triangle Picking

The determination of the probability for obtaining an OBTUSE TRIANGLE by picking three points at random in the unit DISK was generalized by Hall (1982) to the n-dimensional BALL. Buchta (1986) subsequently gave closed form evaluations for Hall's integrals. Let P_n be the probability that that three points chosen independently and uniformly from the n-BALL

form an ACUTE TRIANGLE, then

$$P_{2m+1} = -\frac{1}{2} - 2^{2m-1}\frac{\binom{2m}{m}\binom{4m}{2m}}{\binom{4m}{m}\binom{6m+1}{2m}} + m\binom{2m}{m}^2 2^{2m}$$

$$\times \sum_{k=0}^{m} \frac{\binom{2k}{k}}{\binom{2m+k}{m}\binom{4m+2k}{2m+k}}$$

$$\times \frac{3m+k+1}{(m+k)(3m+2k+1)} \quad (1)$$

$$P_{2m+2} = \frac{1}{4} - \frac{3}{2^{2m+4}}\frac{\binom{4m+4}{m+1}}{\binom{2m+2}{m+1}} + \frac{2^{4m}}{\binom{2m}{m}\pi^2}$$

$$\times \left[\frac{1}{(2m+1)^2\binom{2m}{m}}\right.$$

$$\left. + \sum_{k=0}^{m} \frac{2^{2k}(3m+k-3)}{(2k+1)\binom{2k}{k}\binom{2m+k}{m}\binom{2m+k+2}{m}}\right], \quad (2)$$

the first few being

$$P_2 = \frac{4}{\pi^2} - \frac{1}{8} \approx 0.280285 \quad (3)$$

$$P_3 = \tfrac{33}{70} \approx 0.471429 \quad (4)$$

$$P_4 = \frac{256}{45\pi^2} + \frac{1}{32} \approx 0.607655 \quad (5)$$

$$P_5 = \frac{1415}{2002} \approx 0.706793 \quad (6)$$

$$P_6 = \frac{2048}{315\pi^2} + \frac{31}{256} \approx 0.779842 \quad (7)$$

$$P_7 = \frac{231161}{277134} \approx 0.834113 \quad (8)$$

$$P_8 = \frac{4194304}{606375\pi^2} + \frac{89}{512} \approx 0.874668 \quad (9)$$

$$P_9 = \frac{9615369}{10623470} \approx 0.905106. \quad (10)$$

The case P_2 corresponds to DISK TRIANGLE PICKING case.

Ballantine

BORROMEAN RINGS

Ballieu's Theorem

Let the CHARACTERISTIC POLYNOMIAL of an $n \times n$ COMPLEX MATRIX A be written in the form

$$P(\lambda) = |\lambda 1 - \mathsf{A}| = \lambda^n + b_1\lambda^{n-1} + b_2\lambda^{n-2} + \ldots + b_{n-1}\lambda + b_n.$$

Then for any set $\boldsymbol{\mu} = (\mu_1, \mu_2, \ldots, \mu_n)$ of POSITIVE numbers with $\mu_0 = 0$ and

$$M^- = \max_{0 \le k \le n-1} \frac{\mu_k + \mu_n |b_{n-k}|}{\mu_{k+1}},$$

all the EIGENVALUES λ_i (for $i = 1, ..., n$) lie on the CLOSED DISK $|z| \le M^-$ in the COMPLEX PLANE.

Ballot Problem

Suppose A and B are candidates for office and there are $2n$ voters, n voting for A and n for B. In how many ways can the ballots be counted so that A is always ahead of or tied with B? The solution is a CATALAN NUMBER C_n.

A related problem also called "the" ballot problem is to let A receive a votes and B b votes with $a > b$. This version of the ballot problem then asks for the probability that A stays ahead of B as the votes are counted (Vardi 1991). The solution is $(a-b)/(a+b)$, as first shown by M. Bertrand (Hilton and Pedersen 1991). Another elegant solution was provided by André (1887) using the so-called ANDRÉ'S REFLECTION METHOD.

The problem can also be generalized (Hilton and Pedersen 1991). Furthermore, the TAK FUNCTION is connected with the ballot problem (Vardi 1991).

Banach Algebra

A Banach algebra is an ALGEBRA B over a FIELD F endowed with a NORM $\|\cdot\|$ such that B is a BANACH SPACE under the norm $\|\cdot\|$ and multiplication is continuous in the sense that if $x, y \in B$ then $\|xy\| \leq \|x\|\|y\|$. Continuity of multiplication is the most important property.

F is frequently taken to be the COMPLEX NUMBERS in order to assure that the SPECTRUM fully characterizes an OPERATOR (i.e., the spectral theorems for normal or compact normal operators do not, in general, hold in the SPECTRUM over the REAL NUMBERS).

If B has a unit, then $x \in B$ is invertible if and only if $\hat{x}(\phi) \neq 0$ for all ϕ, where $x \mapsto \hat{x}$ is the GELFAND TRANSFORM.

Banach Measure

An "AREA" which can be defined for every set–even those without a true geometric AREA–which is rigid and finitely additive.

Banach Space

A Banach space is a COMPLETE VECTOR SPACE B with a norm $\|v\|$. Its topology is determined by its norm, and the vector space operations of addition and scalar multiplication are required to be continuous. Two norms $\langle v \rangle_1$ and $\langle v \rangle_2$ are called equivalent if they give the same TOPOLOGY, which is equivalent to the existence of constants c and C such that

$$c\langle v \rangle_1 \leq \langle v \rangle_2 \leq C\langle v \rangle_1 \quad (1)$$

holds for all v. In the finite dimensional case, all norms are equivalent. An infinite dimensional space can have many different norms.

A basic example is n dimensional EUCLIDEAN SPACE with the Euclidean norm. Usually, the notion of Banach space is only used in the infinite dimensional setting, typically as a VECTOR SPACE of functions. For example, the set of continuous functions on the real line with the norm of a function f given by

$$\|f\| = sup_{x \in \mathbb{R}} |f(x)| \quad (2)$$

is a Banach space, where sup denotes the SUPREMUM.

On the other hand, the set of continuous functions on the unit interval [0, 1] with the norm of a function f given by

$$\|f\| = \int_0^1 |f(x)|\, dx \qquad (3)$$

is not a Banach space because it is not complete. For instance, the CAUCHY SEQUENCE of functions

$$f_n \begin{cases} 1 & \text{for } x \leq 1/2 \\ \frac{1}{2}n + 1 - nx & \text{for } x \leq 1/2 + 1/n \\ 0 & \text{for } x > 1/2 + 1/n \end{cases} \qquad (4)$$

does not converge to a continuous function.

HILBERT SPACES with their norm given by the inner product are examples of Banach spaces. While a HILBERT SPACE is always a Banach space, the converse need not hold. Therefore, it is possible for a Banach space not to have a norm given by an inner product. For instance, the supremum norm cannot be given by an INNER PRODUCT.

Banach-Hausdorff-Tarski Paradox

BANACH-TARSKI PARADOX

Banach-Steinhaus Theorem

UNIFORM BOUNDEDNESS PRINCIPLE

Banach-Tarski Paradox

First stated in 1924, the Banach-Tarski paradox states that it is possible to dissect a BALL into six pieces which can be reassembled by rigid motions to form two balls of the same size as the original. The number of pieces was subsequently reduced to five by R. M. Robinson in 1944, although the pieces are extremely complicated. (Actually, four pieces are sufficient as long as the single point at the center is neglected.) A generalization of this theorem is that any two bodies in $\mathbb{R}^3$ which do not extend to infinity and each containing a ball of arbitrary size can be dissected into each other (i.e., they are EQUIDECOMPOSABLE).

See also BALL, CIRCLE SQUARING, DISSECTION, EQUIDECOMPOSABLE

Bandwidth

The bandwidth of a MATRIX $M = (m_{ij})$ is the maximum value of $|i - j|$ such that m_{ij} is nonzero.

The bandwidth of a GRAPH G is the minimum bandwidth among ADJACENCY MATRICES of GRAPHS isomorphic to G. Bounds for the bandwidth of a graph have been considered by (Harper 1964), and the bandwidth of the k-cube was determined by Harper (1966).

Bankoff Circle

The circle through the cusp of the ARBELOS and the tangent points of the first Pappus circle, which is congruent to the two ARCHIMEDES' CIRCLES. If $AB = r$

and $AC = 1$, then the radius of the Bankoff circle is

$$R = \tfrac{1}{2} r(1-r).$$

Banzhaf Power Index

The number of ways in which a group of n with weights $\Sigma_{i=1}^{n} w_i = 1$ can change a losing coalition (one with $\Sigma\, w_i < 1/2$)) to a winning one, or vice versa. It was proposed by the lawyer J. F. Banzhaf in 1965.

Bar

A bar (also called an overbar) is a horizontal line written above a mathematical symbol to give it some special meaning. If the bar is placed over a single symbol, as in $\bar{x}$ (voiced "x-bar"), it is sometimes called a macron. If placed over multiple symbols (especially in the context of a radical), it is known as a vinculum. Common uses of the bar symbol include the following.

1. The mean

$$\bar{x} \equiv \frac{1}{n} \sum_{i=1}^{n} x_i$$

of a set $\{x_i\}_{i=1}^{n}$.

2. The complex conjugate

$$\bar{z} \equiv x - iy$$

for $z = x + iy$.

3. The complement $\bar{F}$ of a set F.

4. A set stripped of any structure besides order, hence the order type of the set.

In conventional typography, "bar" refers to a vertical (instead a horizontal) bar, such as those used to denote absolute value ($|x|$) (Bringhurst 1997, p. 271).

See also Double Bar, Hat, Macron, Vinculum

Bar Graph

Bar Chart

Bar Graph Polygon

A column-convex self-avoiding polygon which contains the bottom edge of its minimal bounding rectangle. The anisotropic perimeter and area generating function

$$G(x,\ y,\ q) = \sum m \geq 1 \sum_{n \geq 1} \sum_{a \geq a} C(m,\ n,\ a) x^m y^n q^a,$$

where $C(m,n,a)$ is the number of polygons with $2m$ horizonal bonds, $2n$ vertical bonds, and area a, has been computed exactly for the bar graph polygons (Bousquet-Mélou 1996, Bousquet-Mélou *et al.* 1999). The anisotropic area and perimeter generating function $G(x,\ y,\ q)$ and partial generating functions

$H_m(y, q)$, connected by

$$G(x, y, q) = \sum_{m \geq 1} H_m(y, q) x^m,$$

satisfy the self-reciprocity and inversion relations

$$H_m(1/y, 1/q) = \frac{(-1)^m}{yq^m} H_m(y, q)$$

and

$$G(x, y, q) - yG(-xq, 1/y, 1/q) = 0$$

(Bousquet-Mélou *et al.* 1999).

Barnes' G-Function

Barnes' G-function is defined by

$$G(z+1)$$

$$\equiv (2\pi)^{z/2} e^{-\left[z(z+1)+\gamma z^2\right]/2} \prod_{n=1}^{\infty} \left[\left(1+\frac{z}{n}\right)^n e^{-z+z^2/(2n)} \right] \qquad (1)$$

where γ is the EULER-MASCHERONI CONSTANT (Whittaker and Watson 1990, p. 264; Voros 1987). It is an ENTIRE FUNCTION analogous to $1/\Gamma(z)$, where $\Gamma(z)$ is the GAMMA FUNCTION, except that it has order 2 instead of 1.
This is an ANALYTIC CONTINUATION of the G-function defined in the construction of the GLAISHER-KINKELIN CONSTANT

$$G(n) \equiv \frac{[\Gamma(n)]^{n-1}}{K_n}, \qquad (2)$$

where

$$K_n \equiv 0^0 1^1 2^2 3^3 \cdots (n-1)^{n-1}, \qquad (3)$$

which has the special values

$$G(n) = \begin{cases} 0 & \text{if } n=0,\ -1,\ -2, \ldots \\ 1 & \text{if } n=1 \\ 0!1!2!\cdots(n-2)! & \text{if } n=2,\ 3,\ 4\ldots \end{cases} \qquad (4)$$

for INTEGER n. This function is what Sloane and Plouffe (1995) call the SUPERFACTORIAL, and the first few values for $n = 1, 2, \ldots$ are 1, 1, 1, 2, 12, 288, 34560, 24883200, 125411328000, 5056584744960000, ... (Sloane's A000178).

Barnes' G-function satisfies the functional equation

$$G(z+1) = \Gamma(z) G(z), \qquad (5)$$

and has the TAYLOR SERIES

$$\ln G(1+z) = \tfrac{1}{2}[\ln(2\pi) - 1]z - (1+\gamma)\frac{z^2}{2}$$

$$+ \sum_{n=3}^{\infty} (-1)^{n-1} \zeta(n-1) \frac{z^n}{n} \qquad (6)$$

in $|z|<1$. It also gives an analytic solution to the finite product

$$\prod_{i=1}^{n} \Gamma(k+i) = \frac{G(n+k+1)}{G(k+1)}, \qquad (7)$$

has the identities

$$\frac{[\Gamma(n)]^n}{G(n)} = K(n), \qquad (8)$$

where $K(n)$ is the K-FUNCTION, and the equivalent reflection formulas

$$\frac{G'(z+1)}{G(z+1)} = \tfrac{1}{2}\ln(2\pi) - \tfrac{1}{2} - z + z\,\frac{\Gamma'(z)}{\Gamma(z)} \qquad (9)$$

$$\ln\left[\frac{G(1-z)}{G(1+z)}\right] = \pi \int_0^z z \cot(\pi z)\, dz - z \ln(2\pi) \qquad (10)$$

$$\frac{G(\frac{1}{2}+z)}{(\frac{1}{2}-z)} = \frac{(2\pi)^2}{\Gamma(\frac{1}{2}+z)} \sqrt{\frac{\pi}{\cos(\pi z)}} \exp\left[\pi \int_0^z \tan(\pi z)\, dz\right] \qquad (11)$$

(Voros 1987; Whittaker and Watson 1990, p. 264). A Stirling-like ASYMPTOTIC SERIES as $z \to \infty$ is given by

$$\ln G(1+z) \sim z^2\left(\tfrac{1}{2}\ln z - \tfrac{3}{4}\right) + \tfrac{1}{2}\ln(2\pi)z - \tfrac{1}{12}\ln z - \ln A$$

$$+ \mathcal{O}\left(\frac{1}{z}\right) \qquad (12)$$

(Voros 1987).
$G(n)$ has the special values

$$G(\tfrac{1}{2}) = \pi^{-1/4} \exp\left[\tfrac{1}{24}\ln 2 + \tfrac{3}{2}\zeta'(-1)\right] \qquad (13)$$

$$= A^{-3/2}\pi^{-1/4} e^{1/8} 2^{1/24} \qquad (14)$$

$$G(\tfrac{3}{2}) = A^{-3/2}\pi^{1/4} e^{1/8} 2^{1/24}, \qquad (15)$$

and so on, where $\zeta'(-1)$ is the derivative of the RIEMANN ZETA FUNCTION evaluated at -1 and the GLAISHER-KINKELIN CONSTANT A is defined by

$$A = \exp[\tfrac{1}{12} - \zeta'(-1)] = 1.28242712\ldots \qquad (16)$$

(Voros 1987). *Mathematica* 4.0 implements the constant A as `Glaisher`. In general, for odd $n = 2k+1$,

$$G(\tfrac{1}{2}(2k+1)) = c_k \frac{A^{-3/2}\pi^{-(2k-3)/4}e^{1/8}2^{1/24}}{2^{(k-1)(k-2)/2}}, \tag{17}$$

where

$$c_k = \prod_{i=1}^{k-2} \frac{2^i\Gamma(\frac{1}{2}+i)}{\sqrt{\pi}} \tag{18}$$

for $k > 1$, of which the first few terms are 1, 1, 1, 3, 45, 4725 4465125, ... (Sloane's A057863).

Barnes' G-function can arise in spectral functions in mathematical physics (Voros 1987).

Another G-FUNCTION is defined by Erdélyi *et al.* (1981, p. 20) as

$$G(z) \equiv \psi_0\left(\tfrac{1}{2}+hz\right) - \psi_0(\tfrac{1}{2}z), \tag{19}$$

where $\psi_0(z)$ is the DIGAMMA FUNCTION. An unrelated pair of functions are denoted g_n and G_n and are known as RAMANUJAN g- AND G-FUNCTIONS.

Barnes' Lemma

If a CONTOUR in the COMPLEX PLANE is curved such that it separates the increasing and decreasing sequences of POLES, then

$$\frac{1}{2\pi i}\int_{-i\infty}^{i\infty} \Gamma(\alpha+s)\Gamma(\beta+s)\Gamma(\gamma-s)\Gamma \times(\delta-s)\,ds \frac{\Gamma(\alpha+\gamma)\Gamma(\alpha+\delta)\Gamma(\beta+\gamma)\Gamma(\beta+\delta)}{\Gamma(\alpha+\beta+\gamma+\delta)},$$

where $\Gamma(z)$ is the GAMMA FUNCTION (Bailey 1935, p. 7).

Barnes' second lemma states that

$$\int \frac{2}{2\pi i} \frac{\Gamma(\alpha_1+s)\Gamma(\alpha_2+s)\Gamma(\alpha_3+s)\Gamma(1-\beta_1-s)\Gamma(-s)\,ds}{\Gamma(\beta_2+s)}$$
$$= \frac{\Gamma(\alpha_1)\Gamma(\alpha_2)\Gamma(\alpha_3)\Gamma(1-\beta_1+\alpha_1)\Gamma(1-\beta_1+\alpha_2)\Gamma(1-\beta_1+\alpha_3)}{\Gamma(\beta_2-\alpha_1)\Gamma(\beta_2-\alpha_2)\Gamma(\beta_2-\alpha_3)}$$

provided that $\beta_1+\beta_2 = \alpha_1+\alpha_2+\alpha_3+1$ (Bailey 1935, pp. 42–3).

Barnsley's Fern

The ATTRACTOR of the ITERATED FUNCTION SYSTEM given by the set of "fern functions"

$$f_1(x, y) = \begin{bmatrix} 0.85 & 0.04 \\ -0.04 & 0.85 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} + \begin{bmatrix} 0.00 \\ 1.60 \end{bmatrix} \quad (1)$$

$$f_2(x, y) = \begin{bmatrix} -0.15 & 0.28 \\ 0.26 & 0.24 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} + \begin{bmatrix} 0.00 \\ 0.44 \end{bmatrix} \quad (2)$$

$$f_3(x, y) = \begin{bmatrix} 0.20 & -0.26 \\ 0.23 & 0.22 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} + \begin{bmatrix} 0.00 \\ 1.60 \end{bmatrix} \quad (3)$$

$$f_4(x, y) = \begin{bmatrix} 0.00 & 0.00 \\ 0.00 & 0.16 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} \quad (4)$$

(Barnsley 1993, p. 86; Wagon 1991). These AFFINE TRANSFORMATIONS are contractions. The tip of the fern (which resembles the black spleenwort variety of fern) is the fixed point of f_1, and the tips of the lowest two branches are the images of the main tip under f_2 and f_3 (Wagon 1991).

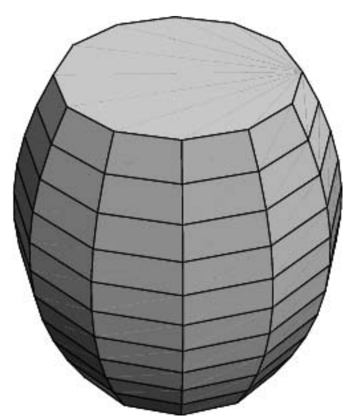
Barrel

A SOLID OF REVOLUTION composed of parallel circular top and bottom with a common axis and a side formed by a smooth curve symmetrical about the midplane.

For sides consisting of an arc of an ELLIPSE, the equation of the side is given by

$$x(z) = r_2\sqrt{1 - \frac{(z - \frac{1}{2}h)^2}{a^2}}, \quad (1)$$

with $x(0) = r_1$. Solving for a gives



$$a = \frac{hr_2}{2\sqrt{r_2^2 - r_1^2}}, \quad (2)$$

so the sides have equation

$$x(z) = \sqrt{r_2^2 + \frac{(r_1 - r_2)(r_1 + r_2)(h - 2z)^2}{h^2}}. \quad (3)$$

Using the equation for a SOLID OF REVOLUTION then gives

$$V = \pi\int_0^h [x(z)]^2 dx = \tfrac{1}{3}\pi h(2r_2^2 + r_1^2). \quad (4)$$

For sides consisting of a PARABOLIC SEGMENT, the equation of the side is given by

$$x(z) = r_2 + a(z - \tfrac{1}{2}h)^2 \quad (5)$$

with $x(0) = r_1$. Solving for a gives

$$a = \frac{4(r_1 - r_2)}{h^2}, \quad (6)$$

so the sides have equation

$$x(z) = r_2 + \frac{(r_1 - r_2)(h - 2z)^2}{h^2}. \quad (7)$$

Using the equation for a SOLID OF REVOLUTION then gives

$$V = \pi \int_0^h [x(z)]^2 dx = \tfrac{1}{15}\pi h(3r_1^2 + 4r_1 r_2 + 8r_2^2). \quad (8)$$

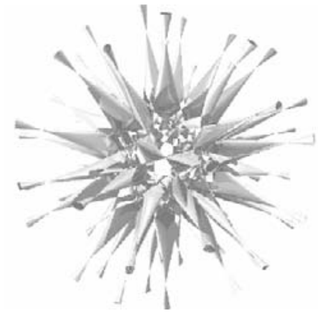
Barrier

A number n is called a barrier of a number-theoretic function $f(m)$ if, for all $m < n$, $m + f(m) \leq n$. Neither the TOTIENT FUNCTION $\phi(n)$ nor the DIVISOR FUNCTION $\sigma(n)$ has a barrier.

Let $U \subseteq \mathbb{C}$ be an OPEN SET and $x_0 \in \partial U$, then a function $b : \bar{U} \to \mathbb{R}$ is called a barrier for U at a point x_0 if

1. b is continuous,
2. b is SUBHARMONIC on U,
3. $b|_{\partial U} \leq 0$,
4. $\{z \in \partial U : b(z) = 0\} = \{z_0\}$

(Krantz 1999, pp. 100–01).



See also SUBHARMONIC FUNCTION

Barth Decic

The Barth decic is a DECIC SURFACE in complex three-dimensional projective space having the maximum possible number of ORDINARY DOUBLE POINTS (345). It is given by the implicit equation

$$\begin{aligned} 8(x^2 - \phi^4 y^2)(y^2 - \phi^4 z^2)(z^2 - \phi^4 x^2) \\ \times (x^4 + y^4 + z^4 - 2x^2y^2 - 2x^2z^2 - 2y^2z^2) + (3 + 5\phi) \\ \times (x^2 + y^2 + z^2 - w^2)^2 [x^2 + y^2 + z^2 - (2 - \phi)w^2]^2 w^2 \\ = 0, \end{aligned}$$

where ϕ is the GOLDEN MEAN and w is a parameter (Endraß, Nordstrand), taken as $w = 1$ in the above plot. The Barth decic is invariant under the ICOSAHEDRAL GROUP.

Barth Sextic

The Barth-sextic is a SEXTIC SURFACE in complex three-dimensional projective space having the maximum possible number of ORDINARY DOUBLE POINTS (65). Of these, 20 nodes are at the vertices of a regular DODECAHEDRON of side length $2/\phi$, and 30 are at the midpoints of the edges of a concentric DODECAHEDRON of side length $2/\phi^2$, where ϕ is the GOLDEN RATIO. The surface was discovered by W. Barth in 1994, and is given by the implicit equation

$$4(\phi^2x^2-y^2)(\phi^2y^2-z^2)(\phi^2z^2-x^2)-(1+2\phi)$$

$$\times(x^2+y^2+z^2-w^2)^2w^2=0,$$

where ϕ is the GOLDEN MEAN, and w is a parameter (Endraß, Nordstrand), taken as $w=1$ in the above plot.

The Barth sextic is invariant under the ICOSAHEDRAL GROUP. Under the map

$$(x,\ y,\ z,\ w)\to(x^2,\ y^2,\ z^2,\ w^2),$$

the surface is the eightfold cover of the CAYLEY CUBIC (Endraß).

Bartlett Function

The APODIZATION FUNCTION

$$f(x)=1-\frac{|x|}{a} \tag{1}$$

which is a generalization of the one-argument TRIANGLE FUNCTION. Its FULL WIDTH AT HALF MAXIMUM is a.

It has INSTRUMENT FUNCTION

$$I(x)=\int_{-a}^{a}e^{-2\pi ikx}\left(1-\frac{|x|}{a}\right)dx$$

$$=\int_{-a}^{0}e^{-2\pi ikx}\left(1+\frac{x}{a}\right)dx$$

$$+\int_{0}^{a}e^{-2\pi ikx}\left(1-\frac{x}{a}\right)dx. \tag{2}$$

Letting $x'\equiv -x$ in the first part therefore gives

$$\int_{-a}^{0}e^{-2\pi ikx}\left(1+\frac{x}{a}\right)dx=\int_{a}^{0}e^{-2\pi ikx'}\left(1-\frac{x'}{a}\right)(-dx')$$

$$=\int_{0}^{a}e^{-2\pi ikx}\left(1-\frac{x}{a}\right)dx. \tag{3}$$

Rewriting (2) using (3) gives

$$I(x)=(e^{2\pi ikx}+e^{-2\pi ikx})\left(1-\frac{x}{a}\right)dx$$

$$=2\int_{0}^{a}\cos(2\pi kx)\left(1-\frac{x}{a}\right)dx. \tag{4}$$

Integrating the first part and using the integral

$$\int x\cos(bx)\,dx=\frac{1}{b^2}\cos(bx)+\frac{x}{b}\sin(bx) \tag{5}$$

for the second part gives

$$I(x)=2\left[\frac{\sin(2\pi kx)}{2\pi k}-\frac{1}{a}\left\{\frac{1}{4\pi^2k^2}\cos(2\pi kx)+\frac{x}{2\pi k}\sin(2\pi kx)\right\}\right]_0^a$$

$$=2\left\{\left[\frac{\sin(2\pi ka)}{2\pi k}-0\right]-\frac{1}{a}\left[\frac{\cos(2\pi ka)-1}{4\pi^2k^2}+\frac{a\sin(2\pi ka)}{2\pi k}\right]\right\}$$

$$=\frac{1}{2\pi^2ak^2}[\cos(2\pi ka)-1]=a\frac{\sin^2(\pi ka)}{\pi^2k^2a^2}=a\,\mathrm{sinc}^2(\pi ka) \tag{6}$$

where sinc x is the SINC FUNCTION. The peak (in units of a) is 1. The function $I(x)$ is always positive, so there are no NEGATIVE sidelobes. The extrema are given by letting $\beta\equiv\pi ka$ and solving

$$\frac{d}{d\beta}\left(\frac{\sin\beta}{\beta}\right)^2=2\frac{\sin\beta}{\beta}\frac{\sin\beta-\beta\cos\beta}{\beta^2}=0 \tag{7}$$

$$\sin\beta(\sin\beta-\beta\cos\beta)=0 \tag{8}$$

$$\sin\beta-\beta\cos\beta=0 \tag{9}$$

$$\tan\beta=\beta. \tag{10}$$

Solving this numerically gives $\beta=4.49341$ for the first maximum, and the peak POSITIVE sidelobe is 0.047190. The full width at half maximum is given by

setting $x \equiv \pi k a$ and solving

$$\operatorname{sinc}^2 x = \tfrac{1}{2} \tag{11}$$

for $x_{1/2}$, yielding

$$x_{1/2} = \pi k_{1/2} a = 1.39156. \tag{12}$$

Therefore, with $L \equiv 2a$,

$$\text{FWHM} = 2k_{1/2} = \frac{0.885895}{a} = \frac{1.77179}{L}. \tag{13}$$

Barycentric Coordinates

Barycentric coordinates are triples of numbers (t_1, t_2, t_3) corresponding to masses placed at the vertices of a reference triangle $\Delta A_1A_2A_3$. These masses then determine a point P, which is the centroid of the three masses, and is identified with coordinates (t_1, t_2, t_3). The vertices of the triangle are given by $(1, 0, 0)$, $(0, 1, 0)$, and $(0, 0, 1)$. Barycentric coordinates were discovered by Möbius in 1827 (Coxeter 1969, p. 217; Fauvel *et al.* 1993).

To find the barycentric coordinates for an arbitrary point P, find t_2 and t_3 from the point Q at the intersection of the line A_1P with the side A_2A_3, and then determine t_1 as the mass at A_n that will balance a mass t_2+t_3 at Q, thus making P the centroid (left figure). Furthermore, the areas of the triangles ΔA_1A_2P, ΔA_1A_3P, and ΔA_2A_3P are proportional to the barycentric coordinates t_3, t_2, and t_1 of P (right figure; Coxeter 1969, p. 217).

Barycentric coordinates are homogeneous, so

$$(t_1, t_2, t_3) = (\mu t_1, \mu t_2, \mu t_3) \tag{1}$$

for $\mu \neq 0$. Barycentric coordinates normalized so that they become the actual areas of the subtriangles are called homogeneous barycentric coordinates, and barycentric coordinates normalized so that

$$t_1 + t_2 + t_3 = 1, \tag{2}$$

so that the coordinates give the areas of the subtriangles *normalized by the area of the original triangle* are called AREAL COORDINATES (Coxeter 1969, p. 218). Barycentric and areal coordinates can provide particular elegant proofs of geometric theorems such as ROUTH'S THEOREM, CEVA'S THEOREM, and MENELAUS' THEOREM (Coxeter 1969, pp. 219–21).

The homogeneous barycentric coordinates corresponding to TRILINEAR COORDINATES $\alpha : \beta : \gamma$ are $(a\alpha, b\beta, c\gamma)$, and the TRILINEAR COORDINATES corresponding to homogeneous barycentric coordinates (t_1, t_2, t_3) are $t_1/a : t_2/b : t_3/c$. The homogeneous barycentric coordinates for some common triangle centers are summarized in the following table, where $s = (a+b+c)/2$ is the SEMIPERIMETER.

triangle center	homogeneous barycentric coordinates
CENTROID (TRIANGLE)	$(1, 1, 1)$
CIRCUMCENTER	$(a^2(b^2+c^2-a^2), b^2(c^2+a^2-b^2), c^3(a^2+b^2-c^2))$
EXCENTERS	$(-a, b, c)$
	$(a, -b, c)$
	$(a, b, -c)$
GERGONNE POINT	$((s-b)(s-c), (s-c)(s-a), (s-a)(s-b))$
INCENTER	(a, b, c)
NAGEL POINT	$(s-a, s-b, s-c)$
ORTHOCENTER	$((a^2+b^2-c^2)(c^2+a^2-b^2), (b^2+c^2-a^2)(a^2+b^2-c^2)),$
	$(c^2+a^2-b^2)(b^2+c^2-a^2))$
SYMMEDIAN POINT	(a^2, b^2, c^2)

In barycentric coordinates, a line has a linear homogeneous equation. In particular, the line joining points (r_1, r_2, r_3) and (s_1, s_2, s_3) has equation

$$\begin{vmatrix} r_1 & r_2 & r_3 \\ s_1 & s_2 & s_3 \\ t_1 & t_2 & t_3 \end{vmatrix} \tag{3}$$

(Loney 1962, pp. 39 and 57; Coxeter 1969, p. 219; Bottema 1982). If the vertices P_i of a triangle $\Delta P_1P_2P_3$ have barycentric coordinates (x_i, y_i, z_i), then the area of the triangle is

$$\Delta P_1P_2P_3 = \begin{vmatrix} x_1 & y_1 & z_1 \\ x_2 & y_2 & z_2 \\ x_3 & y_3 & z_3 \end{vmatrix} \Delta ABC \tag{4}$$

(Bottema 1982, Yiu 2000).

Base (Logarithm)

The number used to define the number system in which a LOGARITHM is computed. In general, the logarithm of a number x in base b is written $\log_b x$. The symbol $\log x$ is an abbreviation regrettably used both for the COMMON LOGARITHM $\log_{10} x$ (by engineers and physicists and indicated on pocket calculators) and for the NATURAL LOGARITHM $\log_e x$ (by mathematicians). $\ln x$ denotes the NATURAL LOGARITHM $\log_e x$ (as used by engineers and physicists and indicated on pocket calculators), and $\lg x$ denotes $\log_2 x$. In this work, the notations $\log x = \log_{10} x$ and $\ln x = \log_e x$ are used.

To convert between logarithms in different bases, the formula

$$\log_b x = \frac{\ln x}{\ln b}$$

can be used.

See also COMMON LOGARITHM, e, LG, LN, LOGARITHM, NAPIERIAN LOGARITHM, NATURAL LOGARITHM, BASE (NUMBER)

Base (Neighborhood System)

A base for a neighborhood system of a point x is a collection N of OPEN SETS such that x belongs to every member of N, and any OPEN SET containing x also contains a member of N as a SUBSET.

Base (Number)

A REAL NUMBER x can be represented using any INTEGER number b as a base (sometimes also called a RADIX or SCALE). The choice of a base yields to a representation of numbers known as a NUMBER SYSTEM. In base b, the DIGITS 0, 1, ..., $b-1$ are used (where, by convention, for bases larger than 10, the symbols A, B, C, ...are generally used as symbols representing the DECIMAL numbers 10, 11, 12, ...).

Base	Name
2	BINARY
3	TERNARY
4	QUATERNARY
5	Quinary
6	Senary
7	Septenary
8	OCTAL
9	Nonary
10	DECIMAL
11	Undenary
12	DUODECIMAL
16	HEXADECIMAL
20	VIGESIMAL
60	SEXAGESIMAL

Let the base b representation of a number x be written

$$(a_n a_{n-1} \ldots a_0 . a_{-1} \ldots)_b, \tag{1}$$

(e.g., 123.456_{10}), then the index of the leading DIGIT needed to represent the number is

$$n \equiv \lfloor \log_b x \rfloor, \tag{2}$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION. Now, recursively compute the successive DIGITS

$$a_i = \left\lfloor \frac{r_i}{b^i} \right\rfloor, \tag{3}$$

where $r_n \equiv x$ and

$$r_{i-1} = r_i - a_i b^i \tag{4}$$

for $i = n$, $n-1$, ..., 1, 0, ... This gives the base b representation of x. Note that if x is an INTEGER, then i need only run through 0, and that if x has a fractional part, then the expansion may or may not terminate. For example, the HEXADECIMAL representation of 0.1 (which terminates in DECIMAL notation) is the infinite expression $0.19999\ldots_h$.

Some number systems use a mixture of bases for counting. Examples include the Mayan calendar and the old British monetary system (in which ha'pennies, pennies, threepence, sixpence, shillings, half crowns, pounds, and guineas corresponded to units of 1/2, 1, 3, 6, 12, 30, 240, and 252, respectively).

Knuth (1998) has considered using TRANSCENDENTAL bases. This leads to some rather unfamiliar results, such as equating π to 1 in "base π," $\pi = 10_\pi$.

Base Curve

DIRECTRIX (RULED SURFACE)

Base Manifold

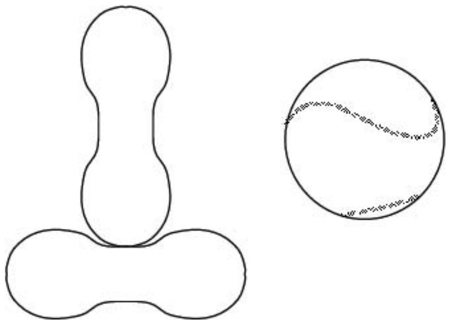
The base manifold in a BUNDLE is analogous to the domain for a set of functions. In fact, a bundle, by definition, comes with a map to the base manifold, often called π or projection.

For example, the base manifold to the TANGENT BUNDLE of a MANIFOLD M is the MANIFOLD M. A VECTOR FIELD is a function from the manifold to the TANGENT BUNDLE, with the restriction that every point gets mapped to a vector at that point. In general, a BUNDLE has SECTIONS, at least locally, which are maps from the base manifold to the BUNDLE.

See also BUNDLE, MANIFOLD, SECTION (BUNDLE), TANGENT BUNDLE, VECTOR BUNDLE

Base Space

The SPACE B of a FIBER BUNDLE given by the MAP $f: E \to B$, where E is the TOTAL SPACE of the FIBER BUNDLE.



See also FIBER BUNDLE, TOTAL SPACE

Baseball

The numbers three and four appear prominently in the game of baseball. There are three strikes for an out, and three outs per inning, $3 \cdot 3 = 9$ innings in a game, giving $3^3 = 27$ outs per game (assuming no extra innings). In addition, there are 3×3 players per team. Four balls are needed for a walk. The number of bases can either be regarded as three (excluding HOME PLATE) or four (including it).

See also BASEBALL COVER, HOME PLATE

Baseball Cover

A pair of identical plane regions (mirror symmetric about two perpendicular lines through the center) which can be stitched together to form a baseball (or tennis ball). A baseball has a CIRCUMFERENCE of 9 1/8 inches. The practical consideration of separating the regions far enough to allow the pitcher a good grip requires that the "neck" distance be about 1 3/16 inches. The baseball cover was invented by Elias Drake as a boy in the 1840s. (Thompson's attribution of the current design to trial and error development by C. H. Jackson in the 1860s is apparently unsubstantiated, as discovered by George Bart.)

One way to produce a baseball cover is to draw the regions on a SPHERE, then cut them out. However, it is difficult to produce two identical regions in this manner. Thompson (1996) gives mathematical expressions giving baseball cover curves both in the plane and in 3-D. J. H. Conway has humorously proposed the following "baseball curve conjecture:" no two definitions of "the" baseball curve will give the same answer unless their equivalence was obvious from the start.

See also BASEBALL, HOME PLATE, TENNIS BALL THEOREM, YIN-YANG

Basic Polynomial Sequence

A POLYNOMIAL SEQUENCE $p_n(x)$ is called the basic polynomial sequence for a DELTA OPERATOR Q if

1. $p_0(x) = 1$,
2. $p_n(0) = 0$ for all $n > 0$,
3. $Qp_n(x) = np_{n-1}(x)$.

If $p_n(x)$ is a basic polynomial sequence for some DELTA OPERATOR Q, then it is a BINOMIAL-TYPE SEQUENCE of polynomials. Furthermore, if $p_n(x)$ is a BINOMIAL-TYPE SEQUENCE of polynomials, then it is a basic polynomial sequence for some DELTA OPERATOR.

See also BINOMIAL-TYPE SEQUENCE, DELTA OPERATOR, POLYNOMIAL SEQUENCE, UMBRAL OPERATOR

References

Rota, G.-C.; Kahaner, D.; Odlyzko, A. "On the Foundations of Combinatorial Theory. VIII: Finite Operator Calculus." *J. Math. Anal. Appl.* **42**, 684–60, 1973.

Basin of Attraction

The set of points in the space of system variables such that initial conditions chosen in this set dynamically evolve to a particular ATTRACTOR.

See also WADA BASIN

Basis

The word basis can arise in several different contexts. Speaking in general terms, an object is "generated" by a basis in whatever manner is appropriate. For example, a VECTOR SPACE can have a BASIS which SPANS the vector space by finite LINEAR COMBINATIONS.

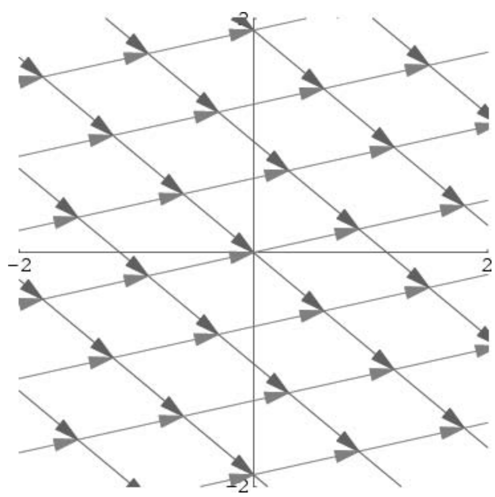
See also BASIS POINT, BASIS (TOPOLOGY), BASIS (VECTOR SPACE), HAMEL BASIS, HILBERT BASIS, ORTHONORMAL BASIS, VECTOR BASIS

Basis (Topology)

If X is a SET, a basis for a TOPOLOGY on X is a collection B of SUBSETS of X (called basis elements) satisfying the following properties.

1. For each $x \in X$, there is at least one basis element B containing X.
2. If x belongs to the intersection of two basis elements B_1 and B_2, then there is a basis element B_3 containing x such that $B_3 \subset B_1 \cap B_2$.

References



Munkres, J. R. *Topology: A First Course.* Englewood Cliffs, NJ: Prentice-Hall, 1975.

Basis (Vector Space)

A basis of a VECTOR SPACE V is defined as a subset $v_1, \ldots, v_n$ of vectors in V that are LINEARLY INDEPENDENT and SPAN V. Consequently, if $(v_1, v_2, \ldots, v_n)$ is a list of vectors in V, then these vectors form a basis if and only if every $v \in V$ can be uniquely written as

$$v = a_1 b_1 + a_2 b_2 + \ldots + a_n b_n,$$

where $a_1, \ldots, a_\pi$ are elements of $\mathbb{R}$ or $\mathbb{C}$. A VECTOR SPACE V will have many different bases, but there are always the same number of basis vectors in each of them. The number of basis vectors in V is called the DIMENSION of V. Every spanning list in a vector space can be reduced to a basis of the vector space.

The simplest example of a basis is the standard basis in $\mathbb{R}^n$ consisting of the coordinate axes. For example, in $\mathbb{R}^2$, the standard basis consists of two VECTORS $e_1 = (1, 0)$ and $e_2 = (0, 1)$. Any VECTOR $w = (a, b)$ can be written uniquely as the LINEAR COMBINATION $w = ae_1 + be_2$. Indeed, a vector is defined by its coordinates. The VECTORS $v_1 = (3, 2)$ and $v_2 = (2, 1)$ are also a basis for $\mathbb{R}^2$ because any VECTOR $w = (a, b)$ can be uniquely written as $w = (-a + 2b)v_1 + (2a - 3b)v_2$. The above figure shows $(0.6, -0.5)n + (0.9, .02)m$, which are linear combinations of the basis $\{(0.6, -0.5), (0.9, 0.2)\}$.

Here is a *Mathematica* function which will return the coefficients a_i given a basis v_i.

```
LinearCombination[v_List?MatrixQ, w_] :=
   LinearSolve[Transpose[v], w]
```

For example, LinearCombo[{{1, 2}, {0, 1}}, {-3, 4}] yields $\{3, -2\}$, since $3(-1, 2) - 2(0, 1) = (-3, 4)$.

When a VECTOR SPACE is infinite dimensional, then a basis exists, as long as one assumes the AXIOM OF CHOICE. A subset of the basis which is linearly independent and whose span is DENSE is called a complete set, and is similar to a basis. When V is a HILBERT SPACE, a complete set is called a HILBERT BASIS.

See also BASIS, DIMENSION, HILBERT BASIS, LINEAR COMBINATION, ORTHONORMAL BASIS, SPAN (VECTOR SPACE), VECTOR SPACE

Basis Element

A collection B of subsets of a set X forming a topological BASIS.

See also BASIS (TOPOLOGY)

Basis Point

One basis point is defined to be 0.01 PERCENTAGE POINTS. Therefore, a change of 0.21% could also be expressed as a change by 21 "basis points."

See also PERCENTAGE POINT

Basis Theorem

HILBERT BASIS THEOREM

Basler Problem

The problem of analytically finding the value of $\zeta(2)$, where $\zeta(n)$ is the RIEMANN ZETA FUNCTION.

Bauer's Identical Congruence

Let $T(m)$ denote the set of the $\phi(m)$ numbers less than and RELATIVELY PRIME to m, where $\phi(n)$ is the TOTIENT FUNCTION. Define

$$f_m(x) = \prod_{t \in T(m)} (x - t). \tag{1}$$

Then a theorem of Lagrange states that

$$f_p(x) \equiv x^{\phi(p)} - 1 \pmod{p} \tag{2}$$

for p an ODD PRIME (Hardy and Wright 1979, p. 98). This can be generalized as follows. Let p be an ODD PRIME DIVISOR of m and p^a the highest POWER which divides m, then

$$f_m(x) \equiv (x^{p-1} - 1)^{\phi(m)/(p-1)} \pmod{p^a} \tag{3}$$

and, in particular,

$$f_{p^a}(x) \equiv (x^{p-1}-1)^{p^{a-1}} \pmod{p^a}. \tag{4}$$

Now, if $m > 2$ is EVEN and 2^a is the highest POWER of 2 that divides m, then

$$f_m(x) \equiv (x^2-1)^{\phi(m)/2} \pmod{2^a} \tag{5}$$

and, in particular,

$$f_{2^a}(x) \equiv (x^2-1)^{2^{a-2}} \pmod{2^a}. \tag{6}$$

Bauer's Theorem

Let $m \geq 3$ be an integer and let

$$f(x) = \sum_{k=0}^{n} a_k x^{n-k}$$

be an INTEGER POLYNOMIAL that has at least one real zero. Then $f(x)$ has infinitely many PRIME DIVISORS that are not congruent to 1 (mod m) (Nagell 1951, p. 168).

Baxter-Hickerson Function

In April 1999, Ed Pegg conjectured on `sci.math` that there were only finitely many ZEROFREE cubes, to which D. Hickerson responded with a counterexample. A few days later, Lew Baxter posted the slightly simpler example

$$f(n) = \tfrac{1}{3}(2 \cdot 10^{5n} - 10^{4n} + 2 \cdot 10^{3n} + 10^{2n} + 10^n + 1),$$

which produces numbers whose cubes lack zeros. The first few terms for $n = 0, 1, \ldots$ are 2, 64037, 6634003367, 666334000333667, ... (Sloane's A052427). Primes occur for $n = 0, 1, 7, 133, \ldots$ (Sloane's A051832) with no others ≤ 470 (Weisstein, Dec. 15, 1999), corresponding to 2, 64037, ... (Sloane's A051833).

Bayes' Formula

BAYES' THEOREM

Bayes' Theorem

Let A and B_j be SETS. CONDITIONAL PROBABILITY requires that

$$P(A \cap B_j) = P(A)P(B_j|A), \tag{1}$$

where $\cap$ denotes INTERSECTION ("and"), and also that

$$P(A \cap B_j) = P(B_j \cap A) = P(B_j)P(A|B_j). \tag{2}$$

Therefore,

$$P(B_j|A) = \frac{P(B_j)P(A|B_j)}{P(A)}. \tag{3}$$

Now, let

$$S \equiv \bigcup_{i=1}^{N} A_i, \tag{4}$$

so A_i is an event in S and $A_i \cap A_j = \emptyset$ for $i \neq j$, then

$$A = A \cap S = A \cap \left(\bigcup_{i=1}^{N} A_i \right) = \bigcup_{i=1}^{N} (A \cap A_i) \tag{5}$$

$$P(A) = P\left(\bigcup_{i=1}^{N} (A \cap A_i) \right) = \sum_{i=1}^{N} P(A \cap A_i). \tag{6}$$

But this can be written

$$P(A) = \sum_{i=1}^{N} P(A_i)P(A|A_i), \tag{7}$$

so

$$P(A_i|A) = \frac{P(A_i)P(A|A_i)}{\sum_{j=1}^{N} P(A_j)P(A|A_j)} \tag{8}$$

(Papoulis 1984, pp. 38–9).

Bayesian Analysis

A statistical procedure which endeavors to estimate parameters of an underlying distribution based on the observed distribution. Begin with a "PRIOR DISTRIBUTION" which may be based on anything, including an assessment of the relative likelihoods of parameters or the results of non-Bayesian observations. In practice, it is common to assume a UNIFORM DISTRIBUTION over the appropriate range of values for the PRIOR DISTRIBUTION.

Given the PRIOR DISTRIBUTION, collect data to obtain the observed distribution. Then calculate the LIKELIHOOD of the observed distribution as a function of parameter values, multiply this likelihood function by the PRIOR DISTRIBUTION, and normalize to obtain a unit probability over all possible values. This is called the POSTERIOR DISTRIBUTION. The MODE of the distribution is then the parameter estimate, and "probability intervals" (the Bayesian analog of CONFIDENCE INTERVALS) can be calculated using the standard procedure. Bayesian analysis is somewhat controversial because the validity of the result depends on how valid the PRIOR DISTRIBUTION is, and this cannot be assessed statistically.

Beal's Conjecture

A generalization of FERMAT'S LAST THEOREM which states that if $a^x + b^y = c^z$, where a, b, c, x, y, and z are POSITIVE INTEGERS and $x, y, z > 2$, then a, b, and c have a common factor. The conjecture was announced in Mauldin (1997), and a cash prize of $75,000 has been offered for its proof or a counterexample.

Beam Detector

N.B. A detailed online essay by S. Finch was the starting point for this entry.

A "beam detector" for a given curve C is defined as a curve (or set of curves) through which every LINE tangent to or intersecting C passes. The shortest 1-arc beam detector, illustrated in the upper left figure, has length $L_1 = \pi + 2$. The shortest known 2-arc beam detector, illustrated in the right figure, has angles

$$\theta_1 \approx 1.286 \text{ rad} \quad (1)$$

$$\theta_2 \approx 1.191 \text{ rad}, \quad (2)$$

given by solving the simultaneous equations

$$2 \cos \theta_1 - \sin(\tfrac{1}{2}\theta_2) = 0 \quad (3)$$

$$\tan(\tfrac{1}{2}\theta_1)\cos(\tfrac{1}{2}\theta_2) + \sin(\tfrac{1}{2}\theta_2)[\sec^2(\tfrac{1}{2}\theta_2) + 1] = 2. \quad (4)$$

The corresponding length is

$$\begin{aligned} L_2 &= 2\pi - 2\theta_1 - \theta_2 + 2\tan\left(\tfrac{1}{2}\theta_1\right) + \sec\left(\tfrac{1}{2}\theta_2\right) - \cos\left(\tfrac{1}{2}\theta_2\right) \\ &\quad + \tan\left(\tfrac{1}{2}\theta_1\right)\sin\left(\tfrac{1}{2}\theta_2\right) \\ &= 4.8189264563\ldots. \quad (5) \end{aligned}$$

A more complicated expression gives the shortest known 3-arc length $L_3 = 4.799891547\ldots$. Finch defines

$$L = \inf_{n \geq 1} L_n \quad (6)$$

as the beam detection constant, or the TRENCH DIGGERS' CONSTANT. It is known that $L \geq \pi$.

Beast Number

The occult "number of the beast" associated in the Bible with the Antichrist. It has figured in many numerological studies. It is mentioned in Revelation 13:18: "Here is wisdom. Let him that hath understanding count the number of the beast: for it is the number of a man; and his number is 666." The origin of this number is not entirely clear, although it may be as simple as the number containing the concatenation of one symbol of each type (exclude $M = 1000$) in ROMAN NUMERALS: $DCLXVI = 666$ (Wells 1986).

The first few numbers containing the beast number in their digits are 666, 1666, 2666, 3666, 4666, 5666, 6660, ... (Sloane's A051003).

The beast number has several interesting properties which numerologists may find particularly interesting (Keith 1982–3). In particular, the beast number is equal to the sum of the squares of the first 7 PRIMES

$$2^2 + 3^2 + 5^2 + 7^2 + 11^2 + 13^2 + 17^2 = 666, \quad (1)$$

satisfies the identity

$$\phi(666) = 6 \cdot 6 \cdot 6, \quad (2)$$

where ϕ is the TOTIENT FUNCTION, as well as the sum

$$\sum_{i=1}^{6 \cdot 6} i = 666 \quad (3)$$

which is the sum of numbers on a roulette wheel (Emanouilidis 1998). Emanouilidis (1998) also gives additional more obscure connections between 666 and the numbers on a roulette wheel. The number 666 is a sum and difference of the first three 6th POWERS,

$$666 = 1^6 - 2^6 + 3^6 \quad (4)$$

(Keith). Another curious identity is that there are exactly two ways to insert "+" signs into the sequence 123456789 to make the sum 666, and exactly one way for the sequence 987654321,

$$\begin{aligned} 666 &= 1 + 2 + 3 + 4 + 567 + 89 \\ &= 123 + 456 + 78 + 9 \end{aligned} \quad (5)$$

$$666 = 9 + 87 + 6 + 543 + 21 \quad (6)$$

(Keith). 666 is a REPDIGIT, and is also a TRIANGULAR NUMBER

$$T_{6 \cdot 6} = T_{36} = 666. \quad (7)$$

In fact, it is the largest REPDIGIT TRIANGULAR NUMBER (Bellew and Weger 1975–6). 666 is also a SMITH NUMBER. The first 144 DIGITS of $\pi - 3$, where π is PI, add to 666. In addition $144 = (6 + 6) \times (6 + 6)$ (Blatner 1997). Finally,

$$\sum_{i=0}^{5} 2048^i \equiv 691 \pmod{666}. \quad (8)$$

A number OF THE FORM 2^i which contains the digits of the beast number "666" is called an APOCALYPTIC NUMBER, and a number having 666 digits is called an APOCALYPSE NUMBER.

Beatty Sequence

The Beatty sequence is a SPECTRUM SEQUENCE with an IRRATIONAL base. In other words, the Beatty sequence corresponding to an IRRATIONAL NUMBER θ is given by $\lfloor\theta\rfloor$, $\lfloor 2\theta\rfloor$, $\lfloor 3\theta\rfloor$, ..., where $\lfloor x\rfloor$ is the FLOOR FUNCTION. If α and β are POSITIVE IRRATIONAL NUMBERS such that

$$\frac{1}{\alpha} + \frac{1}{\beta} = 1,$$

then the Beatty sequences $\lfloor\alpha\rfloor$, $\lfloor 2\alpha\rfloor$, ... and $\lfloor\beta\rfloor$, $\lfloor 2\beta\rfloor$, ... together contain all the POSITIVE INTEGERS without repetition.

The sequences for particular values of α and β are given in the following table (Sprague 1963; Wells 1986, pp. 35 and 40), where ϕ is the GOLDEN RATIO.

parameter	Sloane	sequence
$\alpha = \sqrt{2}$	A001951	1, 2, 4, 5, 7, 8, 9, 11, 12, ...
$\beta = 2 + \sqrt{2}$	A001952	3, 6, 10, 13, 17, 20, 23, 27, 30, ...
$\alpha = \sqrt{3}$	A022838	1, 3, 5, 6, 8, 10, 12, 13, 15, 17, ...
$\beta = \frac{1}{2}(3 + \sqrt{3})$	A054406	2, 4, 7, 9, 11, 14, 16, 18, 21, 23, 26, ...
$\alpha = e$	A022843	2, 5, 8, 10, 13, 16, 19, 21, 24, 27, 29, ...
$\beta = e/(e-1)$	A054385	1, 3, 4, 6, 7, 9, 11, 12, 14, 15, 17, 18, ...
$\alpha = \pi$	A022844	3, 6, 9, 12, 15, 18, 21, 25, 28, 31, 34, ...
$\beta = \pi/(\pi-1)$	A054386	1, 2, 4, 5, 7, 8, 10, 11, 13, 14, 16, 17, 19, ...
$\alpha = \phi$	A000201	1, 3, 4, 6, 8, 9, 11, 12, 14, 16, 17, 19, 21, ...
$\beta = \phi^2$	A001950	2, 5, 7, 10, 13, 15, 18, 20, 23, 26, 28, 31, 34, ...

Beauzamy and Dégot's Identity

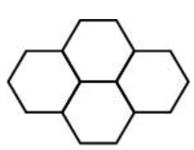
For P, Q, R, and S POLYNOMIALS in n variables

$$[P \cdot Q,\ R \cdot S] = \sum_{i_1, \ldots, i_n \geq 0} \frac{A}{i_1! \cdots i_n!},$$

where

$$A \equiv [R^{(i_1, \ldots, i_n)}(D_1, \ldots, D_n) Q(x_1, \ldots, x_n) \times P^{(i_1, \ldots, i_n)}(D_1, \ldots, D_n) S(x_1, \ldots, x_n)],$$

$D_i = \partial / \partial x_i$ is the DIFFERENTIAL OPERATOR, $[X, Y]$ is the BOMBIERI INNER PRODUCT, and



$$P^{(i_1, \ldots, i_n)} = D_1^{i_1} \cdots D_n^{i_n} P.$$

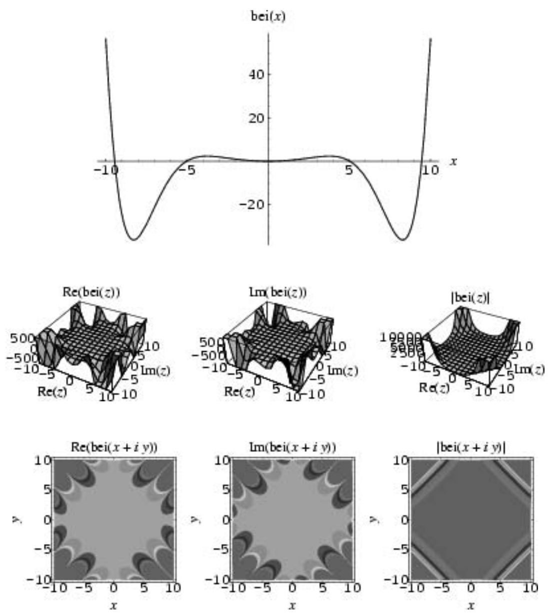
Bei

The IMAGINARY PART of



$$J_\nu(xe^{3\pi i/4}) = \mathrm{ber}_\nu(x) + i\ \mathrm{bei}_\nu(x). \qquad (1)$$

The function $\mathrm{bei}_\nu(x)$ has the series expansion

$$\mathrm{bei}_\nu(x) = (\tfrac{1}{2}x)^\nu \sum_{k=0}^{\infty} \frac{\sin[(\frac{3}{4}\nu + \frac{1}{2}k)\pi]}{k!\Gamma(\nu + k + 1)} (\tfrac{1}{4}x^2)^k, \qquad (2)$$

where $\Gamma(x)$ is the GAMMA FUNCTION (Abramowitz and

Stegun 1972, p. 379).

The special case $\nu = 0$ gives

$$J_0\left(i\sqrt{i}\,x\right) \equiv \text{ber}(x) + i\ \text{bei}(x), \tag{3}$$

where $J_0(x)$ is the zeroth order BESSEL FUNCTION OF THE FIRST KIND. The function $\text{bei}_0(x) \equiv \text{bei}(x)$ has the series expansion

$$\text{bei}(x) \equiv \sum_{n=0}^{\infty} \frac{(-1)^n (\frac{1}{2}x)^{2+4n}}{[(2n+1)!]^2}. \tag{4}$$

Bell Curve

GAUSSIAN DISTRIBUTION, NORMAL DISTRIBUTION

Bell Number

The number of ways a SET of n elements can be PARTITIONED into nonempty SUBSETS is called a BELL NUMBER and is denoted B_n. For example, there are five ways the numbers $\{1, 2, 3\}$ can be partitioned: $\{\{1\},\{2\},\{3\}\}$, $\{\{1, 2\},\{3\}\}$, $\{\{1, 3\},\{2\}\}$, $\{\{1\}, \{2, 3\}\}$, and $\{\{1, 2, 3\}\}$, so $B_3 = 5$. $B_0 = 1$ and the first few Bell numbers for $n = 1, 2, \ldots$ are 1, 2, 5, 15, 52, 203, 877, 4140, 21147, 115975, ... (Sloane's A000110).

Bell numbers are closely related to CATALAN NUMBERS. The diagram above shows the constructions giving $B_3 = 5$ and $B_4 = 15$, with line segments representing elements in the same SUBSET and dots representing subsets containing a single element (Dickau). The INTEGERS B_n can be defined by the sum

$$B_n = \sum_{k=1}^{n} S(n,\ k), \tag{1}$$

where $S(n,\ k)$ is a STIRLING NUMBER OF THE SECOND KIND, i.e., as the STIRLING TRANSFORM of the sequence 1, 1, 1, ...

The Bell number are given by the EXPONENTIAL GENERATING FUNCTION

$$e^{e^n - 1} = \sum_{n=0}^{\infty} \frac{B_n}{n!}\ x^n. \tag{2}$$

The Bell numbers can also be generated using the BELL TRIANGLE, using the RECURRENCE RELATION

$$B_{n+1} = \sum_{k=0}^{n} B_k \binom{n}{k}, \tag{3}$$

where $\binom{a}{b}$ is a BINOMIAL COEFFICIENT, or using the formula of Comtet (1974)

$$B_n = \left\lceil e^{-1} \sum_{m=1}^{2n} \frac{m^n}{m!} \right\rceil, \tag{4}$$

where $\lceil x \rceil$ denotes the CEILING FUNCTION.

The Bell number B_n is also equal to $\phi_n(1)$, where $\phi_n(x)$ is an EXPONENTIAL POLYNOMIAL. DOBINSKI'S FORMULA gives the nth Bell number

$$B_n = \frac{1}{e} \sum_{k=0}^{\infty} \frac{k^n}{k!}. \tag{5}$$

Lovász (1993) showed that this formula gives the asymptotic limit

$$B_n \sim n^{-1/2} [\lambda(n)]^{n+1/2} e^{\lambda(n)-n-1}, \tag{6}$$

where $\lambda(n)$ is defined implicitly by the equation

$$\lambda(n)\log[\lambda(n)] = n. \tag{7}$$

A variation of DOBINSKI'S FORMULA gives

$$B_n = \sum_{k=1}^{n} \frac{k^n}{k!} \sum_{j=0}^{n-k} \frac{(-1)^j}{j!} \tag{8}$$

(Pitman 1997). de Bruijn (1958) gave the asymptotic formula

$$\frac{\ln B_n}{n} = \ln n - \ln\ln n - 1 + \frac{\ln\ln n}{\ln n} + \frac{1}{\ln n} + \frac{1}{2}\left(\frac{\ln\ln n}{\ln n}\right)^2 + \mathcal{O}\left[\frac{\ln\ln n}{(\ln n)^2}\right] \tag{9}$$

TOUCHARD'S CONGRUENCE states

$$B_{p+k} \equiv B_k + B_{k+1} \pmod{p}, \tag{10}$$

when p is PRIME. The only PRIME Bell numbers for $n \leq 1000$ are B_2, B_3, B_7, B_{13}, B_{42}, and B_{55}. The Bell numbers also have the curious property that

$$\begin{vmatrix} B_0 & B_1 & B_2 & \cdots & B_n \\ B_1 & B_2 & B_3 & \cdots & B_{n+1} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ B_n & B_{n+1} & B_{n+2} & \cdots & B_{2n} \end{vmatrix} = \prod_{i=1}^{n} i! \tag{11}$$

(Lenard 1986), where the product is simply a SUPERFACTORIAL, the first few of which for $n = 0, 1, 2, \ldots$ are 1, 1, 2, 12, 288, 34560, 24883200, ... (Sloane's A000178).

Bell Polynomial

The Bell polynomial are defined by

$$B_{n,k}(x_1, x_2, \ldots) = \sum_{\substack{j_1+j_2+\cdots=k \\ j_1+2j_2+\cdots=n}} \frac{n!}{j_1!j_2!\cdots} \left(\frac{x_1}{1!}\right)^{j_1} \left(\frac{x_2}{2!}\right)^{j_2} \cdots.$$

They have GENERATING FUNCTION

$$\sum_{k=0}^{\infty} \frac{b_k(x;\ x_1, x_2, \ldots)}{k!} t^k = e^x \left(\sum_{k=1}^{\infty} \frac{x_k}{k!} t^k\right).$$

Beltrami Differential Equation

For a MEASURABLE FUNCTION μ, the Beltrami differential equation is given by

$$f_{\tilde{z}} = \mu f_z,$$

where f_z is a PARTIAL DERIVATIVE and $\tilde{z}$ denotes the COMPLEX CONJUGATE of z.

See also QUASICONFORMAL MAP

Beltrami Field

A VECTOR FIELD **u** satisfying the vector identity

$$\mathbf{u} \times (\nabla \times \mathbf{u}) = \mathbf{0}$$

where $\mathbf{A} \times \mathbf{B}$ is the CROSS PRODUCT and $\nabla \times \mathbf{A}$ is the CURL is said to be a Beltrami field.

See also DIVERGENCELESS FIELD, IRROTATIONAL FIELD, SOLENOIDAL FIELD

Beltrami Identity

An identity in CALCULUS OF VARIATIONS discovered in 1868 by Beltrami. The EULER-LAGRANGE DIFFERENTIAL EQUATION is

$$\frac{\partial f}{\partial y} - \frac{d}{dx}\left(\frac{\partial f}{\partial y_x}\right) = 0. \quad (1)$$

Now, examine the DERIVATIVE of f with respect to x

$$\frac{df}{dx} = \frac{\partial f}{\partial y} y_x + \frac{\partial f}{\partial y_x} y_{xx} + \frac{\partial f}{\partial x}. \quad (2)$$

Solving for the $\partial f / \partial y$ term gives

$$\frac{\partial f}{\partial y} y_x = \frac{df}{dx} - \frac{\partial f}{\partial y_x} y_{xx} - \frac{\partial f}{\partial x}. \quad (3)$$

Now, multiplying (1) by y_x gives

$$y_x \frac{\partial f}{\partial y} - y_x \frac{d}{dx}\left(\frac{\partial f}{\partial y_x}\right) = 0. \quad (4)$$

Substituting (3) into (4) then gives

$$\frac{df}{dx} - \frac{\partial f}{\partial y_x} y_{xx} - \frac{\partial f}{\partial x} - y_x \frac{d}{dx}\left(\frac{\partial f}{\partial y_x}\right) = 0 \quad (5)$$

$$-\frac{\partial f}{\partial x} + \frac{d}{dx}\left(f - y_x \frac{\partial f}{\partial y_x}\right) = 0. \quad (6)$$

This form is especially useful if $f_x = 0$, since in that case

$$\frac{d}{dx}\left(f - y_x \frac{\partial f}{\partial y_x}\right) = 0, \quad (7)$$

which immediately gives

$$f - y_x \frac{\partial f}{\partial y_x} = C, \quad (8)$$

where C is a constant of integration (Weinstock 1974, pp. 24–5; Arfken 1985, pp. 928–29; Fox 1988, pp. 8–).

The Beltrami identity greatly simplifies the solution for the minimal AREA SURFACE OF REVOLUTION about a given axis between two specified points. It also allows straightforward solution of the BRACHISTOCHRONE PROBLEM.

See also BRACHISTOCHRONE PROBLEM, CALCULUS OF VARIATIONS, EULER-LAGRANGE DIFFERENTIAL EQUATION, SURFACE OF REVOLUTION

Bend (Curvature)

The bend of a circle C mutually tangent to three other circles is defined as the signed CURVATURE of C. If the contacts are all external, the signs of the bends of all

four circles are taken as POSITIVE, whereas if one circle surrounds the other three, the sign of this circle is taken as NEGATIVE (Coxeter 1969). Bends can also be defined for spheres.

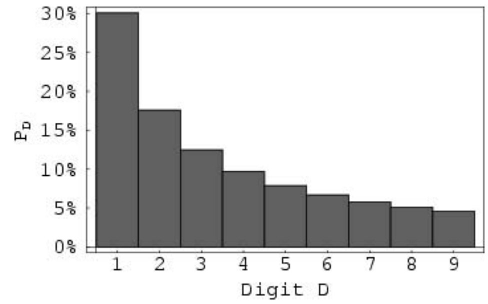
Benford's Law

A phenomenological law also called the first digit law, first digit phenomenon, or leading digit phenomenon. Benford's law states that in listings, tables of statistics, etc., the DIGIT 1 tends to occur with PROBABILITY ~30%, much greater than the expected 10% (i.e., one digit out of 10). Benford's law can be observed, for instance, by examining tables of LOGARITHMS and noting that the first pages are much more worn and smudged than later pages (Newcomb 1881). While Benford's law unquestionably applies to many situations in the real world, a satisfactory explanation has been given only recently through the work of Hill (1996).



Benford's law applies to data that are *not* dimensionless, so the numerical values of the data depend on the units. If there exists a universal probability distribution $P(x)$ over such numbers, then it must be invariant under a change of scale, so

$$P(kx) = f(k)P(x). \tag{1}$$

If $\int P(x)\,dx = 1$, then $\int P(kx)\,dx = 1/k$, and normalization implies $f(k) = 1/k$. Differentiating with respect to k and setting $k = 1$ gives

$$xP'(x) = -P(x), \tag{2}$$

having solution $P(x) = 1/x$. Although this is not a proper probability distribution (since it diverges), both the laws of physics and human convention impose cutoffs. For example, if street addresses are distributed uniformly over the range of 1 to some maximum cutoff value, then they'll obey something close to Benford's law.

If many powers of 10 lie between the cutoffs, then the probability that the first (decimal) digit is D is given by the LOGARITHMIC DISTRIBUTION

$$P_D = \frac{\int_D^{D+1} P(x)\,dx}{\int_1^{10} P(x)\,dx} = \frac{\ln\left(\frac{D+1}{D}\right)}{\ln 10} = \frac{\ln(D+1) - \ln(D)}{\ln 10} \tag{3}$$

for $D = 1, \ldots, 9$, illustrated above and tabulated below.

D	P_D	D	P_D
1	0.30103	6	0.0669468
2	0.176091	7	0.0579919
3	0.124939	8	0.0511525
4	0.09691	9	0.0457575
5	0.0791812		

However, Benford's law applies not only to scale-invariant data, but also to numbers chosen from a variety of different sources. Explaining this fact requires a more rigorous investigation of CENTRAL LIMIT-like theorems for the MANTISSAS of random variables under MULTIPLICATION. As the number of variables increases, the density function approaches that of a LOGARITHMIC DISTRIBUTION. Hill (1996) rigorously demonstrated that the "distribution of distributions" given by random samples taken from a variety of different distributions is, in fact, Benford's law (Matthews 1999).

One striking example of Benford's law is given by the 54 million real constants in Plouffe's "Inverse Symbolic Calculator" database, 30% of which begin with the DIGIT 1. Taking data from several disparate sources, the table below, shows the distribution of first digits as compiles by Benford (1938) in his original paper.

		First Digit									
Col.	Title	1	2	3	4	5	6	7	8	9	Samples

Bennequin's Conjecture

A BRAID with M strands and R components with P positive crossings and N negative crossings satisfies

$$|P - N| \le 2U + M - R \le P + N,$$

where U is the UNKNOTTING NUMBER. While the second part of the INEQUALITY was already known to be true (Boileau and Weber, 1983, 1984) at the time the conjecture was proposed, the proof of the entire conjecture was completed using results of Kronheimer and Mrowka on MILNOR'S CONJECTURE (and, independently, using MENASCO'S THEOREM).

Benson's Formula

An equation for a LATTICE SUM with $n = 3$

$$-b_3(1) = \sum_{i,\,j,\,k=-\infty}^{\infty}{}' \frac{(-1)^{i+j+k+1}}{\sqrt{i^2 + j^2 + k^2}}$$
$$= 12\pi \sum_{m,\,n=1,\,3,\,\ldots}^{\infty} \operatorname{sech}^2\left(\tfrac{1}{2}\pi\sqrt{m^2 + n^2}\right).$$

Here, the prime denotes that summation over (0, 0, 0) is excluded. The sum is numerically equal to $-1.74756\ldots$, a value known as "the" MADELUNG CONSTANT.

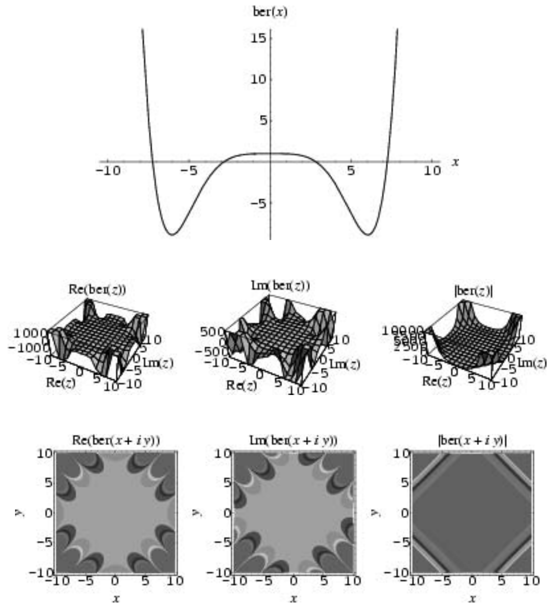
Ber



The REAL PART of

$$J_\nu(xe^{3\pi i/4}) = \operatorname{ber}_\nu(x) + i \operatorname{bei}_\nu(x). \tag{1}$$

The function $\operatorname{ber}_\nu(x)$ has the series expansion

$$\operatorname{ber}_\nu(x) = (\tfrac{1}{2}x)^\nu \sum_{k=0}^{\infty} \frac{\cos[(\frac{3}{4}\nu + \frac{1}{2}k)\pi]}{k!\Gamma(\nu + k + 1)} (\tfrac{1}{4}x^2)^k, \tag{2}$$

where $\Gamma(x)$ is the GAMMA FUNCTION (Abramowitz and Stegun 1972, p. 379).

The special case $\nu = 0$ gives

$$J_0\left(i\sqrt{i}\,x\right) \equiv \text{ber}(x) + i\,\text{bei}(x), \tag{3}$$

where $J_0(x)$ is the zeroth order BESSEL FUNCTION OF THE FIRST KIND. The function $\text{ber}_0(x) \equiv \text{ber}(x)$ has the series expansion

$$\text{ber}(x) \equiv \sum_{n=0}^{\infty} \frac{(-1)^n (\frac{1}{2}x)^{4n}}{[(2n)!]^2}. \tag{4}$$

Beraha Constants

The nth Beraha constant (or number) is given by

$$B(n) \equiv 2 + 2\cos\left(\frac{2\pi}{n}\right).$$

They appear to be ROOTS of the CHROMATIC POLYNOMIALS of planar triangular GRAPHS. $B(5)$ is $\phi + 1$, where ϕ is the GOLDEN RATIO, $B(7)$ is the SILVER CONSTANT, and $B(10) = \phi + 2$. The following table summarizes the first few Beraha numbers.

n	$B(n)$	Approx.
1	4	
2	0	
3	1	
4	2	
5	$\frac{1}{2}(3+\sqrt{5})$	2.618
6	3	
7	$2+2\cos(\frac{2}{7}\pi)$	3.247
8	$2+\sqrt{2}$	3.414
9	$2+2\cos(\frac{2}{9}\pi)$	3.532
10	$\frac{1}{2}(5+\sqrt{5})$	3.618

Bergman Space

Let G be an open subset of the COMPLEX PLANE $\mathbb{C}$, and let $L_a^2(G)$ denote the collection of all ANALYTIC FUNCTIONS $f: G \to C$ whose MODULUS is square integrable with respect to AREA measure. Then $L_a^2(G)$, sometimes also denoted $A^2(G)$, is called the Bergman space for G. Thus, the Bergman space consists of all the ANALYTIC FUNCTIONS in $L^2(G)$. The Bergman space can also be generalized to $L_a^p(G)$, where $0 < p < \infty$.

Bernays-Gödel Set Theory

VON NEUMANN-BERNAYS-GÖDEL SET THEORY

Bernoulli Differential Equation

$$\frac{dy}{dx} + p(x)y = q(x)y^n. \tag{1}$$

Let $v \equiv y^{1-n}$ for $n \neq 1$, then

$$\frac{dv}{dx} = (1-n)y^{-n}\frac{dy}{dx}. \tag{2}$$

Rewriting (1) gives

$$y^{-n}\frac{dy}{dx} = q(x) - p(x)y^{1-n} = q(x) - vp(x). \tag{3}$$

Plugging (3) into (2),

$$\frac{dv}{dx} = (1-n)[q(x) - vp(x)]. \tag{4}$$

Now, this is a linear FIRST-ORDER ORDINARY DIFFERENTIAL EQUATION OF THE FORM

$$\frac{dv}{dx} + vP(x) = Q(x), \tag{5}$$

where $P(x) \equiv (1-n)p(x)$ and $Q(x) \equiv (1-n)q(x)$. It can therefore be solved analytically using an INTEGRATING FACTOR

$$v = \frac{\int e^{\int P(x)\,dx} Q(x)\,dx + C}{e^{\int P(x)\,dx}} = \frac{(1-n)\int e^{(1-n)\int p(x)\,dx} q(x)\,dx + C}{e^{(1-n)\int p(x)\,dx}}, \tag{6}$$

where C is a constant of integration. If $n = 1$, then equation (1) becomes

$$\frac{dy}{dx} = y(q-p) \tag{7}$$

$$\frac{dy}{y} = (q-p)\,dx \tag{8}$$

$$y = C_2 e^{\int [q(x)-p(x)]\,dx}. \tag{9}$$

The general solution is then, with C_1 and C_2 constants,

$$y = \begin{cases} \left[\dfrac{(1-n)\int e^{(1-n)\int p(x)\,dx} q(x)\,dx + C_1}{e^{(1-n)\int p(x)\,dx}}\right]^{1/(1-n)} & \text{for } n \neq 1 \\ C_2 e^{\int [(q(x)-p(x)]\,dx} & \text{for } n = 1. \end{cases} \tag{10}$$

Bernoulli Distribution

A STATISTICAL DISTRIBUTION given by

$$P(n) = \begin{cases} q \equiv 1-p & \text{for } n = 0 \\ p & \text{for } n = 1 \end{cases} \tag{1}$$

$$= p^n(1-p)^{1-n} \quad \text{for } n = 0,\ 1. \tag{2}$$

The distribution of heads and tails in COIN TOSSING is a Bernoulli distribution with $p = q = 1/2$. The MOMENT-GENERATING FUNCTION of the Bernoulli distribution is

$$M(t) = \langle e^{tn} \rangle = \sum_{n=0}^{1} e^{tn} p^n (1-p)^{1-n} = e^0(1-p) + e^t p, \tag{3}$$

so

$$M(t) = (1-p) + pe^t \tag{4}$$

$$M'(t) = pe^t \tag{5}$$

$$M''(t) = pe^t \tag{6}$$

$$M^{(n)}(t) = pe^t, \tag{7}$$

and the MOMENTS about 0 are

$$\mu'_1 = \mu = M'(0) = p \tag{8}$$

$$\mu'_2 = M''(0) = p \tag{9}$$

$$\mu'_n = M^{(n)}(0) = p. \tag{10}$$

The MOMENTS about the MEAN are

$$\mu_2 = \mu'_2 - (\mu'_1)^2 = p - p^2 = p(1-p) \tag{11}$$

$$\mu_3 = \mu'_3 - 3\mu'_2\mu'_1 + 2(\mu'_1)^3 = p - 3p^2 + 2p^3 = p(1-p)(1-2p) \quad (12)$$

$$\mu_4 = \mu'_4 - 4\mu'_3\mu'_1 + 6\mu'_2(\mu'_1)^2 - 3(\mu'_1)^4 = p - 4p^2 + 6p^3 - 3p^4 = p(1-p)(3p^2-3p+1). \quad (13)$$

The MEAN, VARIANCE, SKEWNESS, and KURTOSIS are then

$$\mu = p \quad (14)$$

$$\sigma^2 = \mu_2 = p(1-p) \quad (15)$$

$$\gamma_1 = \frac{\mu_3}{\sigma_3} = \frac{p(1-p)(1-2p)}{[p(1-p)]^{3/2}} = \frac{1-2p}{\sqrt{p(1-p)}} \quad (16)$$

$$\gamma_2 = \frac{\mu_4}{\sigma_4} - 3 = \frac{p(1-2p)(2p^2-2p+1)}{p^2(1-p)^2} - 3 = \frac{6p^2-6p+1}{p(1-p)}. \quad (17)$$

To find an estimator $\hat{p}$ for the mean of a Bernoulli population with actual mean p, let N trials be made and suppose n successes are obtained. Assume an estimator given by

$$\hat{=} \frac{n}{N}, \quad (18)$$

so that the probability of obtaining the observed n successes in N trials is then

$$\binom{N}{n} p^n (1-p)^{N-n}. \quad (19)$$

The expectation value of the estimator $\hat{p}$ is therefore given by

$$\langle \hat{p} \rangle \cong \sum_{n=0}^{N} p \binom{N}{n} p^n (1-p)^{N-n} = (1-p)^N \left(\frac{1}{1-p}\right)^N p = p, \quad (20)$$

so $\langle p \rangle$ is indeed an UNBIASED ESTIMATOR for the population mean p.

Bernoulli Function

BERNOULLI POLYNOMIAL

Bernoulli Inequality

$$(1+x)^n > 1 + nx, \quad (1)$$

where $x > -1 \neq 0$ is a REAL NUMBER and $n > 1$ an INTEGER. This inequality can be proven by taking a MACLAURIN SERIES of $(1+x)^n$,

$$(1+x)^n = 1 + nx + \tfrac{1}{2}n(n-1)x^2 + \tfrac{1}{6}n(n-1)(n-2)x^3 + \cdots. \quad (2)$$

Since the series terminates after a finite number of terms for INTEGRAL n, the Bernoulli inequality for $x > 0$ is obtained by truncating after the first-order term.

When $-1 < x < 0$, slightly more finesse is needed. In this case, let $y = |x| = -x > 0$ so that $0 < y < 1$, and take

$$(1-y)^n = 1 - ny + \tfrac{1}{2}n(n-1)y^2 - \tfrac{1}{6}n(n-1)(n-2)y^3 + \cdots. \quad (3)$$

Since each POWER of y multiplies by a number < 1 and since the ABSOLUTE VALUE of the COEFFICIENT of each subsequent term is smaller than the last, it follows that the sum of the third order and subsequent terms is a POSITIVE number. Therefore,

$$(1-y)^n > 1 - ny, \quad (4)$$

or

$$(1+x)^n > 1 + nx, \quad \text{for } -1 < x < 0, \quad (5)$$

completing the proof of the INEQUALITY over all ranges of parameters.

For $x > -1 \neq 0$, the following generalizations of Bernoulli inequality are valid for real exponents:

$$(1+x)^a > 1 + ax \quad \text{if } a > 1 \text{ or } a < 0, \quad (6)$$

and

$$(1+x)^a < 1 + ax \quad \text{if } 0 < a < 1 \quad (7)$$

(Mitrinovic 1970).

Bernoulli Lemniscate

LEMNISCATE

Bernoulli Number

There are two definitions for the Bernoulli numbers. In modern usage, the Bernoulli numbers are written B_n, while the Bernoulli numbers encountered in older literature (where they are confusingly also denoted B_n) are distinguished by writing them as B_n^*. In each case, the Bernoulli numbers are a special case of the BERNOULLI POLYNOMIALS $B_n(x)$ or $B_n^*(x)$ with $B_n = B_n(0)$ and $B_n^* = B_n^*(0)$.

The older definition of the Bernoulli numbers, no longer in widespread use, defines B_n^* using the equations

$$\frac{x}{e^x-1}+\frac{x}{2}-1 \equiv \sum_{n=1}^{\infty} \frac{(-1)^{n-1} B_n^* x^{2n}}{(2n)!}$$
$$= \frac{B_1^* x^2}{2!} - \frac{B_2^* x^4}{4!} + \frac{B_3^* x^6}{6!} + \cdots \quad (1)$$

for $|x| < 2\pi$, or

$$1-\frac{x}{2}\cot\left(\frac{x}{2}\right) \equiv \sum_{n=1}^{\infty} \frac{B_n^* x^{2n}}{(2n)!}$$
$$= \frac{B_1^* x^2}{2!} - \frac{B_2^* x^4}{4!} + \frac{B_3^* x^6}{6!} + \cdots \quad (2)$$

for $|x| < \pi$ (Whittaker and Watson 1990, p. 125). Gradshteyn and Ryzhik (2000) denote these numbers B_n^*, while Bernoulli numbers defined by the newer (National Bureau of Standards) definition are denoted B_n. The B_n^* Bernoulli numbers may be calculated from the integral

$$B_n^* = 4n \int_0^{\infty} \frac{t^{2n-1}\, dt}{e^{2\pi t}-1}, \quad (3)$$

and analytically from

$$B_n^* = \frac{2(2n)!}{(2\pi)^{2n}} \sum_{p=1}^{\infty} p^{-2n} = \frac{2(2n)!}{(2\pi)^{2n}}\zeta(2n) \quad (4)$$

for $n = 1, 2, \ldots$, where $\zeta(z)$ is the RIEMANN ZETA FUNCTION.

The first few Bernoulli numbers b_n^* are

$$B_1^* = \tfrac{1}{6}$$
$$B_2^* = \tfrac{1}{30}$$
$$B_3^* = \tfrac{1}{42}$$
$$B_4^* = \tfrac{1}{30}$$
$$B_5^* = \tfrac{5}{66}$$
$$B_6^* = \tfrac{691}{2{,}730}$$
$$B_7^* = \tfrac{7}{6}$$
$$B_8^* = \tfrac{3{,}617}{510}$$
$$B_9^* = \tfrac{43{,}867}{798}$$
$$B_{10}^* = \tfrac{174{,}611}{330}$$
$$B_{11}^* = \tfrac{854{,}513}{138}.$$

Bernoulli numbers defined by the modern definition are denoted B_n and sometimes called "even-index" Bernoulli numbers. These are the Bernoulli numbers returned, by example, by the *Mathematica* function `BernoulliB[n]`. The first few are

$$B_0 = 1$$
$$B_1 = -\tfrac{1}{2}$$
$$B_2 = \tfrac{1}{6}$$
$$B_4 = -\tfrac{1}{30}$$
$$B_6 = \tfrac{1}{42}$$
$$B_8 = -\tfrac{1}{30}$$
$$B_{10} = \tfrac{5}{66}$$
$$B_{12} = -\tfrac{691}{2{,}730}$$
$$B_{14} = \tfrac{7}{6}$$
$$B_{16} = -\tfrac{3{,}617}{510}$$
$$B_{18} = \tfrac{43{,}867}{798}$$
$$B_{20} = -\tfrac{174{,}611}{330}$$
$$B_{22} = \tfrac{854{,}513}{138}$$

(Sloane's A000367 and A002445), with

$$B_{2n+1} = 0 \quad (5)$$

for $n = 1, 2, \ldots$ The Bernoulli numbers B_n are a superset of the archaic ones B_n^* since

$$B_n \equiv \begin{cases} 1 & \text{for } n=0 \\ -\frac{1}{2} & \text{for } n=1 \\ (-1)^{(n/2)-1} B_{n/2}^* & \text{for } n \text{ even} \\ 0 & \text{for } n \text{ odd.} \end{cases} \quad (6)$$

The B_n can be defined by the identity

$$\frac{x}{e^x-1} \equiv \sum_{n=0}^{\infty} \frac{B_n x^n}{n!}. \quad (7)$$

These relationships can be derived using the generating function

$$F(x, t) = \sum_{n=0}^{\infty} \frac{B_n(x) t^n}{n!}, \quad (8)$$

which converges uniformly for $|t| < 2\pi$ and all x (Castellanos 1988). Taking the partial derivative gives

$$\frac{\partial F(x, t)}{\partial x} = \sum_{n=0}^{\infty} \frac{B_{n-1}(x) t^n}{(n-1)!} = t \sum_{n=0}^{\infty} \frac{B_n(x) t^n}{n!} = tF(x, t). \quad (9)$$

The solution to this differential equation can be found

using SEPARATION OF VARIABLES as

$$F(x,\ t)=T(t)e^{xt}, \tag{10}$$

so integrating gives

$$\int_0^1 F(x,\ t)\,dx=T(t)\int_0^1 e^{xt}\,dx=T(t)\,\frac{e^t-1}{t}. \tag{11}$$

But integrating (11) explicitly gives

$$\int_0^1 F(x,\ t)\,dx=\sum_{n=0}^{\infty}\frac{t^n}{n!}\int_0^1 B_n(x)\,dx$$

$$=1+\sum_{n=0}^{\infty}\frac{t^n}{n!}\int_0^1 B_n(x)\,dx=1, \tag{12}$$

so

$$T(t)\,\frac{e^t-1}{t}=1. \tag{13}$$

Solving for $T(t)$ and plugging back into (10) then gives

$$\frac{te^{xt}}{e^t-1}=\sum_{n=0}^{\infty}\frac{B_n(x)t^n}{n!} \tag{14}$$

(Castellanos 1988). Setting $x=0$ and adding $t/2$ to both sides then gives

$$\tfrac{1}{2}t\coth(\tfrac{1}{2}t)=\sum_{n=0}^{\infty}\frac{B_{2n}t^{2n}}{(2n)!}. \tag{15}$$

Letting $t=2ix$ then gives

$$x\cot x=\sum_{n=0}^{\infty}(-1)^n B_{2n}\,\frac{(2x)^{2n}}{(2n)!} \tag{16}$$

for $x\in[-\pi,\ \pi]$. The Bernoulli numbers may also be calculated from the integral

$$B_n=\frac{n!}{2\pi i}\int\frac{z}{e^z-1}\frac{dz}{z^{n+1}}, \tag{17}$$

or from

$$B_n=\lim_{x\to 0}\frac{d^n}{dx^n}\frac{x}{e^x-1}. \tag{18}$$

The Bernoulli numbers satisfy the identity

$$\binom{k+1}{1}B_k+\binom{k+1}{2}B_{k-1}+\cdots+\binom{k+1}{k}B_1+B_0=0, \tag{19}$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT. They also satisfy the nice sum identity

$$\sum_{i=0}^{n}\frac{(1-2^{1-i})(1-2^{i-n+1})B_{n-i}B_i}{(n-i)!i!}=\frac{(1-n)B_n}{n!} \tag{20}$$

(Gosper).

An ASYMPTOTIC SERIES for the even Bernoulli numbers is

$$B_{2n}\sim(-1)^{n-1}4\sqrt{\pi n}\left(\frac{n}{\pi e}\right)^{2n}. \tag{21}$$

Bernoulli numbers appear in expressions OF THE FORM $\Sigma_{k=1}^{n} k^p$, where $p=1,\ 2,\ \ldots$ Bernoulli numbers also appear in the series expansions of functions involving $\tan x$, $\cot x$, $\csc x$, $\ln|\sin x|$, $\ln|\cos x|$, $\ln|\tan x|$, $\tanh x$, $\coth x$, and $\operatorname{csch} x$. An analytic solution exists for EVEN orders,

$$B_{2n}=\frac{(-1)^{n-1}2(2n)!}{(2\pi)^{2n}}\sum_{p=1}^{\infty}p^{-2n}=\frac{(-1)^{n-1}2(2n)!}{(2\pi)^{2n}}\,\zeta(2n) \tag{22}$$

for $n=1,\ 2,\ \ldots$, where $\zeta(2n)$ is the RIEMANN ZETA FUNCTION. Another intimate connection with the RIEMANN ZETA FUNCTION is provided by the identity

$$B_n=(-1)^{n+1}n\zeta(1-n). \tag{23}$$

The DENOMINATOR of B_{2k} is given by the VON STAUDT-CLAUSEN THEOREM

$$\operatorname{denom}(B_{2k})=\prod_{\substack{p\ \text{prime}\\(p-1)|2k}}^{2k+1}p, \tag{24}$$

which also implies that the DENOMINATOR of B_{2k} is SQUAREFREE (Hardy and Wright 1979). Another curious property is that the fraction part of B_n in DECIMAL has a DECIMAL PERIOD which divides n, and there is a single digit before that period (Conway 1996).

Bernoulli first used the Bernoulli numbers while computing $\Sigma_{k=1}^{n}k^p$. He used the property of the FIGURATE NUMBER TRIANGLE that

$$\sum_{i=0}^{n}a_{ij}=\frac{(n+1)a_{nj}}{j+1}, \tag{25}$$

along with a form for a_{nj} which he derived inductively to compute the sums up to $n=10$ (Boyer 1968, p. 85). For $p\in\mathbb{Z}>0$, the sum is given by

$$\sum_{k=1}^{n}k^p=\frac{(B+n+1)^{[p+1]}-B^{p+1}}{p+1}, \tag{26}$$

where the NOTATION $B^{[k]}$ means the quantity in question is raised to the appropriate POWER k, and all terms OF THE FORM B^m are replaced with the corresponding Bernoulli numbers B_m. Written explicitly in terms of a sum of POWERS,

$$\sum_{k=1}^{n}k^p=n^p+\sum_{k=0}^{p}\frac{B_k p!}{k!(p-k+1)!}\,n^{p-k+1}. \tag{27}$$

It is also true that the COEFFICIENTS of the terms in

such an expansion sum to 1 (which Bernoulli stated without proof). Ramanujan gave a number of curious infinite sum identities involving Bernoulli numbers (Berndt 1994).

G. J. Fee and S. Plouffe have computed $B_{200,000}$, which has $\sim 800,000$ DIGITS (Plouffe). Plouffe and collaborators have also calculated B_n for n up to 72,000.

Bernoulli Number of the Second Kind

A number defined by $b_n = b_n(0)$, where $b_n(x)$ is a BERNOULLI POLYNOMIAL OF THE SECOND KIND (Roman 1974, p. 294), also called Cauchy numbers of the first kind. The first few for $n = 0, 1, 2, \ldots$ are 1, 1/2, $-1/6$, 1/4, $-19/30$, 9/4, ... (Sloane's A006232 and A006233). They are given by

$$b_n = \int_0^1 (x)_n \, dx,$$

where $(x)_n$ is a FALLING FACTORIAL, and have EXPONENTIAL GENERATING FUNCTION

$$E(x) = \frac{x}{\ln(1+x)} = 1 + \frac{1!}{2} x - \frac{2!}{6} x^2 + \frac{3!}{4} x^3 + \cdots.$$

See also BERNOULLI NUMBER, BERNOULLI POLYNOMIAL OF THE SECOND KIND

Bernoulli Polynomial

There are two definitions of Bernoulli polynomials in use. The nth Bernoulli polynomial is denoted here by $B_n(x)$ (Abramowitz and Stegun 1972), and the archaic form of the Bernoulli polynomial by $B_n^*(x)$ (or sometimes $\phi_n(x)$). When evaluated at zero, these definitions correspond to the BERNOULLI NUMBERS,

$$B_n \equiv B_n(0) \tag{1}$$

$$B_n^* \equiv B_n^*(0). \tag{2}$$

The Bernoulli polynomials are an APPELL SEQUENCE with

$$g(t) = \frac{e^t - 1}{t} \tag{3}$$

(Roman 1984, p. 31), giving the GENERATING FUNCTION

$$\frac{te^{tx}}{e^t - 1} \equiv \sum_{n=0}^{\infty} B_n(x) \frac{t^n}{n!} \tag{4}$$

(Abramowitz and Stegun 1972, p. 804), first obtained by Euler (1738). The first few Bernoulli polynomials are

$$B_0(x) = 1$$

$$B_1(x) = x - \tfrac{1}{2}$$

$$B_2(x) = x^2 - x + \tfrac{1}{6}$$

$$B_3(x) = x^3 - \tfrac{3}{2}x^2 + \tfrac{1}{2}x$$

$$B_4(x) = x^4 - 2x^3 + x^2 - \tfrac{1}{30}$$

$$B_5(x) = x^5 - \tfrac{5}{2}x^4 + \tfrac{5}{3}x^3 - \tfrac{1}{6}x$$

$$B_6(x) = x^6 - 3x^5 + \tfrac{5}{2}x^4 - \tfrac{1}{2}x^2 + \tfrac{1}{42}.$$

Whittaker and Watson (1990, p. 126) define an older type of "Bernoulli polynomial" by writing

$$t\,\frac{e^{zt} - 1}{e^t - 1} = \sum_{n=1}^{\infty} \frac{\phi_n(z)t^n}{n!} \tag{5}$$

instead of (5). This gives the polynomials

$$\phi_n(x) = B_n(x) - B_n, \tag{6}$$

where B_n is a BERNOULLI NUMBER, the first few of which are

$$\phi_1(x) = x$$

$$\phi_2(x) = x^2 - x$$

$$\phi_3(x) = x^3 - \tfrac{3}{2}x^2 + \tfrac{1}{2}x$$

$$\phi_4(x) = x^4 - 2x^3 + x^2$$

$$\phi_5(x) = x^5 - \tfrac{5}{2}x^4 + \tfrac{5}{3}x^3 - \tfrac{1}{6}x.$$

The Bernoulli polynomials also satisfy

$$B_n(1) = (-1)^n B_n(0) \tag{7}$$

and

$$B_n(1 - x) = (-1)^n B_n(x) \tag{8}$$

(Lehmer 1988), as well as the relation

$$B_n(x+1) - B_n(x) = nx^{n-1} \tag{9}$$

(Whittaker and Watson 1990, p. 127).
Bernoulli (1713) defined the polynomials in terms of sums of the POWERS of consecutive integers,

$$\sum_{k=0}^{m-1} k^{n-1} = \frac{1}{n}[B_n(m) - B_n(0)]. \tag{10}$$

The Bernoulli polynomials satisfy the RECURRENCE RELATION

$$\frac{dB_n}{dx} = nB_{n-1}(x) \tag{11}$$

(Appell 1882), and obey the identity

$$B_n(x) = (B + x)^n, \tag{12}$$

where B^k is interpreted here as $B_k(x)$. Hurwitz gave the FOURIER SERIES

$$B_n(x) = -\frac{n!}{(2\pi i)^n} \sum_{k=-\infty}^{\infty}{}' \; k^{-n} e^{2\pi ikx}, \tag{13}$$

for $0 < x < 1$, where the prime in the summation indicates that the term $k = 0$ is omitted. Performing the sum gives

$$B_n(x) = -\frac{n!}{(2\pi i)^n} \left[(-1)^n \mathrm{Li}_n(e^{-2\pi ix}) + \mathrm{Li}_n(e^{2\pi ix})\right], \tag{14}$$

where $\mathrm{Li}_n(x)$ is the POLYLOGARITHM function. Raabe (1851) found

$$\frac{1}{m} \sum_{k=0}^{m-1} B_n\left(x + \frac{k}{m}\right) = m^{-n} B_n(mx). \tag{15}$$

A sum identity involving the Bernoulli polynomials is

$$\sum_{k=0}^{m} \binom{m}{k} B_k(\alpha) B_{m-k}(\beta) = -(m-1)B_m(\alpha+\beta) + m(\alpha+\beta-1)B_{m-1}(\alpha+\beta) \quad (16)$$

for m an INTEGER. A sum identity due to S. M. Ruiz is

$$\sum_{k=0}^{n} (-1)^{k+n} \binom{n}{k} B_n(k) = n!, \quad (17)$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT. The Bernoulli polynomials are also given by the formula

$$B_n(x) = B_n(0) + \sum_{k=1}^{n} \frac{n}{k} S(n-1, k-1)(x)_k, \quad (18)$$

where $S(n, m)$ is a STIRLING NUMBER OF THE SECOND KIND and $(x)_k$ is a FALLING FACTORIAL (Roman 1984, p. 94). A general identity is given by

$$(n)_m x^{n-m} = \sum_{k=m}^{n} \frac{(n)_k}{(k-m+1)!} B_{n-k}(x), \quad (19)$$

which simplifies to

$$nx^{n-1} = \sum_{k=1}^{n} \binom{n}{k} B_{n-k}(x) \quad (20)$$

(Roman 1984, p. 97). Gosper gave the identity

$$\sum_{j=0}^{i} \frac{[2(i-j)-1]3^{2f}(2^{(2f+1)+1})B_{2(i-j)}B_{2j+1}(\frac{1}{3})}{[2(i-j)]!(2j+1)!} = \frac{2 \cdot 3^{2(i-1)}(2^{2i-1}+1)B_{2i-1}(\frac{1}{3}) - (i-\frac{1}{2})B_{2i}}{(2i)!}. \quad (21)$$

Roman (1984, p. 93) defines a generalization $B_n^{(\alpha)}(x)$ of the Bernoulli numbers with an additional free parameter such that $B_n(x) = B_n^{(1)}(x)$.

Bernoulli Polynomial of the Second Kind

Polynomials $b_n(x)$ which form a SHEFFER SEQUENCE with

$$g(t) = \frac{t}{e^t - 1} \quad (1)$$

$$f(t) = e^t - 1, \quad (2)$$

giving GENERATING FUNCTION

$$\sum_{k=0}^{\infty} \frac{b_k(x)}{k!} t^k = \frac{t(t+1)^x}{\ln(1+t)}. \quad (3)$$

Roman (1984) defines BERNOULLI NUMBERS OF THE SECOND KIND as $b_n = b_n(0)$. They are related to the STIRLING NUMBERS OF THE FIRST KIND $s(n, m)$ by

$$b_n(x) = b_n(0) + \sum_{k=1}^{n} \frac{n}{k} s(n-1, k-1)x^k \quad (4)$$

(Roman 1984, p. 115), and obey the reflection formula

$$b_n(\tfrac{1}{2}n - 1 - x) = (-1)^n b_n(\tfrac{1}{2}n - 1 + x) \quad (5)$$

(Roman 1984, p. 119).

The first few Bernoulli polynomials of the second kind are

$$b_0(x) = 1$$
$$b_1(x) = \tfrac{1}{2}(2x+1)$$
$$b_2(x) = \tfrac{1}{6}(6x^2-1)$$
$$b_3(x) = \tfrac{1}{4}(4x^3-6x^2+1)$$
$$b_4(x) = \tfrac{1}{30}(30x^4-120x^3+120x^2-19).$$

Bernoulli's Method

In order to find a root of a polynomial equation

$$a_0x^n + a_1x^{n-1} + \cdots + a_n = 0, \tag{1}$$

consider the difference equation

$$a_0y(t+n) + a_1y(t+n-1) + \cdots + a_ny(t),$$

which is known to have solution

$$y(t) = w_1x_1^t + w_2x_2^t + \cdots + w_nx_n^t + \cdots, \tag{2}$$

where $w_1, w_2, \ldots$, are arbitrary functions of t with period 1, and $x_1, \ldots, x_n$ are roots of (1). In order to find the absolutely greatest root (1), take any arbitrary values for $y(0), y(1), \ldots, y(n-1)$. By repeated application of (2), calculate in succession the values $y(n), \ y(n+1), \ y(n+2), \ \ldots$ Then the ratio of two successive members of this sequence tends in general to a limit, which is the absolutely greatest root of (1).

Bernstein's Constant

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Let $E_n(f)$ be the error of the best uniform approximation to a REAL function $f(x)$ on the INTERVAL $[-1, 1]$ by REAL POLYNOMIALS of degree at most n. If

$$\alpha(x) = |x|, \tag{1}$$

then Bernstein showed that

$$0.267\ldots < \lim_{n\to\infty} 2nE_{2n}(\alpha) < 0.286. \tag{2}$$

He conjectured that the lower limit (β) was $\beta = 1/(2\times\sqrt{\pi})$. However, this was disproven by Varga and Carpenter (1987) and Varga (1990), who computed

$$\beta = 0.2801694990\ldots. \tag{3}$$

For rational approximations $p(x)/q(x)$ for p and q of degree m and n, D. J. Newman (1964) proved

$$\tfrac{1}{2}e^{-9\sqrt{n}} \leq E_{n,\,n}(\alpha) \leq 3e^{-\sqrt{n}} \tag{4}$$

for $n \geq 4$. Gonchar (1967) and Bulanov (1975) improved the lower bound to

$$e^{-\pi\sqrt{n+1}} \leq E_{n,\,n}(\alpha) \leq 3e^{-\sqrt{n}}. \tag{5}$$

Vjacheslavo (1975) proved the existence of POSITIVE constants m and M such that

$$m \leq e^{\pi\sqrt{n}}E_{n,\,n}(\alpha) < M \tag{6}$$

(Petrushev 1987, pp. 105–06). Varga *et al.* (1993) conjectured and Stahl (1993) proved that

$$\lim_{n\to\infty} e^{\pi\sqrt{2n}}E_{2n,\,2n}(\alpha) = 8. \tag{7}$$

Berry Conjecture

The longstanding conjecture that the nonimaginary solutions E_n of

$$\zeta(\tfrac{1}{2} + iE_n) = 0,$$

where $\zeta(z)$ is the RIEMANN ZETA FUNCTION, are the EIGENVALUES of an "appropriate" HERMITIAN OPERATOR H. Berry and Keating (1999) further conjecture that this operator is

$$H = xp = -i\left(x\frac{d}{dx} + \frac{1}{2}\right),$$

where x and p are the position and conjugate momentum operators, respectively.

See also RIEMANN HYPOTHESIS, RIEMANN ZETA FUNCTION

Berry Paradox

There are several versions of the Berry paradox, the original version of which was published by Bertrand Russell and attributed to Oxford University librarian Mr. G. Berry. In one form, the paradox notes that the number "one million, one hundred thousand, one hundred and twenty one" can be named by the description: "the first number not nameable in under ten words." However, this latter expression has only nine words, so the number *can* be named in under ten words, so there is an inconsistency in naming it in this manner!

Berry-Esséen Theorem

If $F(x)$ is a probability distribution with zero mean and

$$\rho = \int_{-\infty}^{\infty} |x|^3 \, dF(x) < \infty, \tag{1}$$

where the above integral is a STIELTJES INTEGRAL, then for all x and n,

$$|F_n(x) - \Phi(x) - \tfrac{1}{2}| < \frac{33}{4} \frac{\rho}{\sigma^3 \sqrt{n}}, \tag{2}$$

where $\Phi(x)$ is the NORMAL DISTRIBUTION FUNCTION, $\Phi(x) + 1/2 = \mathfrak{N}(x)$ in Feller's notation, and

$$F_n(x) = F^{n^*}(x\sigma\sqrt{n}) \tag{3}$$

is the normalized n-fold CONVOLUTION of $F(x)$ (Wallace 1958, Feller 1971).

Bertelsen's Number

An erroneous value of $\pi(10^9)$, where $\pi(x)$ is the PRIME COUNTING FUNCTION. Bertelsen's value of 50,847,478 is 56 lower than the correct value of 50,847,534.

See also PRIME COUNTING FUNCTION

Bertrand Curves

Two curves which, at any point, have a common principal NORMAL VECTOR are called Bertrand curves. The product of the TORSIONS of Bertrand curves is a constant.

Bertrand's Paradox

BERTRAND'S PROBLEM

Bertrand's Postulate

If $n > 3$, there is always at least one PRIME between n and $2n-2$. Equivalently, if $n > 1$, then there is always at least one PRIME between n and $2n$. The conjecture was first made by Bertrand in 1845 (Nagell 1951, p. 67). It was proved in 1850–1 by Chebyshev, and is therefore sometimes known as CHEBYSHEV'S THEOREM. An extension of this result is that if $n > k$, then there is a number containing a PRIME divisor $> k$ in the sequence $n, n+1, \ldots, n+k-1$. (The case $n = k+1$ then corresponds to Bertrand's postulate.) This was first proved by Sylvester, independently by Schur, and a simple proof was given by Erdos (Hoffman 1998, p. 37)

A related problem is to find the least value of θ so that there exists at least one PRIME between n and $n + \mathcal{O}(n^\theta)$ for sufficiently large n (Berndt 1994). The smallest known value is $\theta = 6/11 + \epsilon$ (Lou and Yao 1992).

Bertrand's Problem

What is the PROBABILITY that a CHORD drawn at random on a CIRCLE of RADIUS r (i.e., CIRCLE LINE PICKING) has length $\geq r$ (or sometimes greater than or equal to the side length of an inscribed equilateral triangle; Solomon 1978, p. 2)? The answer depends on the interpretation of "two points drawn at random," or more specifically on the "natural" measure for the problem.

In the most commonly considered measure, the ANGLES θ_1 and θ_2 are picked at random on the CIRCUMFERENCE of the circle. Without loss of generality, this can be formulated as the probability that the chord length of a single point at random angle θ measured from the x-AXIS on the unit circle. Since the length as a function of θ (CIRCLE LINE PICKING) is given by

$$s(\theta) = 2\left|\sin(\tfrac{1}{2}\theta)\right|, \qquad (1)$$

solving for $s(\theta) = 1$ gives $\pi/3$, so the fraction of the top unit semicircle having chord length greater than 1 is

$$P = \frac{\pi - \frac{\pi}{3}}{\pi} = \frac{2}{3}. \qquad (2)$$

However, if a point is instead placed at random on a RADIUS of the CIRCLE and a CHORD drawn PERPENDICULAR to it, then

$$P = \frac{\frac{\sqrt{3}}{2} r}{r} = \frac{\sqrt{3}}{2}. \qquad (3)$$

The latter interpretation is more satisfactory in the sense that the result remains the same for a rotated CIRCLE, a slightly smaller CIRCLE INSCRIBED in the first, or for a CIRCLE of the same size but with its center slightly offset. Jaynes (1983) shows that the interpretation of "random" as a continuous UNIFORM DISTRIBUTION over the RADIUS is the only one possessing all these three invariances.

Bertrand's Test

A CONVERGENCE TEST also called DE MORGAN'S AND BERTRAND'S TEST. If the ratio of terms of a SERIES $\{a_n\}_{n=1}^{\infty}$ can be written in the form

$$\frac{a_n}{a_{n+1}} = 1 + \frac{1}{n} + \frac{\rho_n}{n \ln n},$$

then the series converges if $\underline{\lim}_{n\to\infty} \rho_n > 1$ and diverges if $\overline{\lim}_{n\to\infty} \rho_n < 1$, where $\underline{\lim}_{n\to\infty}$ is the LOWER LIMIT and $\overline{\lim}_{n\to\infty}$ is the UPPER LIMIT.

Bertrand's Theorem

BERTRAND'S POSTULATE

Besov Space

A type of abstract SPACE which occurs in SPLINE and RATIONAL FUNCTION approximations. The Besov space $B^{\alpha}_{p,q}$ is a complete quasinormed space which is a BANACH SPACE when $1 \le p,\ q \le \infty$ (Petrushev and Popov 1987).

See also BANACH SPACE

Bessel Differential Equation

$$x^2 \frac{d^2y}{dx^2} + x \frac{dy}{dx} + (x^2 - m^2)y = 0. \tag{1}$$

Equivalently, dividing through by x^2,

$$\frac{d^2y}{dx^2} + \frac{1}{x}\frac{dy}{dx} + \left(1 - \frac{m^2}{x^2}\right)y = 0, \tag{2}$$

The solutions to this equation define the BESSEL FUNCTIONS. The equation has a regular SINGULARITY at 0 and an irregular SINGULARITY at ∞.

A transformed version of the Bessel differential equation given by Bowman (1958) is

$$x^2 \frac{d^2y}{dx^2} + (2p+1)x \frac{dy}{dx} + (\alpha^2 x^{2r} + \beta^2)y = 0. \tag{3}$$

The solution is

$$y = x^{-p}\left[C_1 J_{q/r}\left(\frac{\alpha}{r} x^r\right) + C_2 Y_{q/r}\left(\frac{\alpha}{r} x^r\right)\right], \tag{4}$$

where

$$q \equiv \sqrt{p^2 - \beta^2}, \tag{5}$$

$J_n(x)$ and $Y_n(x)$ are the BESSEL FUNCTIONS OF THE FIRST and SECOND KINDS, and C_1 and C_2 are constants. Another form is given by letting $y = x^{\alpha} J_n(\beta x^{\gamma})$, $\eta = yx^{-\alpha}$, and $\xi = \beta x^{\gamma}$ (Bowman 1958, p. 117), then

$$\frac{d^2y}{dx^2} - \frac{2\alpha - 1}{x}\frac{dy}{dx} + \left(\beta^2\gamma^2 x^{2\gamma-2} + \frac{\alpha^2 - n^2\gamma^2}{x^2}\right)y = 0. \tag{6}$$

The solution is

$$y = \begin{cases} x^{\alpha}[AJ_n(\beta x^{\gamma}) + BY_n(\beta x^{\gamma})] & \text{for integer } n \\ AJ_n(\beta x^{\gamma}) + BJ_{-n}(\beta x^{\gamma}) & \text{for noninteger } n. \end{cases} \tag{7}$$

Bessel Function

A function $Z_n(x)$ defined by the RECURRENCE RELATIONS

$$Z_{n+1} + Z_{n-1} \frac{2n}{x} Z_n$$

and

$$Z_{n+1} - Z_{n-1} = -2 \frac{dZ_n}{dx}.$$

The Bessel functions are more frequently defined as solutions to the DIFFERENTIAL EQUATION

$$x^2 \frac{d^2y}{dx^2} + x \frac{dy}{dx} + (x^2 - n^2)y = 0.$$

There are two classes of solution, called the BESSEL FUNCTION OF THE FIRST KIND $J_n(x)$ and BESSEL FUNCTION OF THE SECOND KIND $Y_n(x)$. (A BESSEL FUNCTION OF THE THIRD KIND is a special combination of the first and second kinds.) Several related functions are also defined by slightly modifying the defining equations.

Bessel Function Fourier Expansion

Let $n \geq 1/2$ and $\alpha_1, \alpha_2, \ldots$ be the POSITIVE ROOTS of $J_n(x) = 0$. An expansion of a function in the interval (0, 1) in terms of BESSEL FUNCTIONS OF THE FIRST KIND

$$f(x) = \sum_{l=1}^{\infty} A_r J_n(x\alpha_r), \tag{1}$$

has COEFFICIENTS found as follows:

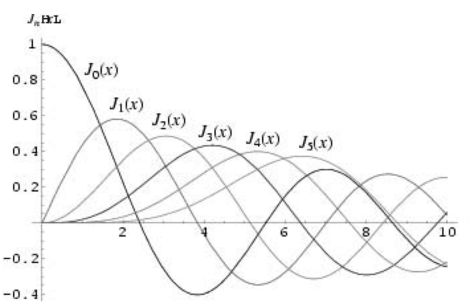
$$\int_0^1 xf(x)J_n(xa_l)\,dx = \sum_{r=1}^{\infty} A_r \int_0^1 xJ_n(x\alpha_r)J_n(x\alpha_l)\,dx. \tag{2}$$

But ORTHOGONALITY of BESSEL FUNCTION ROOTS gives

$$\int_0^1 xJ_n(x\alpha_l)J_n(x\alpha_r)\,dx = \tfrac{1}{2}\delta_{l,r}J_{n+1}^2(\alpha_r) \tag{3}$$

(Bowman 1958, p. 108), so

$$\int_0^1 xf(x)J_n(xa_l)\,dx = \tfrac{1}{2}\sum_{r=1}^{\infty} A_r\delta_{l,\,r}J_{n+1}^2(x\alpha_r)$$
$$= \tfrac{1}{2}A_l J_{n+1}^2(\alpha_l), \tag{4}$$



and the COEFFICIENTS are given by

$$A_l = \frac{2}{J_{n+1}^2(\alpha_l)} \int_0^1 xf(x)J_n(x\alpha_l)\,dx. \tag{5}$$

References

Bowman, F. *Introduction to Bessel Functions.* New York: Dover, 1958.

Bessel Function of the First Kind

The Bessel functions of the first kind $J_n(x)$ are defined as the solutions to the BESSEL DIFFERENTIAL EQUATION

$$x^2\frac{d^2y}{dx^2} + x\frac{dy}{dx} + (x^2 - m^2)y = 0 \tag{1}$$

which are nonsingular at the origin. They are sometimes also called CYLINDER FUNCTIONS or CYLINDRICAL HARMONICS. The above plot shows $J_n(x)$ for $n = 1, 2, \ldots, 5$.

To solve the differential equation, apply FROBENIUS METHOD using a series solution OF THE FORM

$$y = x^k \sum_{n=0}^{\infty} a_n x^n = \sum_{n=0}^{\infty} a_n x^{n+k}. \tag{2}$$

Plugging into (1) yields

$$x^2 \sum_{n=0}^{\infty} (k+n)(k+n-1)a_n x^{k+n-2}$$
$$+ x \sum_{n=0}^{\infty} (k+n)a_n x^{k+n-1}$$
$$+ x^2 \sum_{n=0}^{\infty} a_n x^{k+n} - m^2 \sum_{n=0}^{\infty} a_n x^{n+k} = 0 \tag{3}$$

$$\sum_{n=0}^{\infty} (k+n)(k+n-1)a_n x^{k+n} + \sum_{n=0}^{\infty} (k+n)a_n x^{k+n}$$

$$+\sum_{n=2}^{\infty} a_{n-2}x^{k+n} - m^2 \sum_{n=0}^{\infty} a_n x^{n+k} = 0. \tag{4}$$

The INDICIAL EQUATION, obtained by setting $n = 0$, is

$$a_0[k(k-1) + k - m^2] = a_0(k^2 - m^2) = 0. \tag{5}$$

Since a_0 is defined as the first NONZERO term, $k^2 - m^2 = 0$, so $k = \pm m$. Now, if $k = m$,

$$\sum_{n=0}^{\infty} [(m+n)(m+n-1) + (m+n) - m^2]$$

$$\times a_n x^{m+n} + \sum_{n=2}^{\infty} a_{n-2}x^{m+n} = 0 \tag{6}$$

$$\sum_{n=0}^{\infty} [(m+n)^2 - m^2]a_n x^{m+n} + \sum_{n=2}^{\infty} a_{n-2}x^{m+n} = 0 \tag{7}$$

$$\sum_{n=0}^{\infty} n(2m+n)a_n x^{m+n} + \sum_{n=2}^{\infty} a_{n-2}x^{m+n} = 0 \tag{8}$$

$$a_1(2m+1) + \sum_{n=2}^{\infty} [a_n n(2m+n) + a_{n-2}]x^{m+n} = 0. \tag{9}$$

First, look at the special case $m = -1/2$, then (9) becomes

$$\sum_{n=2}^{\infty} [a_n n(n-1) + a_{n-2}]x^{m+n} = 0, \tag{10}$$

so

$$a_n = -\frac{1}{n(n-1)}\, a_{n-2}. \tag{11}$$

Now let $n \equiv 2l$, where $l = 1, 2, \ldots$

$$a_{2l} = -\frac{1}{2l(2l-1)}\, a_{2l-2}$$

$$= \frac{(-1)^l}{[2l(2l-1)][2(l-1)(2l-3)]\cdots[2\cdot 1\cdot 1]}\, a_0$$

$$= \frac{(-1)^l}{2^l l!(2l-1)!!}\, a_0, \tag{12}$$

which, using the identity $2^l l!(2l-1)!! = (2l)!$, gives

$$a_{2l} = \frac{(-1)^l}{(2l)!}\, a_0. \tag{13}$$

Similarly, letting $n \equiv 2l + 1$,

$$a_{2l+1} = -\frac{1}{(2l+1)(2l)}\, a_{2l-1}$$

$$= \frac{(-1)^l}{[2l(2l+1)][2(l-1)(2l-1)]\cdots[2\cdot 1\cdot 3][1]}\, a_1, \tag{14}$$

which, using the identity $2^l l!(2l+1)!! = (2l+1)!$, gives

$$a_{2l+1} = \frac{(-1)^l}{2^l l!(2l+1)!!}\, a_1 = \frac{(-1)^l}{(2l+1)!}\, a_1. \tag{15}$$

Plugging back into (2) with $k = m = -1/2$ gives

$$y = x^{-1/2} \sum_{n=0}^{\infty} a_n x^n$$

$$= x^{-1/2}\left[\sum_{n=1,3,5,\ldots}^{\infty} a_n x^n + \sum_{n=0,2,4,\ldots}^{\infty} a_n x^n\right]$$

$$= x^{-1/2}\left[\sum_{l=0}^{\infty} a_{2l}x^{2l} + \sum_{l=0}^{\infty} a_{2l+1}x^{2l+1}\right]$$

$$= x^{-1/2}\left[a_0 \sum_{l=0}^{\infty} \frac{(-1)^l}{(2l)!}\, x^{2l} + a_1 \sum_{l=0}^{\infty} \frac{(-1)^l}{(2l+1)!}\, x^{2l+1}\right]$$

$$= x^{-1/2}(a_0 \cos x + a_1 \sin x). \tag{16}$$

The BESSEL FUNCTIONS of order $\pm 1/2$ are therefore defined as

$$J_{-1/2}(x) \equiv \sqrt{\frac{2}{\pi x}}\cos x \tag{17}$$

$$J_{1/2}(x) \equiv \sqrt{\frac{2}{\pi x}}\sin x, \tag{18}$$

so the general solution for $m = \pm 1/2$ is

$$y = a_0' J_{-1/2}(x) + a_1' J_{1/2}(x). \tag{19}$$

Now, consider a general $m \neq -1/2$. Equation (9) requires

$$a_1(2m+1) = 0 \tag{20}$$

$$[a_n n(2m+n) + a_{n-2}]x^{m+n} = 0 \tag{21}$$

for $n = 2, 3, \ldots$, so

$$a_1 = 0 \tag{22}$$

$$a_n = -\frac{1}{n(2m+n)}\, a_{n-2} \tag{23}$$

for $n = 2, 3, \ldots$ Let $n \equiv 2l + 1$, where $l = 1, 2, \ldots$, then

$$a_{2l+1} = -\frac{1}{(2l+1)[2(m+1)+1]}\, a_{2l-1} = \cdots$$

$$= \ldots = f(n, m)a_1 = 0, \tag{24}$$

where $f(n, m)$ is the function of l and m obtained by iterating the recursion relationship down to a_1. Now let $n \equiv 2l$, where $l = 1, 2, \ldots$, so

$$a_{2l} = -\frac{1}{2l(2m+2l)}\, a_{2l-2} = -\frac{1}{4l(m+l)}\, a_{2l-2}$$

$$= \frac{(-1)^l}{[4l(m+l)][4(l-1)(m+l-1)]\cdots[4\cdot(m+1)]}\, a_0. \tag{25}$$

Plugging back into (9),

$$y=\sum_{n=0}^{\infty} a_n x^{n+m} = \sum_{n=1,\,3,\,5,\,\ldots}^{\infty} a_n x^{n+m} + \sum_{n=0,\,2,\,4,\,\ldots}^{\infty} a_n x^{n+m}$$

$$=\sum_{l=0}^{\infty} a_{2l+1}x^{2l+m+1}+\sum_{l=0}^{\infty} a_{2l}x^{2l+m}$$

$$=a_0\sum_{l=0}^{\infty}\frac{(-1)^l}{[4l(m+l)][4(l-1)(m+l-1)]\cdots[4(m+1)]}x^{2l+m}$$

$$=a_0\sum_{l=0}^{\infty}\frac{[(-1)^l m(m-1)\cdots 1]x^{2l+m}}{[4l(m+l)][4(l-1)(m+l-1)]\cdots[4(m+1)m(m-1)\cdots 1]}$$

$$=a_0\sum_{l=0}^{\infty}\frac{(-1)^l m!}{2^{2l}l!(m+l)!}x^{2l+m}, \qquad (26)$$

Now define

$$J_m(x)\equiv\sum_{l=0}^{\infty}\frac{(-1)^l}{2^{2l+m}l!(m+l)!}x^{2l+m}, \qquad (27)$$

where the factorials can be generalized to GAMMA FUNCTIONS for nonintegral m. The above equation then becomes

$$y=a_0 2^m m! J_m(x)=a_0' J_m(x). \qquad (28)$$

Returning to equation (5) and examining the case $k=-m$,

$$a_1(1-2m)+\sum_{n=2}^{\infty}[a_n n(n-2m)+a_{n-2}]x^{n-m}=0. \qquad (29)$$

However, the sign of m is arbitrary, so the solutions must be the same for $+m$ and $-m$. We are therefore free to replace $-m$ with $-|m|$, so

$$a_1(1+2|m|)+\sum_{n=2}^{\infty}[a_n n(n+2|m|)+a_{n-2}]x^{|m|+n}=0, \qquad (30)$$

and we obtain the same solutions as before, but with m replaced by $|m|$.

$$J_m(x)=\begin{cases}\displaystyle\sum_{l=0}^{\infty}\frac{(-1)^l}{2^{2l+|m|}l!(|m|+l)l}x^{2l+|m|} & \text{for } |m|\neq-\tfrac{1}{2}\\ \sqrt{\dfrac{2}{\pi x}}\cos x & \text{for } m=-\tfrac{1}{2}\\ \sqrt{\dfrac{2}{\pi x}}\sin x & \text{for } m=\tfrac{1}{2}.\end{cases} \qquad (31)$$

We can relate J_m and J_{-m} (when m is an INTEGER) by writing

$$J_{-m}(x)=\sum_{l=0}^{\infty}\frac{(-1)^l}{2^{2l-m}l!(l-m)!}x^{2l-m}. \qquad (32)$$

Now let $l\equiv l'+m$. Then

$$J_{-m}(x)=\sum_{l'+m=0}^{\infty}\frac{(-1)^{l'+m}}{2^{2l'+m}(l'+m)!l!}x^{2l'+m}$$

$$=\sum_{l'=-m}^{-1}\frac{(-1)^{l'+m}}{2^{2l'+m}l'!(l'+m)!}x^{2l'+m}$$

$$+\sum_{l'=0}^{\infty}\frac{(-1)^{l'+m}}{2^{2l'+m}l'!(l'+m)!}x^{2'l+m}. \qquad (33)$$

But $l'!=\infty$ for $l'=-m,\ \ldots,\ -1$, so the DENOMINATOR is infinite and the terms on the right are zero. We therefore have

$$J_{-m}(x)=\sum_{l=0}^{\infty}\frac{(-1)^{l+m}}{2^{2l+m}l!(l+m)!}x^{2l+m}=(-1)^m J_m(x). \quad (34)$$

Note that the BESSEL DIFFERENTIAL EQUATION is second-order, so there must be two linearly independent solutions. We have found both only for $|m|$=1/2. For a general nonintegral order, the independent solutions are J_m and J_{-m}. When m is an INTEGER, the general (real) solution is OF THE FORM

$$Z_m\equiv C_1 J_m(x)+C_2 Y_m(x), \qquad (35)$$

where J_m is a Bessel function of the first kind, Y_m (a.k.a. N_m) is the BESSEL FUNCTION OF THE SECOND KIND (a.k.a. NEUMANN FUNCTION or WEBER FUNCTION), and C_1 and C_2 are constants. Complex solutions are given by the HANKEL FUNCTIONS (a.k.a. BESSEL FUNCTIONS OF THE THIRD KIND).

The Bessel functions are ORTHOGONAL in [0, 1] with respect to the weight factor x. Except when $2n$ is a NEGATIVE INTEGER,

$$J_m(z)=\frac{z^{-1/2}}{2^{2m+1/2}i^{m+1/2}\Gamma(m+1)}M_{0,\,m}(2iz), \qquad (36)$$

where $\Gamma(x)$ is the GAMMA FUNCTION and $M_{0,\,m}$ is a WHITTAKER FUNCTION. In terms of a CONFLUENT HYPERGEOMETRIC FUNCTION OF THE FIRST KIND, the Bessel function is written

$$J_\nu(z)=\frac{(\tfrac{1}{2}z)^\nu}{\Gamma(\nu+1)}\,{}_0F_1(\nu+1;\ -\tfrac{1}{4}z^2). \qquad (37)$$

A derivative identity for expressing higher order Bessel functions in terms of $J_0(x)$ is

$$J_n(x)=i^n T_n\left(i\frac{d}{dx}\right)J_0(x), \qquad (38)$$

where $T_n(x)$ is a CHEBYSHEV POLYNOMIAL OF THE FIRST KIND. Asymptotic forms for the Bessel functions are

$$J_m(x)\approx\frac{1}{\Gamma(m+1)}\left(\frac{x}{2}\right)^m \qquad (39)$$

for $x \ll 1$ and

$$J_m(x) \approx \sqrt{\frac{2}{\pi x}} \cos\left(x - \frac{m\pi}{2} - \frac{\pi}{4}\right) \quad (40)$$

for $x \gg 1$.

A derivative identity is

$$\frac{d}{dx}[x^m J_m(x)] = x^m J_{m-1}(x). \quad (41)$$

An integral identity is

$$\int_0^u u' J_0(u')\, du' = uJ_1(u). \quad (42)$$

Some sum identities are

$$1 = [J_0(x)]^2 + 2\sum_{k=1}^{\infty} [J_k(x)]^2 \quad (43)$$

(Abramowitz and Stegun 1972, p. 363),

$$1 = J_0(x) + 2\sum_{k=1}^{\infty} J_{2k}(x) \quad (44)$$

(Abramowitz and Stegun 1972, p. 361),

$$0 = \sum_{k=0}^{2n} (-1)^k J_k(z) J_{2n-k}(z) + 2\sum_{k=1}^{\infty} J_k(z) J_{2n+k}(z) \quad (45)$$

for $n \geq 1$ (Abramowitz and Stegun 1972, p. 361),

$$J_n(2z) = \sum_{k=0}^{n} J_k(z) J_{n-k}(z) + 2\sum_{k=1}^{\infty} (-1)^k J_k(z) J_{n+k}(z) \quad (46)$$

(Abramowitz and Stegun 1972, p. 361), and the JACOBI-ANGER EXPANSION

$$e^{iz\cos\theta} = \sum_{n=-\infty}^{\infty} i^n J_n(z) e^{in\theta}, \quad (47)$$

which can also be written

$$e^{iz\cos\theta} = J_0(z) + 2\sum_{n=1}^{\infty} i^n J_n(z)\cos(n\theta). \quad (48)$$

The Bessel function addition theorem states

$$J_n(y+z) = \sum_{m=-\infty}^{\infty} J_m(y) J_{n-m}(z). \quad (49)$$

The first k roots $x_1, \ldots, x_k$ of the Bessel function $J_n(x)$ can be found in *Mathematica* (Wolfram Research, Urbana, IL) using the command `BesselJZeros[n, k]` in the *Mathematica* add-on package `NumericalMath`BesselZeros`` (which can be loaded with the command `<<NumericalMath``). ROOTS of the FUNCTION $J_n(x)$ are given in the following table.

zero	$J_0(x)$	$J_1(x)$	$J_2(x)$	$J_3(x)$	$J_4(x)$	$J_5(x)$
1	2.4048	3.8317	5.1336	6.3802	7.5883	8.7715
2	5.5201	7.0156	8.4172	9.7610	11.0647	12.3386
3	8.6537	10.1735	11.6198	13.0152	14.3725	15.7002
4	11.7915	13.3237	14.7960	16.2235	17.6160	18.9801
5	14.9309	16.4706	17.9598	19.4094	20.8269	22.2178

The first k roots $x_1, \ldots, x_k$ of the derivative of the Bessel function $J_n'(x)$ can be found in *Mathematica* using the command `BesselJPrimeZeros[n, k]` in the *Mathematica* add-on package `NumericalMath`BesselZeros`` (which can be loaded with the command `<<NumericalMath``). The first few such ROOTS are given in the following table.

zero	$J_0'(x)$	$J_1'(x)$	$J_2'(x)$	$J_3'(x)$	$J_4'(x)$	$J_5'(x)$
1	3.8317	1.8412	3.0542	4.2012	5.3175	6.4156
2	7.0156	5.3314	6.7061	8.0152	9.2824	10.5199
3	10.1735	8.5363	9.9695	11.3459	12.6819	13.9872
4	13.3237	11.7060	13.1704	14.5858	15.9641	17.3128
5	16.4706	14.8636	16.3475	17.7887	19.1960	20.5755

Various integrals can be expressed in terms of Bessel functions

$$J_n(z) = \frac{1}{\pi}\int_0^{\pi} \cos(z\sin\theta - n\theta)\, d\theta, \quad (50)$$

which is BESSEL'S FIRST INTEGRAL,

$$J_n(z) = \frac{i^{-n}}{\pi}\int_0^{\pi} e^{iz\cos\theta}\cos(n\theta)\, d\theta \quad (51)$$

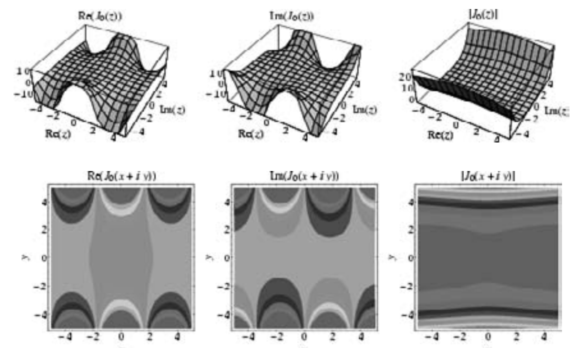
$$J_n(z) = \frac{1}{2\pi i^n}\int_0^{2\pi} e^{iz\cos\phi} e^{in\phi}\, d\phi \quad (52)$$

for $n = 1, 2, \ldots$,

$$J_n(z) = \frac{2}{\pi}\frac{x^n}{(2rn-1)!!}\int_0^{\pi/2} \sin^{2n} u\cos(x\cos u)\, du \quad (53)$$

for $n = 1, 2, \ldots$,

$$J_n(x) = \frac{1}{2\pi i}\int_{\gamma} e^{(x/2)(z-1/z)} z^{-n-1}\, dz \quad (54)$$



for $n > -1/2$. The Bessel functions are normalized so that

$$\int_0^{\infty} J_n(x)\, dx = 1 \quad (55)$$

for positive integral (and real) n. Integrals involving $J_1(x)$ include

$$\int_0^\infty \left[\frac{J_1(x)}{x}\right]^2 dx = \frac{4}{3\pi} \tag{56}$$

$$\int_0^\infty \left[\frac{J_1(x)}{x}\right]^2 x\, dx = \frac{1}{2}. \tag{57}$$

The special case of $n=0$ gives $J_0(z)$ as the series

$$J_0(z) = \sum_{k=0}^{\infty} (-1)^k \frac{(\frac{1}{4}z^2)^k}{(k!)^2} \tag{58}$$

(Abramowitz and Stegun 1972, p. 360), or the integral

$$J_0(z) = \frac{1}{\pi} \int_0^\pi e^{iz\cos\theta}\, d\theta. \tag{59}$$

Bessel Function of the Second Kind

A Bessel function of the second kind $Y_n(x)$ is a solution to the Bessel differential equation which is singular at the origin. Bessel functions of the second kind are also called Neumann functions or Weber functions. The above plot shows $Y_n(x)$ for $n = 1, 2, \ldots, 5$.

Let $v \equiv J_m(x)$ be the first solution and u be the other one (since the Bessel differential equation is second-order, there are two linearly independent solutions). Then

$$xu'' + u' + xu = 0 \tag{1}$$

$$xv'' + v' + xv = 0. \tag{2}$$

Take $v\times$ (1) minus $u\times$ (2),

$$x(u''v - uv'') + u'v - uv' = 0 \tag{3}$$

$$\frac{d}{dx}[x(u'v - uv')] = 0, \tag{4}$$

so $x(u'v - uv') = B$, where B is a constant. Divide by xv^2,

$$\frac{u'v - uv'}{v^2} = \frac{d}{dx}\left(\frac{u}{v}\right) = \frac{B}{xv^2} \tag{5}$$

$$\frac{u}{v} = A + B\int \frac{dx}{xv^2}. \tag{6}$$

Rearranging and using $v \equiv J_m(x)$ gives

$$\begin{aligned} u &= AJ_m(x) + BJ_m(x)\int \frac{dx}{xJ_m^2(x)} \\ &\equiv A'J_m(x) + B'Y_m(x), \end{aligned} \tag{7}$$

where Y_m is the so-called Bessel function of the second kind.

$Y_\nu(z)$ can be defined by

$$Y_\nu(z) = \frac{J_\nu(z)\cos(\nu\pi) - J_{-\nu}(z)}{\sin(\nu\pi)} \quad (8)$$

(Abramowitz and Stegun 1972, p. 358), where $J_\nu(z)$ is a Bessel function of the first kind and, for ν an integer n by the series

$$Y_n(z) = -\frac{(\frac{1}{2}z)^{-n}}{\pi}\sum_{k=0}^{n-1}\frac{(n-k-1)!}{k!}(\tfrac{1}{4}z^2)^k + \frac{2}{\pi}\ln(\tfrac{1}{2}z)J_n(z)$$

$$-\frac{(\frac{1}{2}z)^n}{\pi}\sum_{k=0}^{\infty}[\psi_0(k+1)+\psi_0(n+k+1)]\frac{(-\frac{1}{4}z^2)^k}{k!(n+k)!}, \quad (9)$$

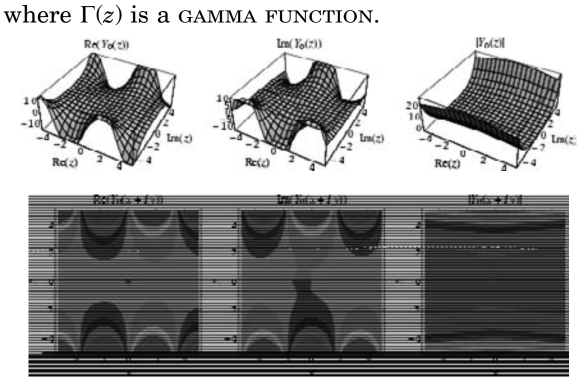
where $\psi_0(x)$ is the digamma function (Abramowitz and Stegun 1972, p. 360).

The function has the integral representations

$$Y_\nu(z) = \frac{1}{\pi}\ 1\nu t_0^\pi \sin(z\sin\theta - \nu\theta)\,d\theta$$

$$-\frac{1}{\pi}\ 1\nu t_0^\infty [e^{\nu t} + e^{-\nu t}(-1)^\nu]e^{-z\sinh t}\,dt. \quad (10)$$

$$= -\frac{2(\frac{1}{2}x)^{-\nu}}{\sqrt{\pi}\,\Gamma(\frac{1}{2}-\nu)}\int_1^\infty \frac{\cos(xt)\,dt}{(t^2-1)^{\nu+1/2}} \quad (11)$$



(Abramowitz and Stegun 1972, p. 360).

Asymptotic series are

$$Y_m(x) \sim \begin{cases} \frac{2}{\pi}[\ln(\frac{1}{2}x)+\gamma] & m=0,\ x \ll 1 \\ -\frac{\Gamma(m)}{\pi}\left(\frac{2}{x}\right)^m & m \neq 0,\ x \ll 1 \end{cases} \quad (12)$$

$$Y_m(x) \sim \sqrt{\frac{2}{\pi x}}\sin\left(x - \frac{m\pi}{2} - \frac{\pi}{4}\right) \quad x \gg 1, \quad (13)$$

where $\Gamma(z)$ is a gamma function.

For the special case $n=0$, $Y_0(x)$ is given by the series

$$Y_0(z) = \frac{2}{\pi}\left\{[\ln(\tfrac{1}{2}z)+\gamma]J_0(z) + \sum_{k=1}^{\infty}(-1)^{k+1}H_k\frac{(\frac{1}{4}z^2)^k}{(k!)^2}\right\}, \quad (14)$$

(Abramowitz and Stegun 1972, p. 360), where γ is the Euler-Mascheroni constant and H_n is a harmonic number.

Bessel Function of the Third Kind

Hankel Function

Bessel Polynomial

Krall and Find (1948) defined the Bessel polynomials as the function

$$y_n(x) = \sum_{k=0}^{n}\frac{(n+k!)}{(n-k)!k!}\left(\frac{x}{2}\right)^k \quad (1)$$

which satisfies the differential equation

$$x^2y'' + (2x+2)y' + n(n+1)y = 0. \quad (2)$$

Carlitz (1957) subsequently considered the related polynomials

$$p_n(x) = x^n y_{n-1}\left(\frac{1}{x}\right).$$

This polynomial forms an associated Sheffer sequence with

$$f(t) = t - \tfrac{1}{2}t^2. \quad (3)$$

This gives the generating function

$$\sum_{k=0}^{\infty}\frac{p_k(x)}{k!}t^k = e^{x(1-\sqrt{1-2t})}. \quad (4)$$

The explicit formula is

$$p_n(x) = \sum_{k=1}^{\infty}\frac{(2n-k-1)!}{2^{n-k}(k-1)!(n-k)!}x^k. \quad (5)$$

The polynomials satisfy the recurrence formula

$$p_n''(x) - 2p_n'(x) + 2np_{n-1}(x) = 0. \qquad (6)$$

The first few polynomials are

$$p_0(x) = 1$$
$$p_1(x) = x$$
$$p_2(x) = x^2 + x$$
$$p_3(x) = x^3 + 3x^2 + 3x$$
$$p_4(x) = x^4 + 6x^3 + 15x^2 + 15x.$$

Bessel's First Integral

$$J_n(x) = \frac{1}{\pi}\int_0^\pi \cos(n\theta - x\sin\theta)\,d\theta,$$

where $J_n(x)$ is a BESSEL FUNCTION OF THE FIRST KIND.

Bessel's Formula

BESSEL'S FINITE DIFFERENCE FORMULA, BESSEL'S INTERPOLATION FORMULA, BESSEL'S STATISTICAL FORMULA

Bessel's Inequality

If $f(x)$ is PIECEWISE CONTINUOUS and has a general FOURIER SERIES

$$\sum_i a_i \phi_i(x) \qquad (1)$$

with WEIGHTING FUNCTION $w(x)$, it must be true that

$$\int \left[f(x) - \sum_i a_i \phi_i(x)\right]^2 w(x)\,dx \geq 0 \qquad (2)$$

$$\int f^2(x) w(x)\,dx - 2\sum_i a_i \int f(x)\phi_i(x) w(x)\,dx$$

$$+\sum_i a_i^2 f\phi_i^2(x)w(x)\,dx \geq 0. \quad (3)$$

But the COEFFICIENT of the generalized FOURIER SERIES is given by

$$a_m \equiv \int f(x)\phi_m(x)w(x)\,dx, \quad (4)$$

so

$$\int f^2(x)w(x)\,dx - 2\sum_i a_i^2 + \sum_i a_i^2 \geq 0 \quad (5)$$

$$\int f^2(x)w(x)\,dx \geq \sum_i a_i^2. \quad (6)$$

Equation (6) is an inequality if the functions ϕ_i are not COMPLETE. If they are COMPLETE, then the inequality (2) becomes an equality, so (6) becomes an equality and is known as PARSEVAL'S THEOREM. If $f(x)$ has a simple FOURIER SERIES expansion with COEFFICIENTS a_0, a_1, a_n , a_π and $b_1, \ldots, b_n$, then

$$\tfrac{1}{2}a_0^2 + \sum_{k=1}^{\infty}(a_k^2 + b_k^2) \leq \frac{1}{\pi}\int_{-\pi}^{\pi}[f(x)]^2\,dx. \quad (7)$$

The inequality can also be derived from SCHWARZ'S INEQUALITY

$$|\langle f|g\rangle|^2 \leq \langle f|f\rangle\langle g|g\rangle \quad (8)$$

by expanding g in a superposition of EIGENFUNCTIONS of f, $g = \Sigma_i\, a_i f_i$. Then

$$\langle f|g\rangle = \sum_i a_i\langle f|f_i\rangle \leq \sum_i a_i \quad (9)$$

$$|\langle f|g\rangle|^2 \leq \left|\sum_i a_i\right|^2 = \left(\sum_i a_i\right)\left(\sum_i \bar{a}_i\right) = \sum_i a_i\bar{a}_i \leq \langle f|f\rangle\langle g|g\rangle, \quad (10)$$

where $\bar{f}$ is the COMPLEX CONJUGATE. If g is normalized, then $\langle g|g\rangle = 1$ and

$$\langle f|f\rangle \geq \sum_i a_i\bar{a}_i \quad (11)$$

BESSEL FUNCTION OF THE SECOND KIND

Beta

A financial measure of a fund's sensitivity to market movements which measures the relationship between a fund's excess return over Treasury Bills and the excess return of a benchmark index (which, by definition, has $\beta = 1$). A fund with a beta of β has performed $r \equiv (\beta - 1) \times 100\%$ better (or $|r|$ worse if $r < 0$) than its benchmark index (after deducting the T-bill rate) in up markets and $|r|$ worse (or $|r|$ better if $r < 0$) in down markets.

See also ALPHA, BETA DISTRIBUTION, BETA FUNCTION, BETA INTEGRAL, SHARPE RATIO

Beta Distribution

A general type of STATISTICAL DISTRIBUTION which is related to the GAMMA DISTRIBUTION. Beta distributions have two free parameters, which are labeled according to one of two notational conventions. The usual definition calls these α and β, and the other uses $\beta' \equiv \beta - 1$ and $\alpha' \equiv \alpha - 1$ (Beyer 1987, p. 534). The above plots are for various values of (α, β). The domain is $[0, 1]$, and the probability function $P(x)$ and DISTRIBUTION FUNCTION $D(x)$ are given by

$$P(x) = \frac{(1-x)^{\beta-1}x^{\alpha-1}}{B(\alpha, \beta)} = \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha)\Gamma(\beta)}(1-x)^{\beta-1}x^{\alpha-1} \quad (1)$$

$$D(x) = I(x; a, b), \quad (2)$$

where $B(a, b)$ is the BETA FUNCTION, $I(x; a, b)$ is the REGULARIZED BETA FUNCTION, and $\alpha, \beta > 0$. The distribution is normalized since

$$\int_0^1 P(x)\,dx = \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha)\Gamma(\beta)} \int_0^1 x^{\alpha-1}(1-x)^{\beta-1}\,dx \quad (3)$$

$$= \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha)\Gamma(\beta)} B(\alpha, \beta) = 1. \quad (4)$$

The CHARACTERISTIC FUNCTION is

$$\phi(t) = \mathscr{F}\left\{\frac{x^{a-1}(1-x)^{b-1}}{\beta(a, b)}[\tfrac{1}{2}\operatorname{sgn}(1-x) + \operatorname{sgn} x]\right\}$$
$$= {}_1F_1(a, a+b, it), \quad (5)$$

where $\mathscr{F}[f]$ is a FOURIER TRANSFORM with parameters $a = b = 1$ and ${}_1F_1(a; b; z)$ is a CONFLUENT HYPERGEOMETRIC FUNCTION.

The MEAN is

$$\mu = \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha)\Gamma(\beta)} \int_0^1 x^{\alpha-1}(1-x)^{\beta-1}x\,dx$$
$$= \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha)\Gamma(\beta)} B(\alpha+1, \beta) = \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha)\Gamma(\beta)} \frac{\Gamma(\alpha+1)\Gamma(\beta)}{\Gamma(\alpha+\beta+1)}$$
$$= \frac{\alpha}{\alpha+\beta}. \quad (6)$$

The RAW MOMENTS are given by

$$\mu'_r = \int_0^1 P(x)(x-\mu)^r\,dx = \frac{\Gamma(\alpha+\beta)\Gamma(\alpha+r)}{\Gamma(\alpha+\beta+r)\Gamma(\alpha)} \quad (7)$$

(Papoulis 1984, p. 147), and the CENTRAL MOMENTS by

$$\mu_r = \left(-\frac{\alpha}{\alpha+\beta}\right)^r {}_2F_1\left(-r, \alpha; \alpha+\beta; \frac{\alpha+\beta}{\alpha}\right), \quad (8)$$

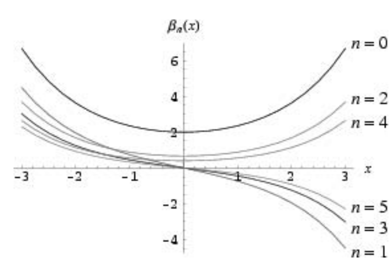
where $2F_1(a, b; c; x)$ is a HYPERGEOMETRIC FUNCTION. The VARIANCE, SKEWNESS, and KURTOSIS are therefore given by

$$\sigma^2 = \frac{\alpha\beta}{(\alpha+\beta)^2(\alpha+\beta+1)} \quad (9)$$

$$\gamma_1 = \frac{2(\beta-\alpha)\sqrt{1+\alpha+\beta}}{\sqrt{\alpha\beta}(2+\alpha+\beta)} \quad (10)$$

$$\gamma_2 = \frac{6[\alpha^3 + \alpha^2(1-2\beta) + \beta^2(1+\beta) - 2\alpha\beta(2+\beta)]}{\alpha\beta(\alpha+\beta+2)(\alpha+\beta+3)}. \quad (11)$$

The MODE of a variate distributed as $\beta(\alpha, \beta)$ is



$$\hat{x} = \frac{\alpha-1}{\alpha+\beta-2}. \quad (12)$$

Beta Exponential Function

Another "BETA FUNCTION" defined in terms of an integral is the "exponential" beta function, given by

$$\beta_n(z) \equiv \int_{-1}^1 t^n e^{-zt}\,dt \quad (1)$$

$$= n!z^{-(n+1)}\left[e^z \sum_{k=0}^n \frac{(-1)^k z^k}{k!} - e^{-z} \sum_{k=0}^n \frac{z^k}{k!}\right]. \quad (2)$$

If n is an integer, then

$$\beta_n(z) = (-1)^{n+1}E_{-n}(-z) - E_{-n}(z), \tag{3}$$

where $E_n(z)$ is the E_N-FUNCTION. The exponential beta function satisfies the RECURRENCE RELATION

$$z\beta_n(z) = (-1)^n e^z - e^{-z} + n\beta_{n-1}(z). \tag{4}$$

The values for $n = 0$, 1, and 2 are

$$\beta_0(z) = \frac{2\sinh z}{z} \tag{5}$$

$$\beta_1(z) = \frac{2(\sinh z - z\cosh z)}{z^2}. \tag{6}$$

$$\beta_2(z) = \frac{2(2+z^2)\sinh z - 4z\cosh z}{z^3}. \tag{7}$$

See also ALPHA FUNCTION, E_N-FUNCTION

Beta Function

The beta function is the name used by Legendre and Whittaker and Watson (1990) for the BETA INTEGRAL (also called the Eulerian integral of the first kind). To derive the integral representation of the beta function, write the product of two FACTORIALS as

$$m!n! = \int_0^\infty e^{-u}u^m\,du \int_0^\infty e^{-v}v^n\,dv. \tag{1}$$

Now, let $u \equiv x^2$, $v \equiv y^2$, so

$$\begin{aligned} m!n! &= 4\int_0^\infty e^{-x^2}x^{2m+1}\,dx \int_0^\infty e^{-y^2}y^{2n+1}\,dy \\ &= 4\int_{-\infty}^\infty \int_{-\infty}^\infty e^{-(x^2+y^2)}x^{2m+1}y^{2n+1}\,dx\,dy. \end{aligned} \tag{2}$$

Transforming to POLAR COORDINATES with $x = r\cos\theta$, $y = r\sin\theta$

$$\begin{aligned} m!n! &= 4\int_0^{\pi/2}\int_0^\infty e^{-r^2}(r\cos\theta)^{2m+1}(r\sin\theta)^{2n+1}r\,dr\,d\theta \\ &= 4\int_0^\infty e^{-r^2}r^{2m+2n+3}\,dr \int_0^{\pi/2}\cos^{2m+1}\theta\sin^{2n+1}\theta\,d\theta \\ &= 2(m+n+1)!\int_0^{\pi/2}\cos^{2m+1}\theta\,\sin^{2n+1}\theta\,d\theta. \end{aligned} \tag{3}$$

The beta function is then defined by

$$\begin{aligned} B(m+1,\ n+1) &= B(n+1,\ m+1) \\ &\equiv 2\int_0^{\pi/2}\cos^{2m+1}\theta\,\sin^{2n+1}\theta\,d\theta = \frac{m!n!}{(m+n+1)!}. \end{aligned} \tag{4}$$

Rewriting the arguments,

$$B(p,\ q) = \frac{\Gamma(p)\Gamma(q)}{\Gamma(p+q)} = \frac{(p-1)!(q-1)!}{(p+q-1)!}. \tag{5}$$

The general trigonometric form is

$$\int_0^{\pi/2}\sin^n x\cos^m x\,dx = \tfrac{1}{2}B(\tfrac{1}{2}(n+1),\ \tfrac{1}{2}(m+1)). \tag{6}$$

Equation (6) can be transformed to an integral over POLYNOMIALS by letting $u \equiv \cos^2\theta$,

$$B(m+1,\ n+1) \equiv \frac{m!n!}{(m+n+1)!} = \int_0^1 u^m(1-u)^n\,du \tag{7}$$

$$B(m,\ n) \equiv \frac{\Gamma(m)\Gamma(n)}{\Gamma(m+n)} = \int_0^1 u^{m-1}(1-u)^{n-1}\,du. \tag{8}$$

The beta function is implemented in *Mathematica* as `Beta[a, b]`.

For any z_1, z_2 with $\Re[z_1]$, $\Re[z_2] > 0$,

$$B(z_1,\ z_2) = B(z_2,\ z_1) \tag{9}$$

(Krantz 1999, p. 158).

The INCOMPLETE BETA FUNCTION $B(z;\ a,\ b)$, implemented in *Mathematica* as `Beta[z, a, b]`, is defined by the integral in (8) with an upper limit of z instead of 1. The REGULARIZED BETA FUNCTION $I(z;\ a,\ b)$, implemented in *Mathematica* as `BetaRegularized[z, a, b]` is defined by

$$I(z;\ a,\ b) = \frac{B(z;\ a,\ b)}{B(a,\ b)}. \tag{10}$$

To put it in a form which can be used to derive the LEGENDRE DUPLICATION FORMULA, let $x \equiv \sqrt{u}$, so $u = x^2$ and $du = 2x\,dx$, and

$$\begin{aligned} B(m,\ n) &= \int_0^1 x^{2(m-1)}(1-x^2)^{n-1}(2x\,dx) \\ &= 2\int_0^1 x^{2m-1}(1-x^2)^{n-1}\,dx. \end{aligned} \tag{11}$$

To put it in a form which can be used to develop integral representations of the BESSEL FUNCTIONS and HYPERGEOMETRIC FUNCTION, let $u \equiv x/(1+x)$, so

$$B(m+1,\ n+1) = \int_0^\infty \frac{u^m\,du}{(1+u)^{m+n+2}}. \tag{12}$$

Derivatives of the beta function are given by

$$\frac{d}{da}B(a,\ b) = B(a,\ b)[\psi_0(a) - \psi_0(a+b)] \tag{13}$$

$$\frac{d}{db}B(a,\ b) = B(a,\ b)[\psi_0(b) - \psi_0(a+b)] \tag{14}$$

$$\frac{d^2}{da^2}B(a,\ b) = B(a,\ b)$$

$$\times\left\{[\psi_0(a)-\psi_0(a+b)]^2+\psi_1(a)-\psi_1(a+b)\right\}, \quad (15)$$

$$\frac{d^2}{db^2}B(a, b)=B(a, b)$$
$$\times\left\{[\psi_0(b)-\psi_0(a+b)]^2+\psi_1(b)-\psi_1(a+b)\right\}, \quad (16)$$

$$\frac{d^2}{da\,db}B(a, b)$$
$$=B(a, b)\{[\psi_0(a)-\psi_0(a+b)][\psi_0(b)-\psi_0(a+b)]$$
$$-\psi_1(a+b) \quad (17)$$

where $\psi_n(x)$ is the POLYGAMMA FUNCTION.

Various identities can be derived using the GAUSS MULTIPLICATION FORMULA

$$B(np, nq)=\frac{\Gamma(np)\Gamma(nq)}{\Gamma[n(p+q)]}$$
$$=n^{-nq}\,\frac{B(p, q)B\left(p+\frac{1}{n}, q\right)\cdots B\left(p+\frac{n-1}{n}, q\right)}{B(q, q)B(2q, q)\cdots B([n-1]q, q)}. \quad (18)$$

Additional identities include

$$B(p, q+1)=\frac{\Gamma(p)\Gamma(q+1)}{\Gamma(p+q+1)}=\frac{q}{p}\,\frac{\Gamma(p+1)\Gamma(q)}{\Gamma([p+1]q)}$$
$$=\frac{q}{p}B(p+1, q) \quad (19)$$

$$B(p, q)=B(p+1, q)+B(p, q+1) \quad (20)$$

$$B(p, q+1)=\frac{q}{p+q}B(p, q). \quad (21)$$

If n is a POSITIVE INTEGER, then

$$B(p, n+1)=\frac{1\cdot 2\cdots n}{p(p+1)\cdots(p+n)} \quad (22)$$

$$B(p, p)B(p+\tfrac{1}{2}, p+\tfrac{1}{2})=\frac{\pi}{2^{4p-1}p} \quad (23)$$

$$B(p+q)B(p+q, r)=B(q, r)B(q+r, p). \quad (24)$$

Gosper gives the general formulas

$$\prod_{i=0}^{2n} B\left(\frac{i}{2n+1}+a, \frac{i}{2n+1}+b\right)$$
$$=\frac{(2n+1)^{(2n+1)/2}\pi^n B(n, \frac{1}{2}[(b+a)(2n+1)+1])B(a(2n+1), b(2n+1))}{(n-1)!} \quad (25)$$

for ODD n, and

$$\prod_{i=0}^{2n-1} B\left(\frac{i}{2n}+a, \frac{i}{2n}+b\right)$$
$$=\frac{n^n\pi^n B(n, 2(a+b)n)B(2an, 2bn)}{2^{2(a+b)n=n=1}(n-1)!B((a+b)n, (a+b+1)n)}, \quad (26)$$

which are an immediate consequence of the analogous identities for GAMMA FUNCTIONS. Plugging $n=1$ and $n=2$ into the above give the special cases

$$B(a, b)B(a+\tfrac{1}{3}, b+\tfrac{1}{3})B(a+\tfrac{2}{3}, b+\tfrac{2}{3})$$
$$=\frac{6\pi\sqrt{3}B(3a, 3b)}{1+3(a+b)} \quad (27)$$

$$B(a, b)B(a+\tfrac{1}{4}, b+\tfrac{1}{4})B(a+\tfrac{1}{2}, b+\tfrac{1}{2})B(a+\tfrac{3}{4}, b+\tfrac{3}{4})$$
$$=\frac{2^{3-4(a+b)}\pi^2 B(4a, 4b)}{(a+b)[1+4(a+b)]B(2(a+b), 2(a+b+1)}. \quad (28)$$

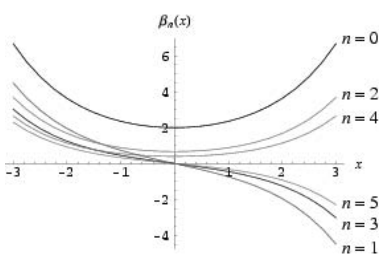
Beta Function (Exponential)

$$\mu_r = \left(-\frac{\alpha}{\alpha+\beta}\right)^r {}_2F_1\left(-r,\ \alpha;\ \alpha+\beta;\ \frac{\alpha+\beta}{\alpha}\right),$$

Another "BETA FUNCTION" defined in terms of an integral is the "exponential" beta function, given by

$$ {}_2F_1(a,\ b;\ c;\ x)\theta_2\ \frac{\alpha\beta}{(\alpha+\beta)^2(\alpha+\beta+1)} \quad (1)$$



$$= \frac{2(\beta-\alpha)\sqrt{1+\alpha+\beta}}{\sqrt{\alpha\beta}(2+\alpha+\beta)} \quad (2)$$

The exponential beta function satisfies the RECURRENCE RELATION

$$\frac{6[\alpha^3+\alpha^2(1-2\beta)+\beta^2(1+\beta)-2\alpha\beta(2+\beta)]}{\alpha\beta(\alpha+\beta+2)(\alpha+\beta+3)}. \quad (3)$$

The first few integral values are

$$\beta(\alpha,\ \beta) = \hat{x} = \frac{\alpha-1}{\alpha+\beta-2}. \quad (4)$$

$$= \beta_n(z) \quad (5)$$

$$\int_{-1}^{1} t^n e^{-zt}\, dt$$

$$= n!z^{-(n+1)}\left[e^z \sum_{k=0}^{n} \frac{(-1)^k z^k}{k!} - e^{-z} \sum_{k=0}^{n} \frac{z^k}{k!}\right]. \quad (6)$$

See also ALPHA FUNCTION

Beta Integral

The integral

$$\int_0^1 x^p(1-x)^q\, dx$$

called the EULERIAN INTEGRAL OF THE FIRST KIND by Legendre and Whittaker and Watson (1990). The solution is the BETA FUNCTION $B(p+1,\ q+1)$.

See also BETA FUNCTION, EULERIAN INTEGRAL OF THE FIRST KIND, EULERIAN INTEGRAL OF THE SECOND KIND

Whittaker, E. T. and Watson, G. N. *A Course in Modern Analysis, 4th ed.* Cambridge, England: Cambridge University Press, 1990.

Beta Prime Distribution

A distribution with probability function

$$P(x) = \frac{x^{\alpha-1}(1+x)^{-\alpha-\beta}}{B(\alpha,\ \beta)},$$

where B is a BETA FUNCTION. The MODE of a variate distributed as $\beta'(\alpha,\ \beta)$ is

$$\hat{x} = \frac{\alpha-1}{\beta+1}.$$

If x is a $\beta'(\alpha,\ \beta)$ variate, then $1/x$ is a $\beta'(\beta,\ \alpha)$ variate. If x is a $\beta(\alpha,\ \beta)$ variate, then $(1-x)/x$ and $x/(1-x)$ are $\beta'(\beta,\ \alpha)$ and $\beta'(\alpha,\ \beta)$ variates. If x and y are $\gamma(\alpha_1)$ and $\gamma(\alpha_2)$ variates, then x/y is a $\beta'(\alpha_1,\ \alpha_2)$ variate. If $x^2/2$ and $y^2/2$ are $\gamma(1/2)$ variates, then $z^2 \equiv (x/y)^2$ is a $\beta'(1/2,\ 1/2)$ variate.

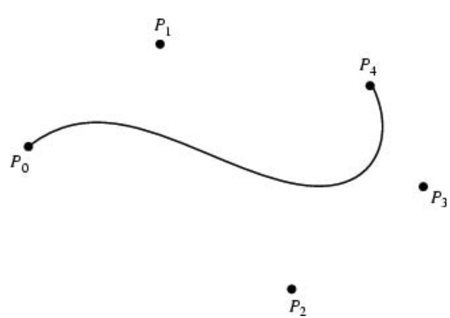
Betti Number

Betti numbers are topological objects which were proved to be invariants by Poincaré, and used by him to extend the POLYHEDRAL FORMULA to higher dimensional spaces. Informally, the Betti number is the maximum number of cuts that can be made without dividing a surface into two separate pieces (Gardner 1984, pp. 9–0). Formally, the nth Betti number is the rank of the nth HOMOLOGY GROUP of a TOPOLOGICAL SPACE. The following table gives the Betti number of some common surfaces.

SURFACE	Betti number
CROSS-CAP	1
CYLINDER	1
KLEIN BOTTLE	2
MÖBIUS STRIP	1
plane lamina	0
PROJECTIVE PLANE	1
SPHERE	0
TORUS	2



Let p_r be the RANK of the HOMOLOGY GROUP H_r of a TOPOLOGICAL SPACE K. For a closed, orientable surface of GENUS g, the Betti numbers are $p_0 = 1, p_1 = 2g$, and $p_2 = 1$. For a NONORIENTABLE SURFACE with k CROSS-CAPS, the Betti numbers are $p_0 = 1$, $p_1 = k - 1$, and $p_2 = 0$.

Bézier Curve

Given a set of $n+1$ control points $P_0, P_1, \ldots, P_n$, the corresponding Bézier curve (or Bernstein-Bézier curve) is given by

$$\mathbf{C}(t) = \sum_{i=0}^{n} \mathbf{P}_i B_{i,\,n}(t),$$

where $B_{i,\,n}(t)$ is a BERNSTEIN POLYNOMIAL and $t \in [0,\ 1]$.
A "rational" Bézier curve is defined by

$$\mathbf{C}(t) = \frac{\sum_{i=0}^{n} B_{i,\,p}(t) w_i \mathbf{P}_i}{\sum_{i=0}^{n} B_{i,\,p}(t) w_i},$$

where p is the order, $B_{i,\,p}$ are the BERNSTEIN POLYNOMIALS, $\mathbf{P}_i$ are control points, and the weight w_i of $\mathbf{P}_i$ is the last ordinate of the homogeneous point $\mathbf{P}_i^{\omega}$. These curves are CLOSED under perspective transformations, and can represent CONIC SECTIONS exactly.

The Bézier curve always passes through the first and last control points and lies within the CONVEX HULL of the control points. The curve is tangent to $\mathbf{P}_1 - \mathbf{P}_0$ and $\mathbf{P}_n - \mathbf{P}_{n-1}$ at the endpoints. The "variation diminishing property" of these curves is that no line can have more intersections with a Bézier curve than with the curve obtained by joining consecutive points with straight line segments. A desirable property of these curves is that the curve can be translated and rotated by performing these operations on the control points.

Undesirable properties of Bézier curves are their numerical instability for large numbers of control points, and the fact that moving a single control point changes the global shape of the curve. The former is sometimes avoided by smoothly patching together low-order Bézier curves. A generalization of the Bézier curve is the B-SPLINE.

Bézier Spline

BÉZIER CURVE, SPLINE

Bézout Numbers

Integers $(\lambda,\ \mu)$ for a and b such that

$$\lambda a + \mu b = \mathrm{GCD}(a,\ b).$$

For INTEGERS $a_1, \ldots, a_\pi$, the Bézout numbers are a set of numbers $k_1, \ldots, k_n$ such that

$$k_1 a_1 + k_2 a_2 + \cdots + k_n a_n = d,$$

where d is the GREATEST COMMON DIVISOR of $a_1, \ldots, a_\pi$.

See also GREATEST COMMON DIVISOR

Bézout's Theorem

In general, two algebraic curves of degrees m and n intersect in $m \cdot n$ points and cannot meet in more than $m \cdot n$ points unless they have a component in common (i.e., the equations defining them have a common factor). This can also be stated: if P and Q are two POLYNOMIALS with no roots in common, then there exist two other POLYNOMIALS A and B such that $AP + BQ = 1$. Similarly, given N POLYNOMIAL equations of degrees $n_1, n_2, \ldots, n_N$ in N variables, there are in general $n_1 n_2 \cdots n_N$ common solutions.

Séroul (2000, p. 10) uses the term Bézout's theorem for the following two theorems.

1. Let $a,\ b \in \mathbb{Z}$ be any two integers, then there exist $u,\ v \in \mathbb{Z}$ such that

$$au + bv = \mathrm{GCD}(a,\ b).$$

2. Two integers a and b are RELATIVELY PRIME if there exist $u,\ v \in \mathbb{Z}$ such that

$$au + bv = 1.$$

Bhargava's Theorem

Let the nth composition of a function $f(x)$ be denoted $f^{(n)}(x)$, such that $f^{(0)}(x) = f(x)$ and $f^{(1)}(x) = f(x)$. Denote the COMPOSITION of f and g by $f \circ g(x) = f(g(x))$, and define

$$\sum F(a,\ b,\ c) = F(a,\ b,\ c) + F(b,\ c,\ a) + F(c,\ b,\ a). \quad (1)$$

Let

$$\mathbf{u} \equiv (a,\ b,\ c) \quad (2)$$

$$\|\mathbf{u}\| \equiv a + b + c \quad (3)$$

$$\|\mathbf{u}\| \equiv a^4 + b^4 + c^4, \quad (4)$$

and

$$f(\mathbf{u}) = (a(b-c),\ b(c-a),\ c(a-b)) \quad (5)$$

$$g(\mathbf{u}) = \left(\sum a^2 b,\ \sum ab^2,\ 3abc\right). \quad (6)$$

Then if $|\mathbf{u}| = 0$ (i.e., $c = -a - b$),

$$\|f^{(m)} \circ g^{(n)}(\mathbf{u})\| = \|g^{(n)} \circ f^{(m)}(\mathbf{u})\| = 2(ab + bc + ca)^{2^{m+1}3^n}, \quad (7)$$

where $m,\ n \in \{0,\ 1,\ \ldots\}$ and COMPOSITION is done in terms of components.

Bianchi Identities

The RIEMANN TENSOR is defined by

$$R_{\lambda\mu\nu\kappa;\ \eta} = \frac{1}{2}\frac{\partial}{\partial x^\eta} \times \left(\frac{\partial^2 g_{\lambda\nu}}{\partial x^\kappa \partial x^\mu} - \frac{\partial^2 g_{\mu\nu}}{\partial x^\kappa \partial x^\lambda} - \frac{\partial^2 g_{\lambda\kappa}}{\partial x^\mu \partial x^\nu} + \frac{\partial^2 g_{\mu\kappa}}{\partial x^\nu \partial x^\lambda}\right). \quad (1)$$

Permuting ν, κ, and η (Weinberg 1972, pp. 146–47) gives the Bianchi identities

$$R_{\lambda\mu\nu\kappa;\ \eta} + R_{\lambda\mu\eta\nu;\ \kappa} + R_{\lambda\mu\kappa\eta;\ \nu} = 0, \quad (2)$$

which can be written concisely as

$$R^\alpha{}_{\beta[\lambda\mu;\ \nu]} = 0 \quad (3)$$

(Misner *et al.* 1973, p. 221), where $T_{[a_1 \ldots a_n]}$ denoted the ANTISYMMETRIC TENSOR part. Wald (1984, p. 39) calls

$$\nabla_{[a} R_{bc]d}{}^{\varepsilon} = 0 \quad (4)$$

the Bianchi identity, where ∇ is the COVARIANT DERIVATIVE, and $R_{abc}{}^{d'}$ is the RIEMANN TENSOR.

See also BIANCHI IDENTITIES (CONTRACTED), RIEMANN TENSOR

Bianchi Identities (Contracted)

CONTRACTING λ with ν in the BIANCHI IDENTITIES

$$R_{\lambda\mu\nu\kappa;\ \eta} + R_{\lambda\mu\eta\nu;\ \kappa} + R_{\lambda\mu\kappa\eta;\ \nu} = 0 \quad (1)$$

gives

$$R_{\mu\kappa;\,\eta} - R_{\mu\eta;\,\kappa} + R^{\nu}{}_{\mu\kappa\eta;\,\nu} = 0. \quad (2)$$

CONTRACTING again,

$$R_{;\,\eta} - R^{\mu}{}_{\eta;\,\mu} - R^{\nu}{}_{\eta;\,\nu} = 0, \quad (3)$$

or

$$(R^{\mu}{}_{\eta} - \tfrac{1}{2}\,\delta^{\mu}{}_{\eta} R)_{;\,\mu} = 0, \quad (4)$$

or

$$(R^{\mu\nu} - \tfrac{1}{2} g^{\mu\nu} R)_{;\,\mu} = 0. \quad (5)$$

Bias (Estimator)

The bias of an ESTIMATOR $\tilde{\theta}$ is defined as

$$B(\tilde{\theta}) \equiv \langle \tilde{\theta} \rangle - \theta.$$

It is therefore true that

$$\tilde{\theta} - \theta = (\tilde{\theta} - \langle \tilde{\theta} \rangle) + (\langle \tilde{\theta} \rangle - \theta) = (\tilde{\theta} - \langle \tilde{\theta} \rangle) + B(\tilde{\theta}).$$

An ESTIMATOR for which $B = 0$ is said to be UNBIASED ESTIMATOR.

See also BIASED ESTIMATOR, ESTIMATOR, UNBIASED ESTIMATOR

Bias (Series)

The bias of a SERIES is defined as

$$Q[a_i,\ a_{i+1},\ a_{i+2}] \equiv \frac{a_i a_{i+2} - a_{i+1}^2}{a_1 a_{i+1} a_{i+2}}.$$

A SERIES is GEOMETRIC IFF $Q = 0$. A SERIES is ARTISTIC IFF the bias is constant.

BIBD

BLOCK DESIGN

Bicentered Tree

A TREE (also called a bicentral tree) having two nodes that are GRAPH CENTERS. The numbers of bicentered trees on $n = 1, 2, \ldots$ nodes are 0, 1, 0, 1, 1, 3, 4, 11, 20, 51, 108 ... (Sloane's A000677).

See also CENTERED TREE, GRAPH CENTER, TREE

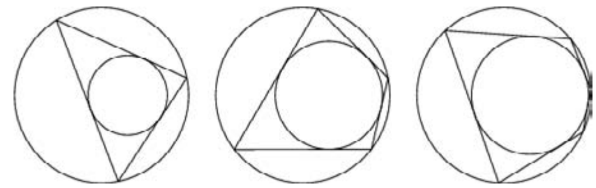
Bicentral Tree

BICENTERED TREE



Bicentric Perspective

Bicentric perspective is the study of the projection of 3D space from a pair of fiducial points instead of a single one, the latter of which may be called "centric" or "natural" PERSPECTIVE by way of distinction.

See also PERSPECTIVE, PROJECTION

References

Bensoussan and J.-P. Verjus). New York: Springer-Verlag, 233–51, 1992.

Bicentric Polygon

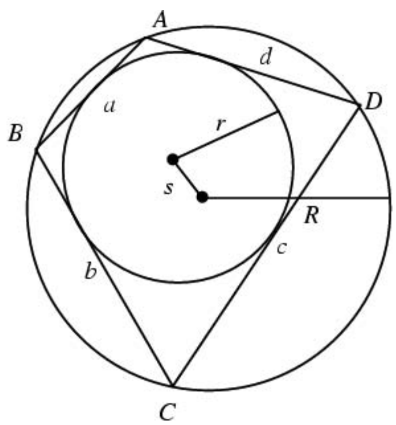
A POLYGON which has both a CIRCUMCIRCLE (which touches each vertex) and an INCIRCLE (which is tangent to each side). All TRIANGLES are bicentric with

$$R^2 - x^2 = 2Rr, \qquad (1)$$

where R is the CIRCUMRADIUS, r is the INRADIUS, and x is the separation of centers. For BICENTRIC QUADRILATERALS (Fuss's problem), the CIRCLES satisfy

$$2r^2(R^2 + x^2) = (R^2 - x^2)^2 \qquad (2)$$

(Dörrie 1965) or, in another form,



$$\frac{1}{(R-x)^2} + \frac{1}{(R+x)^2} = \frac{1}{r^2} \qquad (3)$$

(Davis; Durége; Casey 1888, pp. 109–10; Johnson 1929; Dörrie 1965).
If the circles permit successive tangents around the INCIRCLE which close the POLYGON for one starting point on the CIRCUMCIRCLE, then they do so for all points on the CIRCUMCIRCLE, a result known as PONCELET'S PORISM.

Bicentric Quadrilateral

A 4-sided BICENTRIC POLYGON, also called a CYCLIC-INSCRIPTABLE QUADRILATERAL. The INRADIUS r, CIRCUMRADIUS R, and offset s are connected by the equation

$$\frac{1}{(R-s)^2}+\frac{1}{(R+s)^2}=\frac{1}{r^2} \tag{1}$$

(Davis; Durége; Casey 1888, pp. 109–10; Johnson 1929; Dörie 1965; Coolidge 1971, p. 46). In addition

$$r=\frac{\sqrt{abcd}}{s} \tag{2}$$

$$R=\tfrac{1}{4}\sqrt{\frac{(ac+bd)(ad+bc)(ad+cd)}{abcd}} \tag{3}$$

(Beyer 1987), and

$$a+c=b+d. \tag{4}$$

The AREA of a bicentric quadrilateral is

$$A=\sqrt{abcd}. \tag{5}$$

Bicentric Triangle

All triangles are bicentric, i.e., possess both an INCIRCLE and a CIRCUMCIRCLE. This is not necessarily the case for polygons with four or more sides. The INRADIUS r and CIRCUMRADIUS R are connected by

$$\frac{1}{r+d}+\frac{1}{r-d}=\frac{1}{R},$$

where d is the distance between the INCENTER and CIRCUMCENTER (Coolidge 1971, p. 45).

Bichromatic Graph

A GRAPH with EDGES of two possible "colors," usually identified as red and blue. For a bichromatic graph with R red EDGES and B blue EDGES,

$$R+B\geq 2.$$

See also BLUE-EMPTY GRAPH, EXTREMAL COLORING, EXTREMAL GRAPH, MONOCHROMATIC FORCED TRIANGLE, RAMSEY NUMBER

Bicollared

A SUBSET $X\subset Y$ is said to be bicollared in Y if there exists an embedding $b: X\times[-1,\ 1]\to Y$ such that $b(x,\ 0)=x$ when $x\in X$. The MAP b or its image is then said to be the bicollar.

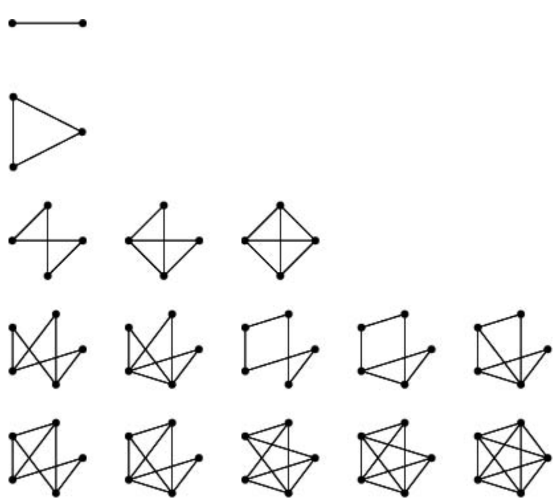
Bi-Connected Component



A maximal SUBGRAPH of an undirected graph such that any two edges in the SUBGRAPH lie on a common simple cycle.

See also STRONGLY CONNECTED COMPONENT

Biconnected Component

BLOCK

Biconnected Graph

A GRAPH with no ARTICULATION VERTICES is called biconnected (Skiena 1990, p. 175), block, or "nonseparable graph" (Harary 1994, p. 26). The numbers of biconnected simple graphs on $n = 1, 2, \ldots$ nodes are 0, 1, 1, 3, 10, 56, 468, ... (Sloane's A002218). A graph can be tested for biconnectivity using `BiconnectedQ`[*g*] in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).

Any graph containing a node of degree 1 cannot be biconnected. All HAMILTONIAN GRAPHS are biconnected (Skiena 1990, p. 177).

Bicorn

The bicorn is the name of a collection of QUARTIC CURVES studied by Sylvester in 1864 and Cayley in 1867 (MacTutor Archive). The bicorn is given by the PARAMETRIC EQUATIONS

$$x = a \sin t \tag{1}$$

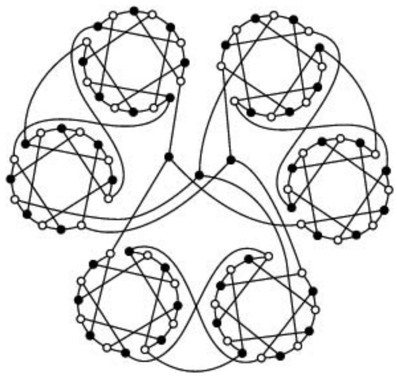
$$y = \frac{a \cos^2 t(2 + \cos t)}{3 + \sin^2 t} \tag{2}$$

and Cartesian equation

$$y^2(a^2 - x^2) = (x^2 + 2ay - a^2)^2 \tag{3}$$

(Mactutor, with the final a squared instead of to the first power). The graph of the bicorn is similar to that of the COCKED HAT CURVE.

The CURVATURE is given by



$$\kappa = \frac{6\sqrt{2}(\cos t - 2)^3(3 \cos t - 2) \sec t}{a[73 - 80 \cos t + 9 \cos(2t)]^{3/2}}. \tag{4}$$

Bicubic Graph

A BIPARTITE CUBIC GRAPH. Tutte (1971) conjectured that all 3-connected bicubic graphs are Hamiltonian (the TUTTE CONJECTURE). The Horton graph on 96 nodes provided the first counterexample (Bondy and Murty 1976, p. 240; illustrated above).

Horton subsequently found a counterexample on 92 nodes (Horton 1982). Two smaller (nonisomorphic) counterexamples on 78 nodes have since been found (Ellingham 1981, 1982b; Owens 1983). Ellingham and Horton (1983) subsequently found a nonhamiltonian 3-connected bicubic graph on 54 vertices, illustrated above.

Bicubic Spline

A bicubic spline is a special case of bicubic interpolation which uses an interpolation function OF THE FORM

$$y(x_1, x_2) = \sum_{i=1}^{4} \sum_{j=1}^{4} c_{ij} t^{i-1} u^{j-1}$$

$$y_{x_1}(x_1, x_2) = \sum_{i=1}^{4} \sum_{j=1}^{4} (i-1) c_{ij} t^{i-2} u^{j-1}$$

$$y_{x_2}(x_1, x_2) = \sum_{i=1}^{4} \sum_{j=1}^{4} (j-1) c_{ij} t^{i-1} u^{j-2}$$

$$y_{x_1 x_2} = \sum_{i=1}^{4} \sum_{j=1}^{4} (i-1)(j-1) c_{ij} t^{i-2} u^{j-2},$$

where c_{ij} are constants and u and t are parameters ranging from 0 to 1. For a bicubic spline, however, the partial derivatives at the grid points are determined globally by 1-D SPLINES.

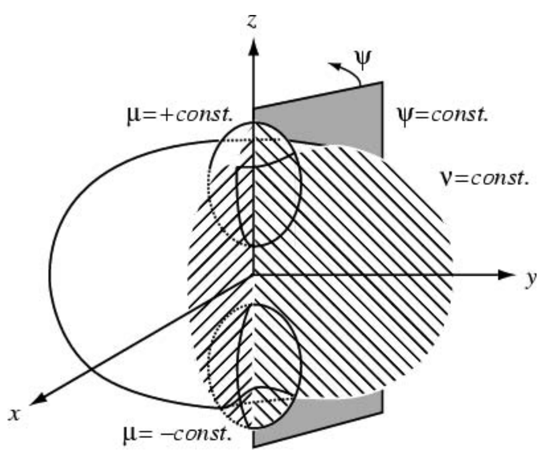
Bicupola

Two adjoined CUPOLAS.

See also CUPOLA, ELONGATED GYROBICUPOLA, ELONGATED ORTHOBICUPOLA, GYROBICUPOLA, ORTHOBICUPOLA

Bicuspid Curve



The PLANE CURVE given by the Cartesian equation

$$(x^2-a^2)(x-a)^2+(y^2-a^2)^2=0.$$

Bi-Cyclide Coordinates

BICYCLIDE COORDINATES

Bicyclide Coordinates

A coordinate system which is similar to BISPHERICAL COORDINATES but having fourth-degree surfaces instead of second-degree surfaces for constant μ. The coordinates are given by the transformation equations

$$x=\frac{a}{\Lambda}\operatorname{cn}\mu\operatorname{dn}\mu\operatorname{sn}\nu\operatorname{cn}\nu\cos\psi \tag{1}$$

$$y=\frac{a}{\Lambda}\operatorname{cn}\mu\operatorname{dn}\mu\operatorname{sn}\nu\operatorname{cn}\nu\sin\psi \tag{2}$$

$$z=\frac{a}{\Lambda}\sin\mu\operatorname{dn}\nu, \tag{3}$$

where

$$\Lambda\equiv 1-\operatorname{dn}^2\mu\operatorname{sn}^2\nu, \tag{4}$$

$\mu\in[0,K]$, $\nu\in[0,K']$, $\psi\in[0,2\pi)$, and $\operatorname{cn}x$, $\operatorname{dn}x$, and $\operatorname{sn}x$ are JACOBI ELLIPTIC FUNCTIONS. Surfaces of constant μ are given by the bicyclides

$$(x^2+y^2+z^2)^2+\frac{a^2}{k^4}\frac{(1-k^2)^2-2(1-k^2)\operatorname{dn}^2\mu+(1+k^2)\operatorname{dn}^4\mu}{\operatorname{dn}^2\mu\operatorname{cn}^2\mu}\times(x^2+y^2)-a^2\left(\operatorname{sn}^2\mu+\frac{1}{k^2\operatorname{sn}^2\mu}\right)z^2+\frac{a^4}{k^2}=0, \tag{5}$$

surfaces of constant ν by the cyclides of rotation

$$\left[\frac{\operatorname{cn}^2\nu}{a^2\operatorname{sn}^2\nu}(x^2+y^2)+\frac{\operatorname{dn}^2\nu}{a^2}z^2\right]^2-\frac{2\operatorname{cn}^2\nu}{a^2\operatorname{sn}^2\nu}(x^2+y^2)-\frac{2\operatorname{dn}^2\nu}{a^2}z^2+1=0, \tag{6}$$

and surfaces of constant ψ by the half-planes

$$\tan\psi=\frac{y}{x}. \tag{7}$$

See also BISPHERICAL COORDINATES, CAP-CYCLIDE COORDINATES, CYCLIDIC COORDINATES

Bicylinder

STEINMETZ SOLID

Bidiakis Cube

The 12-VERTEX graph consisting of a CUBE in which two opposite faces (say, top and bottom) have edges drawn across them which connect the centers of opposite sides of the faces in such a way that the orientation of the edges added on top and bottom are PERPENDICULAR to each other.

See also BISLIT CUBE, CUBE, CUBICAL GRAPH

Bieberbach Conjecture

The nth COEFFICIENT in the POWER SERIES of a UNIVALENT FUNCTION should be no greater than n. In other words, if

$$f(z) = a_0 + a_1 z + a_2 z^2 + \ldots + a_n z^n + \ldots$$

is a CONFORMAL MAP of a UNIT DISK on any domain, then $|a_n| \leq n|a_1|$. In more technical terms, "geometric extremality implies metric extremality." An alternate formulation is that $|a_j|leqj$ for any SCHLICHT FUNCTION f (Krantz 1999, p. 150).

The conjecture had been proven for the first six terms (the cases $n = 2$, 3, and 4 were done by Bieberbach, Lowner, and Garabedian and Schiffer, respectively), was known to be false for only a finite number of indices (Hayman 1954), and true for a convex or symmetric domain (Le Lionnais 1983). The general case was proved by Louis de Branges (1985). de Branges proved the MILIN CONJECTURE, which established the ROBERTSON CONJECTURE, which in turn established the Bieberbach conjecture (Stewart 1996).

author	result
Bieberbach (1916)	$\|a_2\| \leq 2$
Löwner (1923)	$\|a_3\| \leq 3$
Garabedian and Schiffer (1955)	$\|a_4\| \leq 4$
Pederson (1968), Ozawa (1969)	$\|a_6\| \leq 6$
Pederson and Schiffer (1972)	$\|a_5\| \leq 5$
de Branges (1985)	$\|a_j\|leqj$ for all j

The sum

$$\sum_{j=k}^{n} (-1)^{k+j} \binom{2j}{j-k} \binom{n+j+1}{n-j} e^{-jt}$$

was an essential tool in de Branges' proof (Koepf 1998, p. 29).

Bifolium

A FOLIUM with $b = 0$. The bifolium is the PEDAL CURVE of the DELTOID, where the PEDAL POINT is the MIDPOINT of one of the three curved sides. The Cartesian equation is

$$(x^2 + y^2)^2 = 4axy^2$$

and the POLAR equation is

$$r = 4a \sin^2 \theta \cos \theta.$$

Bifurcation

A period doubling, quadrupling, etc., that accompanies the onset of CHAOS. It represents the sudden appearance of a qualitatively different solution for a nonlinear system as some parameter is varied. Bifurcations come in four basic varieties: FLIP BIFURCATION, FOLD BIFURCATION, PITCHFORK BIFURCATION, and TRANSCRITICAL BIFURCATION (Rasband 1990).

Biharmonic Equation

The differential equation obtained by applying the BIHARMONIC OPERATOR and setting to zero.

$$\nabla^4 \phi = 0. \tag{1}$$

In CARTESIAN COORDINATES, the biharmonic equation is

$$\begin{aligned}\nabla^4 \phi &= \nabla^2(\nabla^2)\phi \\ &= \left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2}\right)\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2}\right)\phi \\ &= \frac{\partial^4 \phi}{\partial x^4} + \frac{\partial^4 \phi}{\partial y^4} + \frac{\partial^4 \phi}{\partial z^4} + 2\frac{\partial^4 \phi}{\partial x^2 \partial y^2} + 2\frac{\partial^4 \phi}{\partial y^2 \partial z^2} + 2\frac{\partial^4 \phi}{\partial x^2 \partial z^2} \\ &= 0. \end{aligned} \tag{2}$$

In POLAR COORDINATES (Kaplan 1984, p. 148)

$$\nabla^4\phi = \phi_{rrrr} + \frac{2}{r^2}\,\phi_{rr\theta\theta} + \frac{1}{r^4}\,\phi_{\theta\theta\theta\theta} + \frac{2}{r}\,\phi_{rrr} - \frac{2}{r^3}\,\phi_{r\theta\theta}$$
$$-\frac{1}{r^2}\,\phi_{rr} + \frac{4}{r^4}\,\phi_{\theta\theta} + \frac{1}{r^3}\,\phi_r = 0. \quad (3)$$

For a radial function $\phi(r)$, the biharmonic equation becomes

$$\nabla^4\phi = \frac{1}{r}\frac{d}{dr}\left\{r\frac{d}{dr}\left[\frac{1}{r}\frac{d}{dr}\left(r\frac{d\phi}{dr}\right)\right]\right\}$$
$$= \phi_{rrrr} + \frac{2}{r}\,\phi_{rrr} - \frac{1}{r^2}\,\phi_{rr} + \frac{1}{r^3}\,\phi_r = 0. \quad (4)$$

Writing the inhomogeneous equation as

$$\nabla^4\phi = 64\beta, \quad (5)$$

we have

$$64\beta r\,dr = d\left\{r\frac{d}{dr}\left[\frac{1}{r}\frac{d}{dr}\left(r\frac{d\phi}{dr}\right)\right]\right\} \quad (6)$$

$$32\beta r^2 + C_1 = r\frac{d}{dr}\left[\frac{1}{r}\frac{d}{dr}\left(r\frac{d\phi}{dr}\right)\right] \quad (7)$$

$$\left(32\beta r + \frac{C_1}{r}\right)dr = d\left[\frac{1}{r}\frac{d}{dr}\left(r\frac{d\phi}{dr}\right)\right] \quad (8)$$

$$16\beta r^2 + C_1\ln r + C_2 = \frac{1}{r}\frac{d}{dr}\left(r\frac{d\phi}{dr}\right) \quad (9)$$

$$(16\beta r^3 + C_1 r\ln r + C_2 r)\,dr = d\left(r\frac{d\phi}{dr}\right). \quad (10)$$

Now use

$$\int r\ln r\,dr = \tfrac{1}{2}r^2\ln r - \tfrac{1}{4}r^2 \quad (11)$$

to obtain

$$4\beta r^4 + C_1(\tfrac{1}{2}r^2\ln r - \tfrac{1}{4}r^2) + \tfrac{1}{2}C_2 r^2 + C_3 = r\frac{d\phi}{dr} \quad (12)$$

$$\left(4\beta r^3 + C_1' r\ln r + C_2' r + \frac{C_3}{r}\right)dr = d\phi \quad (13)$$

$$\phi(r) = \beta r^4 + C_1'(\tfrac{1}{2}r^2\ln r - \tfrac{1}{4}r^2) + \tfrac{1}{2}C_2' r^2 + C_3\ln r + C_4$$
$$= \beta r^4 + ar^2 + b + (cr^2 + d)\ln\left(\frac{r}{R}\right). \quad (14)$$

The homogeneous biharmonic equation can be separated and solved in 2-D BIPOLAR COORDINATES.

Biharmonic Operator

Also known as the BILAPLACIAN.

$$\nabla^4 = (\nabla^2)^2.$$

In n-D space,

$$\nabla^4\left(\frac{1}{r}\right) = \frac{3(15 - 8n + n^2)}{r^5}.$$

Bilaplacian

BIHARMONIC OPERATOR

Bilinear Basis

A bilinear basis is a BASIS, which satisfies the conditions

$$(a\mathbf{x} + b\mathbf{y})\cdot\mathbf{z} = a(\mathbf{x}\cdot\mathbf{z}) + b(\mathbf{y}\cdot\mathbf{z})$$

$$\mathbf{z} \cdot (a\mathbf{x} + b\mathbf{y}) = a(\mathbf{z} \cdot \mathbf{x}) + b(\mathbf{z} \cdot \mathbf{y}),$$

See also BASIS, BILINEAR FUNCTION, MULTILINEAR BASIS

Bilinear Form

A bilinear form on a REAL VECTOR SPACE is a function

$$b : V \times V \to \mathbb{R}$$

that satisfies the following axioms for any scalar α and any choice of vectors v, w, v_1, v_2, w_1 and w_2.

1. $b(\alpha v, w) = b(v, \alpha w) = \alpha b(v, w)$
2. $b(v_1 + v_2, w) = b(v_1, w) + b(v_2, w)$
3. $b(v, w_1 + w_2) = b(v, w_1) = +b(v, w_2)$.

For example, the function $b((x_1, x_2), (y_1, y_2)) = x_1 y_2 + x_2 y_1$ is a bilinear form on $\mathbb{R}^2$.

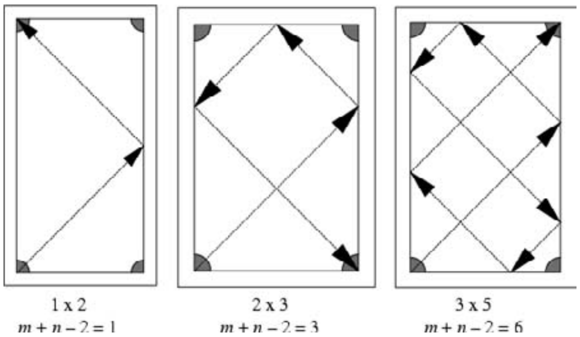
On a COMPLEX VECTOR SPACE, a bilinear form takes values in the COMPLEX NUMBERS. In fact, a bilinear form can take values in any VECTOR SPACE, since the axioms make sense as long as VECTOR ADDITION and SCALAR MULTIPLICATION are defined.

See also BILINEAR FUNCTION, MULTILINEAR FORM, SYMMETRIC BILINEAR FORM, VECTOR SPACE

Bilinear Function

A function of two variables is bilinear if it is linear with respect to each of its variables. The simplest example is $f(x, y) = xy$.

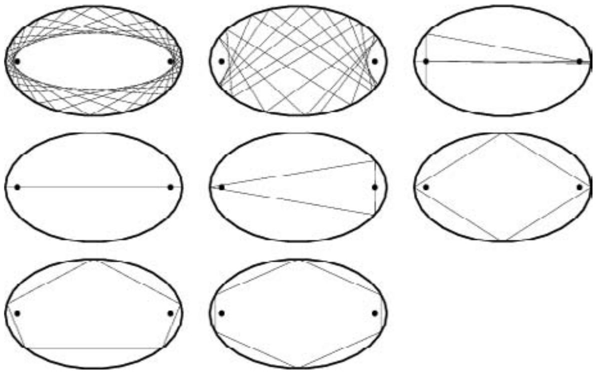
See also BILINEAR BASIS, LINEAR FUNCTION, SYMMETRIC BILINEAR FORM



Billiard Table Problem

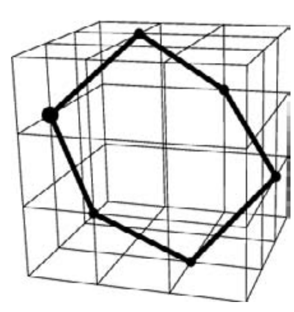
BILLIARDS

Billiards

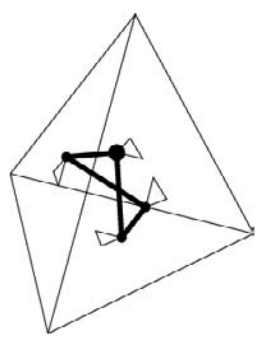


The game of billiards is played on a RECTANGULAR table (known as a billiard table) upon which balls are placed. One ball (the "cue ball") is then struck with the end of a "cue" stick, causing it to bounce into other balls and REFLECT off the sides of the table. Real billiards can involve spinning the ball so that it does not travel in a straight LINE, but the mathematical study of billiards generally consists of REFLECTIONS in which the reflection and incidence angles are the same. However, strange table shapes such as CIRCLES and ELLIPSES are often considered.

Many interesting problems can arise in the detailed study of billiards trajectories. For example, any smooth plane convex set has at least two DOUBLE NORMALS, so there are always two distinct "to and fro" paths for any smoothly curved table. More amazingly, there are always $\phi(k)$ distinct k-gonal periodic orbits on smooth billiard table, where $\phi(k)$ is the TOTIENT FUNCTION (Croft *et al.* 1991, p. 16). This gives Steinhaus's result that there are always two distinct periodic triangular orbits (Croft and Swinnerton-Dyer 1963) as a special case. Analysis of billiards path can involve sophisticated use of ERGODIC THEORY and DYNAMICAL SYSTEMS.



Given a rectangular billiard table with only corner pockets and sides of INTEGER lengths m and n (with m and n RELATIVELY PRIME), a ball sent at a 45° angle from a corner will be pocketed in another corner after $m + n - 2$ bounces (Steinhaus 1983, p. 63; Gardner 1984, pp. 211–14). Steinhaus (1983, p. 64) also gives a method for determining how to hit a billiard ball such that it caroms off all four sides before hitting a second ball (Knaster and Steinhaus 1946, Steinhaus 1948).



ALHAZEN'S BILLIARD PROBLEM seeks to find the point at the edge of a circular "billiards" table at which a cue ball at a given point must be aimed in order to carom once off the edge of the table and strike another ball at a second given point. It was not until 1997 that Neumann proved that the problem is insoluble using a COMPASS and RULER construction.

On an ELLIPTICAL billiard table, the ENVELOPE of a trajectory is a smaller ELLIPSE, a HYPERBOLA, a LINE through the FOCI of the ELLIPSE, or a closed polygon (Steinhaus 1983, pp. 239 and 241; Wagon 1991). The closed polygon case is related to PONCELET'S PORISM.

The only closed billiard path of a single circuit in an ACUTE TRIANGLE is the PEDAL TRIANGLE. There are an infinite number of multiple-circuit paths, but all segments are parallel to the sides of the PEDAL TRIANGLE. There exists a closed billiard path inside a CYCLIC QUADRILATERAL if its CIRCUMCENTER lies inside the quadrilateral (Wells 1991).

There are four identical closed billiard paths inside and touching each face of a CUBE such that each leg on the path has the same length (Hayward 1962; Steinhaus 1979; Steinhaus 1983; Gardner 1984, pp. 33–5; Wells 1991). This path is in the form of a chair-shaped hexagon, and each leg has length $\sqrt{3}/3$. For a unit cube, one such path has vertices (0, 2/3, 2/3), (1/3, 1, 1/3), (2/3, 2/3, 0), (1, 1/3, 1/3), (2/3, 0, 2/3), (1/3, 1/3, 1). Lewis Carroll (Charles Dodgson) also considered this problem (Weaver 1954).

There are three identical closed billiard paths inside and touching each face of a TETRAHEDRON such that each leg of the path has the same length (Gardner 1984, pp. 35–6; Wells 1991). These were discovered by J. H. Conway and independently by Hayward (1962). The vertices of the path are appropriately chosen vertices of equilateral triangles in each facial plane which are scaled by a factor of 1/10. For a tetrahedron with unit side lengths, each leg has length $\sqrt{10}/10$. For a tetrahedron with vertices (0, 0, 0), (0, $\sqrt{2}/2$, $\sqrt{2}/2$), ($\sqrt{2}/2$, 0, $\sqrt{2}/2$), ($\sqrt{2}/2$, $\sqrt{2}/2$, 0), the vertices of one such path are ($3\sqrt{2}/20$, $7\sqrt{2}/20$, $\sqrt{2}/5$), ($3\sqrt{2}/20$, $3\sqrt{2}/20$, $3\sqrt{2}/10$), ($7\sqrt{2}/20$, $3\sqrt{2}/20$, $\sqrt{2}/5$), ($7\sqrt{2}/20$, $7\sqrt{2}/20$, $3\sqrt{2}/10$).

Conway has shown that period orbits exist in all TETRAHEDRA, but it is not known if there are periodic orbits in every POLYHEDRON (Croft *et al.* 1991, p. 16).

Billion

The word billion denotes different numbers in American and British usage. In the American system, one billion equals 10^9. In the British, French, and German systems, one billion equals 10^{12}. Fortunately, in recent years, the "American" system has become common in both the United States and Britain.

Bimagic Cube

A bimagic cube of order 25 is known.

See also Magic Cube

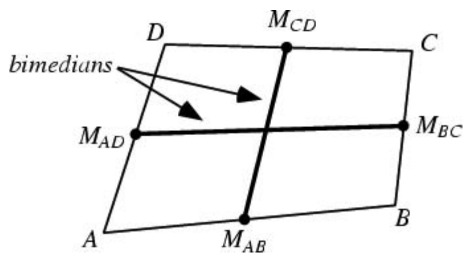
References

Hendricks, J. R. *A Bimagic Cube: Order 25.* Published by the author, 2000.

Bimagic Square

16	41	36	5	27	62	55	18
26	63	54	19	13	44	33	8
1	40	45	12	22	51	58	31
23	50	59	30	4	37	48	9
38	3	10	47	49	24	29	60
52	21	32	57	39	2	11	46
43	14	7	34	64	25	20	53
61	28	17	56	42	15	6	35

If replacing each number by its square in a magic square produces another magic square, the square is said to be a bimagic square. Bimagic squares are also called doubly magic squares, and are 2-multimagic squares.



The first known bimagic square (shown above) has order 8 with magic constant 260 for addition and 11,180 after squaring. It is believed that no bimagic squares of order less than 8 exists (Benson and Jacoby 1976), and Hendricks (1998) shows that a bimagic square of order 3 is impossible for *any* set of numbers except the trivial case of using the same number 9 times.

See also Magic Square, Multimagic Square, Trimagic Square

Bimedian

A LINE SEGMENT joining the MIDPOINTS of opposite sides of a QUADRILATERAL or TETRAHEDRON.

VARIGNON'S THEOREM states that the bimedians of a QUADRILATERAL bisect each other (left figure). In addition, the three bimedians of a tetrahedron are CONCURRENT and bisect each other (right figure; Altshiller-Court 1979, p. 48).

Bimodal Distribution

A STATISTICAL DISTRIBUTION having two separated peaks.

See also UNIMODAL DISTRIBUTION

Bimonster

The wreathed product of the MONSTER GROUP by $\mathbb{Z}_2$.

The bimonster is a quotient of the COXETER GROUP with the above COXETER-DYNKIN DIAGRAM. This had been conjectured by Conway, but was proven around 1990 by Ivanov and Norton. If the parameters p, q, r in Coxeter's NOTATION $[3^{p,q,r}]$ are written side by side, the bimonster can be denoted by the BEAST NUMBER 666.

Bin

An interval into which a given data point does or does not fall.

See also BIN-PACKING PROBLEM, HISTOGRAM

Binary

The BASE 2 method of counting in which only the digits 0 and 1 are used. In this BASE, the number 1011 equals $1 \cdot 2^0 + 1 \cdot 2^1 + 0 \cdot 2^2 + 1 \cdot 2^3 = 11$. This BASE is used in computers, since all numbers can be simply REPRESENTED AS a string of electrically pulsed ons and offs. The following table gives the binary equivalents of the first few decimal numbers.

1	1	11	1011	21	10101
2	10	12	1100	22	10110
3	11	13	1101	23	10111
4	100	14	1110	24	11000
5	101	15	1111	25	11001
6	110	16	10000	26	11010
7	111	17	10001	27	11011
8	1000	18	10010	28	11100
9	1001	19	10011	29	11101
10	1010	20	10100	30	11110

A NEGATIVE $-n$ is most commonly REPRESENTED AS the complement of the POSITIVE number $n-1$, so $-11 = 00001011_2$ would be written as the complement of $10 = 00001010_2$, or 11110101. This allows addition to be carried out with the usual carrying and the left-most digit discarded, so $17 - 1 = 6$ gives

$$\begin{array}{rr} 00010001 & 17 \\ \underline{11110101} & \underline{-11} \\ 00000110 & 6 \end{array}$$

The number of times k a given binary number $b_n \ldots b_2 b_1 b_0$ is divisible by 2 is given by the position of the first $b_k = 1$ counting from the right. For example, $12 = 1100$ is divisible by 2 twice, and $13 = 1101$ is divisible by 2 0 times.

The number of 1s $N(1, n)$ in the binary representation of a number is given by

$$N(1, n) = n - \text{gde}(n!, 2) = n - \sum_{k=1}^{\lfloor \log_2 n \rfloor} \left\lfloor \frac{n}{2^k} \right\rfloor, \quad (1)$$

where $\text{gde}(n!, 2)$ is the GREATEST DIVIDING EXPONENT of 2 with respect to $n!$. This is a special application of the general result that the POWER of a PRIME p dividing a FACTORIAL (Graham *et al.* 1990, Vardi 1991). Writing $a(n)$ for $N(1, n)$, the number of 1s is also given by the RECURRENCE RELATION

$$a(2n) = a(n) \quad (2)$$

$$a(2n+1) = a(n) + 1, \quad (3)$$

with $a(0) = 0$, and by

$$N(1, n) = 2n - \log_2(d), \quad (4)$$

where d is the DENOMINATOR of

$$\frac{1}{n!} \left[\frac{d^n}{dx^n} (1-x)^{-1/2} \right]_{x=0}. \quad (5)$$

For $n = 1, 2, ...$, the first few values are 1, 1, 2, 1, 2, 2, 3, 1, 2, 2, 3, ... (Sloane's A000120; Smith 1966, Graham 1970, McIlroy 1974).

Unfortunately, the storage of binary numbers in computers is not entirely standardized. Because computers store information in 8-bit bytes (where a bit is a single binary digit), depending on the "word size" of the machine, numbers requiring more than 8 bits must be stored in multiple bytes. The usual FORTRAN77 integer size is 4 bytes long. However, a number REPRESENTED AS (byte1 byte2 byte3 byte4) in a VAX would be read and interpreted as (byte4 byte3 byte2 byte1) on a Sun. The situation is even worse for floating point (real) numbers, which are represented in binary as a MANTISSA and CHARACTERISTIC, and worse still for long (8-byte) reals!

Binary multiplication of single bit numbers (0 or 1) is equivalent to the AND operation, as can be seen in the following MULTIPLICATION TABLE.

×	0	1
0	0	0
1	0	1

Binary Bracketing

A binary bracketing is a BRACKETING built up entirely of binary operations. The number of binary bracketings of n letters (CATALAN'S PROBLEM) are given by the CATALAN NUMBERS C_{n-1}, where

$$C_n \equiv \frac{1}{n+1} \binom{2n}{n} = \frac{1}{n+1} \frac{(2n)!}{n!^2} = \frac{(2n)!}{(n+1)!n!},$$

where $\binom{2n}{n}$ denotes a BINOMIAL COEFFICIENT and $n!$ is the usual FACTORIAL, as first shown by Catalan in 1838. For example, for the four letters a, b, c, and d there are five possibilities: $((ab)c)d$, $(a(bc))d$, $(ab)(cd)$, $a((bc)d$, and $a(b(cd))$, written in shorthand as $((xx)x)x$, $(x(xx))x$, $(xx)(xx)$, $x((xx)x$, and $x(x(xx))$.

Binary Carry Sequence

The sequence $a(n)$ given by the exponents of the highest power of 2 dividing n, i.e., the number of trailing 0s in the BINARY representation of n. For $n = 1, 2, ...$, the first few are 0, 1, 0, 2, 0, 1, 0, 3, 0, 1, 0, 2, ... (Sloane's A007814). Amazingly, this corresponds to one less than the number of disk to be moved at nth step of optimal solution to TOWERS OF HANOI problem, 1, 2, 1, 3, 1, 2, 1, 4, 1, 2, 1, ... (Sloane's A001511).

The anti-PARITY of this sequence is given by 1, 0, 1, 1, 1, 0, 1, 0, 1, 0, 1, 1, ... (Sloane's A035263) which, amazingly, also corresponds to the ACCUMULATION POINT of 2^n cycles through successive bifurcations.

Binary Operation

This entry contributed by J. BRAD WEATHERLY

A binary operation on a nonempty set A is a map $f : A \times A \to A$, such that f is defined for every element in A and the image of f is unique. Examples of binary operations on A from $A \times A$ to A include + and -.

See also BINARY OPERATOR

Binary Operator

An OPERATOR defined on a set S which takes two elements from S as inputs and returns a single element of S. Binary operators are called compositions by Rosenfeld (1968). Sets possessing a binary multiplication operation include the GROUP, GROUPOID, MONOID, QUASIGROUP, and SEMIGROUP. Sets possessing both a binary multiplication and a binary addition operation include the DIVISION ALGEBRA, FIELD, RING, RINGOID, SEMIRING, and UNIT RING.

Binary Quadratic Form

A QUADRATIC FORM in two variables having the form

$$Q(x, y) = a_{11}x^2 + 2a_{12}xy + a_{22}y^2. \quad (1)$$

Consider a binary quadratic form with real coefficients a_{11}, a_{12}, and a_{22}, determinant

$$D \equiv a_{11}a_{22} - a_{12}^2 = 1, \quad (2)$$

and $a_{11} > 0$. Then $Q(x, y)$ is POSITIVE DEFINITE. An important result states that exist two integers x and y not both 0 such that

$$Q(x, y) \leq \frac{2}{\sqrt{3}} \quad (3)$$

for all values of a_{ij} satisfying the above constraint (Hilbert and Cohn-Vossen 1999, p. 39).

Binary Tree

A TREE with two BRANCHES at each FORK and with one or two LEAVES at the end of each BRANCH. (This definition corresponds to what is sometimes known as an "extended" binary tree.) The height of a binary tree is the number of levels within the TREE. For a binary tree of height H with n nodes,

$$H \leq n \leq 2^H - 1.$$

These extremes correspond to a balanced tree (each node except the LEAVES has a left and right CHILD, and all LEAVES are at the same level) and a degenerate tree (each node has only one outgoing BRANCH), respectively. For a search of data organized into a binary tree, the number of search steps $S(n)$ needed to find an item is bounded by

$$\lg n \leq S(n) \leq n.$$

Partial balancing of an arbitrary tree into a so-called AVL binary search tree can improve search speed.

The number of binary trees with n internal nodes is the CATALAN NUMBER C_n (Sloane's A000108), and the number of binary trees of height b is given by Sloane's A001699. The numbers of binary trees on $n = 1, 2, \ldots$ nodes (i.e., n-node trees having VERTEX DEGREE either 1 or 3; also called 3-Cayley trees, 3-valent trees, or boron trees) are 1, 1, 0, 1, 0, 1, 0, 1, 0, 2, 0, 2, 0 ,4, 0, 6, 0, 11, ... (Sloane's A052120).

Binet Forms

The two RECURRENCE SEQUENCES

$$U_n = mU_{n-1} + U_{n-2} \tag{1}$$

$$V_n = mV_{n-1} + V_{n-2} \tag{2}$$

with $U_0 = 0$, $U_1 = 1$ and $V_0 = 2$, $V_1 = m$, can be solved for the individual U_n and V_n. They are given by

$$U_n = \frac{\alpha^n - \beta^n}{\Delta} \tag{3}$$

$$V_n = \alpha^n + \beta^n, \tag{4}$$

where

$$\Delta \equiv \sqrt{m^2 + 4} \tag{5}$$

$$\alpha \equiv \frac{m + \Delta}{2} \tag{6}$$

$$\beta \equiv \frac{m - \Delta}{2}. \tag{7}$$

A useful related identity is

$$U_{n-1}+U_{n+1}=V_n. \quad (8)$$

BINET'S FIBONACCI NUMBER FORMULA is a special case of the Binet form for U_n corresponding to $m=1$.

See also BINET'S FIBONACCI NUMBER FORMULA, FIBONACCI Q-MATRIX

Binet's Fibonacci Number Formula

A special case of the U_n BINET FORM with $m=1$, corresponding to the nth FIBONACCI NUMBER,

$$F_n=\frac{(1+\sqrt{5})^n-(1-\sqrt{5})^n}{2^n\sqrt{5}}.$$

It was derived by Binet in 1843, although the result was known to Euler and to Daniel Bernoulli more than a century earlier.

Binet's Log Gamma Formulas

Binet's first formula for $\ln\Gamma(z)$, where $\Gamma(z)$ is a GAMMA FUNCTION, is given by

$$\ln\Gamma(z)=(z-\tfrac{1}{2})\ln z-z+\tfrac{1}{2}\ln(2\pi)+\int_0^\infty[(e^t-1)^{-1}-t^{-1}+\tfrac{1}{2}]t^{-1}e^{-tz}\,dt$$

for $\Re[z]>0$ (Erdélyi *et al.* 1981, p. 21). Binet's second formula is

$$\ln\Gamma(z)=\left(z-\tfrac{1}{2}\right)\ln z-z+\tfrac{1}{2}\ln(2\pi)+2\int_0^\infty\frac{\tan\left(\frac{t}{2}\right)}{e^{2\pi t}-1}\,dt$$

for $\Re[z]>0$ (Erdélyi *et al.* 1981, p. 22; Whittaker and Watson 1990, p. 251).

See also GAMMA FUNCTION, MALMSTÉN'S FORMULA

References

Binet-Cauchy Identity

The algebraic identity

$$\left(\sum_{i=1}^n a_ic_i\right)\left(\sum_{i=1}^n b_id_i\right)-\left(\sum_{i=1}^n a_id_i\right)\left(\sum_{i=1}^n b_ic_i\right)=\sum_{1\le i\le j\le n}(a_ib_j-a_jb_i)(c_id_j-c_jd_i). \quad (1)$$

Letting $c_i=a_i$ and $d_i=b_i$ gives LAGRANGE'S IDENTITY. The identity can be coded in *Mathematica* as follows.

```
<<DiscreteMath`Combinatorica`;
 BinetCauchyId[n_] :=  Module[{
  aa = Array[a, n], bb = Array[b, n],
  cc = Array[c, n], dd = Array[d, n]
  },
  aa.cc bb.dd - aa.dd bb.cc ==
           Plus   @@   ((a[#1]b[#2]   -
a[#2]b[#1])(c[#1]d[#2]  -  c[#2]d[#1])  &  @@@
KSubsets[Range[n], 2])
 ]
```

The $n=2$ case then gives

$$(a_1c_1+a_2c_2)(b_1d_1+b_2d_2)-(b_1c_1+b_2c_2)(a_1d_1+a_2d_2)=(a_1b_2-a_2b_1)(c_1d_2-c_2d_1). \quad (2)$$

The $n=3$ case is equivalent to the vector identity

$$(\mathbf{A}\times\mathbf{B})\cdot(\mathbf{C}\times\mathbf{D})=(\mathbf{A}\cdot\mathbf{C})(\mathbf{B}\cdot\mathbf{D})-(\mathbf{A}\cdot\mathbf{D})(\mathbf{B}\cdot\mathbf{C}), \quad (3)$$

where $\mathbf{A}\cdot\mathbf{B}$ is the DOT PRODUCT and $\mathbf{A}\times\mathbf{B}$ is the CROSS PRODUCT. Note that this identity itself is sometimes known as LAGRANGE'S IDENTITY.

See also LAGRANGE'S IDENTITY

Binomial

A POLYNOMIAL with 2 terms.

See also BINOMIAL COEFFICIENT, MONOMIAL, POLYNOMIAL, TRINOMIAL

Binomial Coefficient

The number of ways of picking n unordered outcomes from N possibilities, also known as a COMBINATION or combinatorial number. The symbols ${}_NC_n$ and $\binom{N}{n}$ are used to denote a binomial coefficient, and are sometimes read as "N CHOOSE n." The value of the binomial coefficient is given by

$$_N C_n \equiv \binom{N}{n} \equiv \frac{N!}{(N-n)!n!}, \qquad (1)$$

where $n!$ denotes a FACTORIAL. Writing the FACTORIAL as a GAMMA FUNCTION $n! = \Gamma(n+1)$ allows the binomial coefficient to be generalized to non-integral arguments.

The binomial coefficients form the rows of PASCAL'S TRIANGLE, and the number of LATTICE PATHS from the ORIGIN $(0, 0)$ to a point (a, b) is the binomial coefficient $\binom{a+b}{a}$ (Hilton and Pedersen 1991).

For a POSITIVE INTEGER n, the BINOMIAL THEOREM gives

$$(x+a)^n = \sum_{k=0}^{n} \binom{n}{k} x^k a^{n-k}. \qquad (2)$$

The FINITE DIFFERENCE analog of this identity is known as the CHU-VANDERMONDE IDENTITY. A similar formula holds for NEGATIVE INTEGERS,

$$(x+a)^{-n} = \sum_{k=0}^{\infty} \binom{-n}{k} x^k a^{-n-k}. \qquad (3)$$

There are a number of elegant BINOMIAL SUMS.

The binomial coefficients satisfy the identities

$$\binom{n}{0} = \binom{n}{n} = 1 \qquad (4)$$

$$\binom{n}{k} = \binom{n}{n-k} = (-1)^k \binom{k-n-1}{k} \qquad (5)$$

$$\binom{n+1}{k} = \binom{n}{k} + \binom{n}{k-1}. \qquad (6)$$

As shown by Kummer in 1852, if p^k is the largest power of a PRIME p that divides $\binom{n+k}{k}$, where n and k are nonnegative integers, then k is the number of carries that occur when k is added to n in base p (Graham *et al.* 1989, Exercise 5.36, p. 245; Ribenboim 1989; Vardi 1991, p. 68). Kummer's result can also be stated in the form that the exponent of a PRIME p dividing $\binom{n}{m}$ is given by the number of integers $j \geq 0$ for which

$$\operatorname{frac}(m/p^j) > \operatorname{frac}(n/p^j), \qquad (7)$$

where $\operatorname{frac}(x)$ denotes the FRACTIONAL PART of x. This inequality may be reduced to the study of the exponential sums $\Sigma_n \Lambda(n) e(x/n)$, where $\Lambda(n)$ is the MANGOLDT FUNCTION. Estimates of these sums are given by Jutila (1974, 1975), but recent improvements have been made by Granville and Ramare (1996).

R. W. Gosper showed that

$$f(n) = \binom{n-1}{\frac{1}{2}(n-1)} \equiv (-1)^{(n-1)/2} \pmod{n} \qquad (8)$$

for all PRIMES, and conjectured that it holds *only* for PRIMES. This was disproved when Skiena (1990) found it also holds for the COMPOSITE NUMBER $n = 3 \times 11 \times 179$. Vardi (1991, p. 63) subsequently showed that $n = p^2$ is a solution whenever p is a WIEFERICH PRIME and that if $n = p^k$ with $k > 3$ is a solution, then so is $n = p^{k-1}$. This allowed him to show that the only solutions for COMPOSITE $n < 1.3 \times 10^7$ are 5907, 1093^2, and 3511^2, where 1093 and 3511 are WIEFERICH PRIMES.

Consider the binomial coefficients $f(n) = \binom{2n-1}{n}$, the first few of which are 1, 3, 10, 35, 126, ... (Sloane's A001700). The GENERATING FUNCTION is

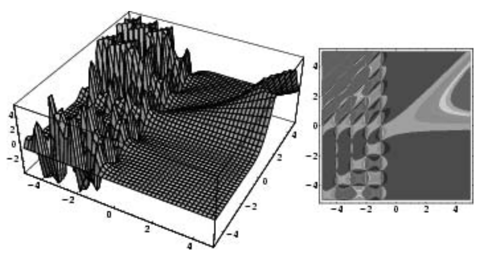
$$\frac{1}{2}\left[\frac{1}{\sqrt{1-4x}} - 1\right] = x + 3x^2 + 10x^3 + 35x^4 + \ldots. \qquad (9)$$

These numbers are SQUAREFREE only for $n = 2$, 3, 4, 6, 9, 10, 12, 36, ... (Sloane's A046097), with no others known. It turns out that $f(n)$ is divisible by 4 unless n belongs to a 2-AUTOMATIC SET S_2, which happens to be the set of numbers whose BINARY representations contain at most two 1s: 1, 2, 3, 4, 5, 6, 8, 9, 10, 12, 16, 17, 18, ... (Sloane's A048645). Similarly, $f(n)$ is divisible by 9 unless n belongs to a 3-AUTOMATIC SET S_3, consisting of numbers n for which the representation of $2n$ in TERNARY consists entirely of 0s and 2s (except possibly for a pair of adjacent 1s; D. Wilson, A. Karttunen). The initial elements of S3 are 1, 2, 3, 4, 6, 7, 9, 10, 11, 12, 13, 18, 19, 21, 22, 27, ... (Sloane's A051382). If $f(n)$ is squarefree, then n must belong to $S = S_2 \cap S_3$. It is very probable that S is finite, but no proof is known. Now, squares larger than 4 and 9 might also divide $f(n)$, but by eliminating these two alone, the only possible n for $n \leq 2^6 4$ are 1, 2, 3, 4, 6, 9, 10, 12, 18, 33, 34, 36, 40, 64, 66, 192, 256, 264, 272, 513, 514, 516, 576 768, 1026, 1056, 2304, 16392, 65664, 81920, 532480, and 545259520. All of these but the last have been checked (D. Wilson), establishing that there are no other n such that $f(n)$ is squarefree for $n \leq 545, 259, 520$.

Erdos showed that the binomial coefficient $\binom{n}{k}$, with $3 \leq k \leq n/2$ is a POWER of an INTEGER for the single case $\binom{50}{3} = 140^2$ (Le Lionnais 1983, p. 48). Binomial coefficients $T_{n-1} = \binom{n}{2}$ are squares a^2 when a^2 is a TRIANGULAR NUMBER, which occur for $a = 1$, 6, 35, 204, 1189, 6930, ... (Sloane's A001109). These values of a have the corresponding values $n = 2$, 9, 50, 289, 1682, 9801, ... (Sloane's A052436).

The binomial coefficients $\binom{n}{\lfloor n/2 \rfloor}$ are called CENTRAL BINOMIAL COEFFICIENTS, where $\lfloor x \rfloor$ is the FLOOR FUNCTION, although the subset of coefficients $\binom{2n}{n}$ is sometimes also given this name. Erdos and Graham (1980, p. 71) conjectured that the CENTRAL BINOMIAL COEFFICIENT $\binom{2n}{n}$ is *never* SQUAREFREE for $n > 4$, and this is sometimes known as the ERDOS SQUAREFREE CONJECTURE. SÁRKOZY'S THEOREM (Sárkozy 1985) provides a partial solution which states that the BINOMIAL COEFFICIENT $\binom{2n}{n}$ is never SQUAREFREE for

all sufficiently large $n \geq n_0$ (Vardi 1991). Granville and Ramare (1996) proved that the *only* SQUAREFREE values are $n = 2$ and 4. Sander (1992) subsequently showed that $\binom{2n\pm d}{n}$ are also never SQUAREFREE for sufficiently large n as long as d is not "too big."



For p, q, and r distinct PRIMES, then the function (8) satisfies

$$f(pqr)f(p)f(q)f(r) \equiv f(pq)f(pr)f(qr) \pmod{pqr} \qquad (10)$$

(Vardi 1991, p. 66).

Most binomial coefficients $\binom{n}{k}$ with $n \geq 2k$ have a prime factor $p \leq n/k$, and Lacampagne *et al.* (1993) conjecture that this inequality is true for all $n > 17.125k$, or more strongly that any such binomial coefficient has LEAST PRIME FACTOR $p \leq n/k$ or $p \leq 17$ with the exceptions $\binom{62}{6}$, $\binom{959}{56}$, $\binom{474}{66}$, $\binom{284}{28}$ for which $p = 19$, 19, 23, 29 (Guy 1994, p. 84).

The binomial coefficient $\binom{m}{n}$ (mod 2) can be computed using the XOR operation n XOR m, making PASCAL'S TRIANGLE mod 2 very easy to construct.

The binomial coefficient "function" can be defined as

$$C(x, y) \equiv \frac{x!}{y!(x-y)} \qquad (11)$$

(Fowler 1996), shown above. It has a very complicated GRAPH for NEGATIVE x and y which is difficult to render using standard plotting programs.

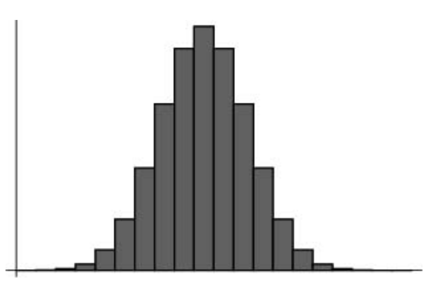
Binomial Differential Equation

The ORDINARY DIFFERENTIAL EQUATION



$$(y')^m = f(x, y)$$

(Hille 1969, p. 675; Zwillinger 1997, p. 120).

References

Hille, E. *Lectures on Ordinary Differential Equations.* Reading, MA: Addison-Wesley, 1969.

Binomial Distribution

The binomial distribution gives the probability distribution $P_p(n|N)$ of obtaining exactly n successes out of N BERNOULLI TRIALS (where the result of each BERNOULLI TRIAL is true with probability p and false with probability $q = 1 - p$). The binomial distribution is therefore given by

$$P_p(n|N) = \binom{N}{n} p^n (1-p)^{N-n} = \frac{N!}{n!(N-n)!} p^n q^{N-n}. \quad (1)$$

The above plot shows the distribution of n successes out of $N = 20$ trials with $p = q = 1/2$. Steinhaus (1983, pp. 25–8) considers the expected number of squares $S(n, N, s)$ containing a given number of grains n on board of size s after random distribution of N of grains,

$$S(n, N, s) = sP_{1/s}(n|N). \quad (2)$$

Taking $N = s = 64$ gives the results summarized in the following table.

S	n
0	23.3591
1	23.7299
2	11.8650
3	3.89221
4	0.942162
5	0.179459
6	0.0280109
7	0.0036840
8	4.16639×10^{-4}
9	4.11495×10^{-5}
10	3.59242×10^{-6}

The probability of obtaining *more* successes than the n observed in a binomial distribution is

$$P = \sum_{k=n+1}^{N} \binom{N}{k} p^k (1-p)^{N-k} = I_p(n+1, N-n), \quad (3)$$

where

$$I_x(a, b) \equiv \frac{B(x; a, b)}{B(a, b)}, \quad (4)$$

$B(a, b)$ is the BETA FUNCTION, and $B(x; a, b)$ is the incomplete BETA FUNCTION.

The CHARACTERISTIC FUNCTION for the binomial distribution is

$$\phi(t) = (q + pe^{it})^n \quad (5)$$

(Papoulis 1984, p. 154). The MOMENT-GENERATING FUNCTION M for the distribution is

$$M(t) = \langle e^{tn} \rangle = \sum_{n=0}^{N} e^{tn} \binom{N}{n} p^n q^{N-n}$$

$$= \sum_{n=0}^{N} \binom{N}{n} (pe^t)(1-p)^{N-n} = [pe^t + (1-p)]^N \quad (6)$$

$$M'(t) = N[pe^t + (1-p)]^{N-1}(pe^t) \quad (7)$$

$$M''(t) = N(N-1)[pe^t + (1-p)]^{N-2}(pe^t)^2$$

$$+N[pe^t+(1-p)]^{N-1}(pe^t). \quad (8)$$

The MEAN is

$$\mu = M'(0) = N(p+1-p)p = Np. \quad (9)$$

The MOMENTS about 0 are

$$\mu'_1 = \mu = Np \quad (10)$$

$$\mu'_2 = Np(1-p+Np) \quad (11)$$

$$\mu'_3 = Np(1-3p+3Np+2p^2-3NP^2+N^2p^2) \quad (12)$$

$$\mu'_4 = Np(1-7p+7Np+12p^2-18Np^2+6N^2p^2-6p^3 + 11Np^3-6N^2p^3+N^3p^3), \quad (13)$$

so the MOMENTS about the MEAN are

$$\mu_2 = \sigma^2 = [N(N-1)p^2+Np]-(Np)^2 = N^2p^2-Np^2+Np-N^2p^2 = Np(1-p) = Npq \quad (14)$$

$$\mu_3 = \mu'_3 - 3\mu'_2\mu'_1 + 2(\mu_1)^3 = Np(1-p)(1-2p) \quad (15)$$

$$\mu_4 = \mu'_4 - 4\mu'_3\mu'_1 + 6\mu'_2(\mu'_1)^2 - 3(\mu_1)^4 = Np(1-p)[3p^2(2-N)+3p(N-2)+1]. \quad (16)$$

The SKEWNESS and KURTOSIS are

$$\gamma_1 = \frac{\mu_3}{\sigma^3} = \frac{Np(1-p)(1-2p)}{[Np(1-p)]^{3/2}} = \frac{1-2p}{\sqrt{Np(1-p)}} = \frac{q-p}{\sqrt{Npq}} \quad (17)$$

$$\gamma_2 = \frac{\mu_4}{\sigma^4} - 3 = \frac{6p^2-6p+1}{Np(1-p)} = \frac{1-6pq}{Npq}. \quad (18)$$

An approximation to the Bernoulli distribution for large N can be obtained by expanding about the value $\tilde{n}$ where $P(n)$ is a maximum, i.e., where $dP/dn = 0$. Since the LOGARITHM function is MONOTONIC, we can instead choose to expand the LOGARITHM. Let $n \equiv \tilde{n} + \eta$, then

$$\ln[P(n)] = \ln[P(\tilde{n})] + B_1\eta + \tfrac{1}{2}B_2\eta^2 + \tfrac{1}{3!}B_3\eta^3 + \ldots, \quad (19)$$

where

$$B_k = \left[\frac{d^k \ln[P(n)]}{dn^k}\right]_{n=\tilde{n}}. \quad (20)$$

But we are expanding about the maximum, so, by definition,

$$B_1 = \left[\frac{d \ln[P(n)]}{dn}\right]_{n=\tilde{n}} = 0. \quad (21)$$

This also means that B_2 is negative, so we can write $B_2 = -|B_2|$. Now, taking the LOGARITHM of (1) gives

$$\ln[P(n)] = \ln N! - \ln n! - \ln(N-n)! + n \ln p + (N-n)\ln q. \quad (22)$$

For large n and $N-n$ we can use STIRLING'S APPROXIMATION

$$\ln(n!) \approx n \ln n - n, \quad (23)$$

so

$$\frac{d[\ln(n!)]}{dn} \approx (\ln n + 1) - 1 = \ln n \quad (24)$$

$$\frac{d[\ln(N-n)!]}{dn} \approx \frac{d}{dn}[(N-n)\ln(N-n)-(N-n)] = \left[-\ln(N-n)+(N-n)\frac{-1}{N-n}+1\right] = -\ln(N-n), \quad (25)$$

and

$$\frac{d\ln[P(n)]}{dn} \approx -\ln n + \ln(N-n)\ln p - \ln q. \quad (26)$$

To find $\tilde{n}$, set this expression to 0 and solve for n,

$$\ln\left(\frac{N-\tilde{n}}{\tilde{n}}\frac{p}{q}\right) = 0 \quad (27)$$

$$\frac{N-\tilde{n}}{\tilde{n}}\frac{p}{q} = 1 \quad (28)$$

$$(N-\tilde{n})p = \tilde{n}q \quad (29)$$

$$\tilde{n}(q+p) = \tilde{n} = Np, \quad (30)$$

since $p+q=1$. We can now find the terms in the expansion

$$B_2 = \left[\frac{d^2\ln[P(n)]}{dn^2}\right]_{n=\tilde{n}} = -\frac{1}{\tilde{n}} - \frac{1}{N-\tilde{n}} = -\frac{1}{Np} - \frac{1}{N(1-p)} = -\frac{1}{N}\left(\frac{1}{p}+\frac{1}{q}\right) = -\frac{1}{N}\left(\frac{p+q}{pq}\right) = -\frac{1}{Npq} = -\frac{1}{N(1-p)} \quad (31)$$

$$B_3 \equiv \left[\frac{d^3\ln[P(n)]}{dn^3}\right]_{n=\tilde{n}} = -\frac{1}{\tilde{n}^2} - \frac{1}{(N-\tilde{n})^2} = \frac{1}{N^2p^2} - \frac{1}{N^2q^2} = \frac{q^2-p^2}{N^2p^2q^2} = \frac{(1-2p+p^2)-p^2}{N^2p^2(1-p)^2} = \frac{1-2p}{N^2p^2(1-p)^2} \quad (32)$$

$$B_4 \equiv \left[\frac{d^4 \ln[P(n)]}{dn^4}\right]_{n=\tilde{n}} = -\frac{2}{\tilde{n}^3} - \frac{2}{(n-\tilde{n})^3}$$
$$= -2\left(\frac{1}{N^3p^3} + \frac{1}{N^3q^3}\right) = \frac{2(p^3+q^3)}{N^3p^3q^3}$$
$$= \frac{2(p^2 - pq + q^2)}{N^3p^3q^3}$$
$$= \frac{2[p^2 - p(1-p) + (1-2p+p^2)]}{N^3p^3(1-p^3)}$$
$$= \frac{2(3p^2 - 3p + 1)}{N^3p^3(1-p^3)}. \quad (33)$$

Now, treating the distribution as continuous,

$$\lim_{N\to\infty} \sum_{n=0}^{N} P(n) \approx \int P(n)\, dn = \int_{-\infty}^{\infty} P(\tilde{n}+\eta)\, d\eta = 1. \quad (34)$$

Since each term is of order $1/N \sim 1/\sigma^2$ smaller than the previous, we can ignore terms higher than B_2, so

$$P(n) = P(\tilde{n}) e^{-|B_2|\eta^2/2}. \quad (35)$$

The probability must be normalized, so

$$\int_{-\infty}^{\infty} P(\tilde{n})\, e^{-|B_2|\eta^2/2}\, d\eta = P(\tilde{n}) \sqrt{\frac{2\pi}{|B_2|}} = 1, \quad (36)$$

and

$$P(n) = \sqrt{\frac{|B_2|}{2\pi}}\, e^{-|B_2|(n-\tilde{n})^2/2}$$
$$= \frac{1}{\sqrt{2\pi Npq}} \exp\left[-\frac{(n-Np)^2}{2Npq}\right]. \quad (37)$$

Defining $\sigma^2 \equiv Npq$,

$$P(n) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left[-\frac{(n-\tilde{n})^2}{2\sigma^2}\right], \quad (38)$$

which is a GAUSSIAN DISTRIBUTION. For $p \ll 1$, a different approximation procedure shows that the binomial distribution approaches the POISSON DISTRIBUTION. The first CUMULANT is

$$\kappa_1 = np, \quad (39)$$

and subsequent CUMULANTS are given by the RECURRENCE RELATION

$$\kappa_{r+1} = pq\, \frac{d\kappa_r}{dp}. \quad (40)$$

Let x and y be independent binomial RANDOM VARIABLES characterized by parameters n, p and m, p. The CONDITIONAL PROBABILITY of x given that $x+y=k$ is

$$P(x=i|x+y=k) = \frac{P(x=i,\ x+y=k)}{P(x+y=k)}$$
$$= \frac{P(x=i,\ y=k-i)}{P(x+y=k)} = \frac{P(x=i)P(y=k-i)}{P(x+y=k)}$$
$$= \frac{\binom{n}{i} p^i(1-p)^{n-i} \binom{m}{k-i} p^{k-i}(1-p)^{m-(k-i)}}{\binom{n+m}{k} p^k(1-p)^{n+m-k}}$$
$$= \frac{\binom{n}{i}\binom{m}{k-i}}{\binom{n+m}{k}}. \quad (41)$$

Note that this is a HYPERGEOMETRIC DISTRIBUTION.

Binomial Expansion

BINOMIAL SERIES

Binomial Formula

BINOMIAL SERIES, BINOMIAL THEOREM

Binomial Identity

Roman (1984, p. 26) defines "the" binomial identity as the equation

$$p_n(x+y) = \sum_{k=0}^{n} \binom{n}{k} p_k(y) p_{n-k}(x). \quad (1)$$

IFF the sequence $p_n(x)$ satisfies this identity for all y in a FIELD C of characteristic 0, then $p_n(x)$ is an ASSOCIATED SEQUENCE known as a BINOMIAL-TYPE SEQUENCE.

In general, a binomial identity is a formula expressing products of factors as a sum over terms, each including a BINOMIAL COEFFICIENT $\binom{n}{k}$. The prototypical example is the BINOMIAL THEOREM

$$(x+a)^n = \sum_{k=0}^{n} \binom{n}{k} x^k a^{n-k} \quad (2)$$

for $n > 0$. Abel (1826) gave a host of such identities (Riordan 1979, Roman 1984), some of which include

$$(x + y)(x + y - an)^{n-1} = \sum_{k=0}^{n} \binom{n}{k} xy(x-ak)^{k-1}[y-a(n-k)]^{n-k-1}, \quad (3)$$

$$x^{-1}(x+y-na)^n = \sum_{k=0}^{n} \sum_{k=0}^{n} \binom{n}{k} (x-ak)^{k-1}[y-a(n-k)]^{n-k} \quad (4)$$

(Abel 1826, Riordan 1979, p. 18; Roman 1984, pp. 30 and 73), and

$$x^{-1}(x+y)^n = \sum_{k=0}^{n} \binom{n}{k} (x-ak)^{k-1}(y+ak)^{n-k} \quad (5)$$

(Saslaw 1989).

Binomial Number

A number of the form $a^n \pm b^n$, where a, b, and n are integers. They can be factored algebraically

$$a^n - b^n = (a-b)(a^{n-1} + a^{n-2}b + \ldots + ab^{n-2} + b^{n-1}) \quad (1)$$

for all n,

$$a^n + b^n = (a+b)(a^{n-1} - a^{n-2}b + \ldots - ab^{n-2} + b^{n-1}) \quad (2)$$

for n not a power of 2, and

$$a^{nm} - b^{nm} = (a^m - b^m) \times [a^{m(n-1)} + a^{m(n-2)}b^m + \ldots + b^{m(n-1)}]. \quad (3)$$

for all positive integers m, n. For example,

$$a^2 - b^2 = (a-b)(a+b) \quad (4)$$

$$a^3 - b^3 = (a-b)(a^2+ab+b^2) \quad (5)$$

$$a^4 - b^4 = (a-b)(a+b)(a^2+b^2) \quad (6)$$

$$a^5 - b^5 = (a-b)(a^4+a^3b+a^2b^2+ab^3+b^4) \quad (7)$$

$$a^6 - b^6 = (a-b)(a+b)(a^2-ab+b^2)(a^2+ab+b^2) \quad (8)$$

$$a^7 - b^7 = (a-b)(a^6+a^5b+a^4b^2+a^3b^3+a^2b^4+ab^5+b^6) \quad (9)$$

$$a^8 - b^8 = (a-b)(a+b)(a^2+b^2)(a^4+b^4) \quad (10)$$

$$a^9 - b^9 = (a-b)(a^2+ab+b^2)(a^6+a^3b^3+b^6) \quad (11)$$

$$a^{10} - b^{10} = (a-b)(a+b)(a^4-a^3b+a^2b^2-ab^3+b^4) \times (a^4+a^3b+a^2b^2+ab^3+b^4) \quad (12)$$

and

$$a^2 + b^2 = a^2 + b^2 \quad (13)$$

$$a^3 + b^3 = (a+b)(a^2-ab+b^2) \quad (14)$$

$$a^4 + b^4 = a^4 + b^4 \quad (15)$$

$$a^5 + b^5 = (a+b)(a^4-a^3b+a^2b^2-ab^3+b^4) \quad (16)$$

$$a^6 + b^6 = (a^2+b^2)(a^4-a^2b^2+b^4) \quad (17)$$

$$a^7 + b^7 = (a+b)(a^6-a^5b+a^4b^2-a^3b^3+a^2b^4-ab^5+b^6) \quad (18)$$

$$a^8 + b^8 = a^8 + b^8 \quad (19)$$

$$a^9 + b^9 = (a+b)(a^2-ab+b^2)(a^6-a^3b^3+b^6) \quad (20)$$

$$a^{10} + b^{10} = (a^2+b^2)(a^8-a^6b^2+a^4b^4-a^2b^6+b^8). \quad (21)$$

In 1770, Euler proved that if $(a, b) = 1$, then every factor of

$$a^{2^n} + b^{2^n} \quad (22)$$

is either 2 or of the form $2^{n+1}K + 1$. (A number of the form $2^{2^n} + 1$ is called a Fermat number.)

If p and q are primes, then

$$\frac{(a^{pq} - 1)(a - 1)}{(a^p - 1)(a^q - 1)} - 1 \quad (23)$$

is divisible by every prime factor of a^{p-1} not dividing a^{q-1}.

Binomial Polynomial

FALLING FACTORIAL

Binomial Series

For $|x| < 1$,

$$(1+x)^n = \sum_{k=0}^{n} \binom{n}{k} x^k \tag{1}$$

$$= \binom{n}{0} x^0 + \binom{n}{1} x^1 + \binom{n}{2} x^2 + \cdots \tag{2}$$

$$= 1 + \frac{n!}{1!(n-1)!}\, x + \frac{n!}{(n-2)!2!}\, x^2 + \ldots \tag{3}$$

$$= 1 + nx + \frac{n(n-1)}{2}\, x^2 + \ldots. \tag{4}$$

The binomial series also has the CONTINUED FRACTION representation

$$(1+x)^n = \cfrac{1}{1 - \cfrac{nx}{1 + \cfrac{\frac{1\cdot(1+n)}{1\cdot 2}x}{1 + \cfrac{\frac{1\cdot(1-n)}{2\cdot 3}x}{1 + \cfrac{\frac{2(2+n)}{3\cdot 4}x}{1 + \cfrac{\frac{2(2-n)}{4\cdot 5}x}{1 + \cfrac{\frac{3(3+n)}{5\cdot 6}x}{1+\ldots}}}}}}}. \tag{5}$$

Binomial Sums

The important BINOMIAL THEOREM states that

$$\sum_{k=0}^{n} \binom{n}{k} r^k = (1+r)^n. \tag{1}$$

Sums of powers of BINOMIAL COEFFICIENTS

$$a_r(n) = \sum_{k=0}^{n} \binom{n}{k}^r \tag{2}$$

are given by

$$a_1(n) = 2^n \tag{3}$$

$$a_2(n) = \binom{2n}{n} \tag{4}$$

$a_1(n)$ and $a_2(n)$ obey the RECURRENCE RELATION

$$a_1(n+1) - 2a_1(n) = 0 \tag{5}$$

$$(n+1)a_2(n+1) - (4n+2)a_2(n) = 0. \tag{6}$$

Franel (1894, 1895) was the first to obtain recurrences for $a_3 n$ (Riordan 1948, p. 193) and $a_4(n)$,

$$(n+1)^2 a_3(n+1) - (7n^2+7n+2)a_3(n) - 8n^2 a_3(n-1) = 0 \tag{7}$$

(Barrucand 1975, Cusick 1989, Jin and Dickinson 2000)

$$(n+1)^3 a_4(n+1) - 2(2n+1)(3n^2+3n+1)a_4(n) - 4n(4n+1)(4n-1)a_4(n-1) = 0. \tag{8}$$

(Jin and Dickinson 2000). Therefore, $a_3 n$ are sometimes called FRANEL NUMBERS. The sequence for $a_3 n$ cannot be expressed as a fixed number of hypergeometric terms (Petkovsek *et al.* 1996, p. 160), and therefore has no closed-form hypergeometric expression. Perlstadt (1987) found recurrences of length 4 for $r = 5$ and 6, while Schmidt and Yuan (1995) showed that the give recurrences for $r = 3$, 4, 5, and 6 are minimal, are the minimal lengths for $r > 6$ are at least 3. The following table summarizes the first few values of $a_r(n)$ for small r.

k	Sloane	$a_k(n)$
1	A000079	1, 2, 4, 8, 16, 32, 54, ...
2	A000984	1, 2, 6, 20, 70, 252, 924, ...
3	A000172	1, 2, 10, 56, 346, 2252, ...
4	A005260	1, 2, 18, 164, 1810, 21252, ...
5	A005260	1, 2, 34, 488, 9826, 206252, ...

The corresponding alternating series is

$$b_r \equiv \sum_{k=0}^{n} (-1)^k \binom{n}{k}^k = 0. \tag{9}$$

The first few values are

$$b_1(n) = 0 \tag{10}$$

$$b_2(n) = \frac{2^n \sqrt{\pi}}{\Gamma(\frac{1}{2} - \frac{1}{2}n)\Gamma(1 + \frac{1}{2}n)}, \tag{11}$$

$$= \begin{cases} 0 & \text{for } n = 2k \\ (-1)^k \binom{n}{k} & \text{for } n = 2k - 1 \end{cases} \tag{12}$$

$$b_3(n) = \frac{2^n \sqrt{\pi}\Gamma(1 + \frac{3}{2}n)}{n!\Gamma(\frac{1}{2}(1 - n))\Gamma(1 + \frac{1}{2}n)^2} \tag{13}$$

$$= \begin{cases} 0 & \text{for } n = 2k - 1 \\ \frac{(-1)^k (3k)!}{(k!)^3} & \text{for } n = 2k, \end{cases} \tag{14}$$

where $\Gamma(z)$ is the GAMMA FUNCTION, and the odd terms of $b_3(n)$ are given by de Bruijn's $s(3, n)$ with alternating signs.

de Bruijn (1982) has considered the sum

$$s(m, n) = \sum_{k=0}^{2n} (-1)^{k+n} \binom{2n}{k}^m \tag{15}$$

for $m, n \geq 1$. This sum has closed form for $m = 1, 2$, and 3,

$$s(1, n) = 0 \tag{16}$$

$$s(2, n) = \frac{(2n)!}{(n!)^2}, \tag{17}$$

the CENTRAL BINOMIAL COEFFICIENT, giving 1, 2, 6, 20, 70, 252, 924, ... (Sloane's A000984), and

$$s(3, n) = \frac{(3n)!}{(n!)^3}, \tag{18}$$

giving 1, 6, 90, 1680, 36450, 756756, ... (Sloane's A006480; Aizenberg and Yuzhakov 1984). However, there is no similar formula for $m \geq 4$ (Finch). The first few terms of $s(4, n)$ are 1, 14, 786, 61340, 5562130, ... (Sloane's A050983), and for $s(5, n)$ are 1, 30, 5730, 1696800, 613591650, ... (Sloane's A050984).

An interesting generalization of $b_1(n)$ was found by Ruiz (1996),

$$\sum_{k=0}^{\infty} (-1)^k \binom{n}{k} (x - k)^n = n! \tag{19}$$

and

$$\sum_{k=0}^{n} (-1)^k \binom{n}{k} (x - k)^n = n! \tag{20}$$

for positive integer n and all x.

The infinite sum of inverse binomial coefficients has the analytic form

$$\sum_{k=0}^{\infty} \frac{1}{\binom{n}{k}} = {}_2F_1(1, 1; -n; -1) \tag{21}$$

$$= -(n + 1) \int_0^1 \frac{dx}{(1 - x)^{n+2}(x + 1)}, \tag{22}$$

where ${}_2F_1(a, b; c; x)$ is a HYPERGEOMETRIC FUNCTION. In fact, in general,

$$\sum_{k=0}^{\infty} \frac{1}{\binom{n}{k}^p} = {}_{p+1}F_p(\underbrace{1, \ldots, 1}_{p+1}; \underbrace{-n, \ldots, -n}_{p}; (-1)^k) \tag{23}$$

and

$$\sum_{k=0}^{\infty} \frac{(-1)^k}{\binom{n}{k}^p} = {}_{p+1}F_p(\underbrace{1, \ldots, 1)}_{p+1}; \underbrace{-n, \ldots, -n}_{p}; (-1)^{k+1}). \tag{24}$$

A fascinating series of identities involving inverse central binomial coefficients times small powers are given by

$$\sum_{n=1}^{\infty} \frac{1}{\binom{2n}{n}} = \tfrac{1}{27}(2\pi\sqrt{3} + 9) = 0.7363998587\ldots \tag{25}$$

$$\sum_{n=1}^{\infty} \frac{1}{n\binom{2n}{n}} = \tfrac{1}{9}\pi\sqrt{3} = 0.6045997881\ldots \tag{26}$$

$$\sum_{n=1}^{\infty} \frac{1}{n^2\binom{2n}{n}} = \tfrac{1}{3}\zeta(2) = \tfrac{1}{8}\pi^2 \tag{27}$$

$$\sum_{n=1}^{\infty} \frac{1}{n^4\binom{2n}{n}} = \tfrac{17}{36}\zeta(4) = \tfrac{17}{3240}\pi^4 \tag{28}$$

(Comtet 1974, p. 89; Le Lionnais 1983, pp. 29, 30, 41, 36), which follow from the beautiful formula

$$\sum_{n=1}^{\infty} \frac{1}{n^k\binom{2n}{n}} = \tfrac{1}{2}\,{}_{k+1}F_k(\underbrace{1, \ldots, 1}_{k+1}; \tfrac{3}{2}, \underbrace{2, \ldots, 2}_{k-1}; \tfrac{1}{4}) \tag{29}$$

for $k \geq 1$, where $mF_n(a_1, \ldots, a_m; b_1, \ldots, b_n; x)$ is a GENERALIZED HYPERGEOMETRIC FUNCTION. Additional sums of this type include

$$\sum_{n=1}^{\infty} \frac{1}{n^3 \binom{2n}{n}} = \tfrac{1}{18}\pi\sqrt{3}[\psi_1(\tfrac{1}{3}) - \psi_1(\tfrac{2}{3})] - \tfrac{4}{3}\zeta(3) \quad (30)$$

$$\sum_{n=1}^{\infty} \frac{1}{n^5 \binom{2n}{n}}$$

$$= \tfrac{1}{432}\pi\sqrt{3}[\psi_3(\tfrac{1}{3}) - \psi_3(\tfrac{2}{3})] - \tfrac{19}{3}\zeta(5) + \tfrac{1}{9}\zeta(3)\pi^2 \quad (31)$$

$$\sum_{n=1}^{\infty} \frac{1}{n^7 \binom{2n}{n}} = \tfrac{11}{311040}\pi\sqrt{3}[\psi_5(\tfrac{1}{3}) - \psi_5(\tfrac{2}{3})] - \tfrac{493}{24}\zeta(7) + \tfrac{1}{3}\zeta(5)\pi^2$$

$$+ \tfrac{17}{1620}\zeta(3)\pi^4, \quad (32)$$

where $\psi_n(x)$ is the POLYGAMMA FUNCTION and $\zeta(x)$ is the RIEMANN ZETA FUNCTION (Plouffe 1998).

Sums OF THE FORM

$$\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^k \binom{2n}{n}} = \tfrac{1}{2}\, {}_{k+1}F_k(\underbrace{1, \ldots, 1}_{k+1}; \tfrac{3}{2}, \underbrace{2, \ldots, 2}_{k-1}; -\tfrac{1}{4}) \quad (33)$$

can also be simplified (Plouffe) to give the special cases

$$\sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n \binom{2n}{n}} = \tfrac{2}{5}\sqrt{5}\sinh^{-1}(\tfrac{1}{2}) \quad (34)$$

$$\sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n^2 \binom{2n}{n}} = 2[\sinh^{-1}(\tfrac{1}{2})]^2 \quad (35)$$

$$\sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n^3 \binom{2n}{n}} = \tfrac{2}{5}\zeta(3). \quad (36)$$

Other general identities include

$$\frac{(a+b)^n}{a} = \sum_{k=0}^{n} \binom{n}{k} (a-kc)^{k-1}(b+kc)^{n-k} \quad (37)$$

(Prudnikov *et al.* 1986), which gives the BINOMIAL THEOREM as a special case with $c=0$, and

$$\sum_{n=0}^{\infty} \binom{2n+s}{n} x^n = {}_2F_1(\tfrac{1}{2}(s+1), \tfrac{1}{2}(s+2); s+1, 4x)$$

$$= \frac{2^r}{(\sqrt{1-4x}+1)^r\sqrt{1-4x}}, \quad (38)$$

where ${}_2F_1(a, b; c; z)$ is a HYPERGEOMETRIC FUNCTION (Abramowitz and Stegun 1972, p. 555; Graham *et al.* 1994, p. 203).

For NONNEGATIVE INTEGERS n and r with $r \leq n+1$,

$$\sum_{k=0}^{n} \frac{(-1)^k}{k+1} \binom{n}{k} \left[\sum_{j=0}^{r-1} (-1)^j \binom{n}{j} (r-j)^{n-k} \right.$$

$$\left. + \sum_{j=0}^{n-r} (-1)^j \binom{n}{j} (n+1-r-j)^{n-k} \right] = n!. \quad (39)$$

Taking $n = 2r-1$ gives

$$\sum_{k=0}^{n} \frac{(-1)^k}{K-1} \binom{n}{k} \sum_{j=0}^{r-1} \binom{n}{j} (r-j)^{n-k} = \tfrac{1}{2}n!. \quad (40)$$

Other identities are

$$\sum_{k=0}^{n} \binom{n+k}{k} [x^{n+1}(1-x)^k + (1-x)^{n+1}x^k] = 1 \quad (41)$$

(Gosper 1972) and

$$\sum_i \binom{n_i}{2} + \sum_{i>j} n_i n_j = \binom{n}{2}, \quad (42)$$

where

$$n \equiv \sum_i n_i. \quad (43)$$

The latter is the umbral analog of the multinomial theorem for n^2

$$\frac{(a+b+c)^2}{2} = \frac{a^2}{2} + \frac{b^2}{2} + \frac{c^2}{2} + ab + ac + bc \quad (44)$$

using the lower-factorial polynomial $(n)_2 = n(n-1)/2$, giving

$$\binom{a+b+c}{2} = \binom{a}{2} + \binom{b}{2} + \binom{c}{2} + ab + ac + bc. \quad (45)$$

The identity holds true not only for $(n)_2$ and $n^2/2$, but also for any quadratic polynomial OF THE FORM $n(n+a)/2$ (Dubuque).

Binomial Theorem

The theorem that, for POSITIVE INTEGERS n,

$$(x+a)^n = \sum_{k=0}^{n} \frac{n!}{k!(n-k)!} x^k a^{n-k} = \sum_{k=0}^{n} \binom{n}{k} x^k a^{n-k},$$

the so-called BINOMIAL SERIES, where $\binom{n}{k}$ are BINOMIAL COEFFICIENTS. The theorem was known for the case $n = 2$ by Euclid around 300 BC, and stated in its modern form by Pascal in a posthumous pamphlet published in 1665. Newton (1676) showed that a similar formula (with INFINITE upper limit) holds for NEGATIVE INTEGERS n,

$$(x+a)^{-n} = \sum_{k=0}^{\infty} \binom{-n}{k} x^k a^{-n-k},$$

the so-called NEGATIVE BINOMIAL SERIES, which converges for $|x| > |a|$.

Binomial Transform

The binomial transform takes the sequence $a_0, a_1, a_2, \ldots$ to the sequence $b_0, b_1, b_2, \ldots$ via the transformation

$$b_n = \sum_{k=0}^{n} (-1)^{n-k} \binom{n}{k} a_k.$$

The inverse transform is

$$a_n = \sum_{k=0}^{n} \binom{n}{k} b_k.$$

(Sloane and Plouffe 1995, pp. 13 and 22). The inverse binomial transform of $b_n = 1$ for prime n and $b_n = 0$ for composite n is 0, 1, 3, 6, 11, 20, 37, 70, ... (Sloane's A052467). The inverse binomial transform of $b_n = 1$ for even n and $b_n = 0$ for odd n is 0, 1, 2, 4, 8, 16, 32, 64, ... (Sloane's A000079). Similarly, the inverse binomial transform of $b_n = 1$ for odd n and $b_n = 0$ for even n is 1, 2, 4, 8, 16, 32, 64, ... (Sloane's A000079). The inverse binomial transform of the BELL NUMBERS 1, 1, 2, 5, 15, 52, 203, ... (Sloane's A000110) is a shifted version of the same numbers: 1, 2, 5, 15, 52, 203, ... (Bernstein and Sloane 1995, Sloane and Plouffe 1995, p. 22).

The CENTRAL and RAW MOMENTS of statistical distributions are also related by the binomial transform.

Binormal Developable

A RULED SURFACE M is said to be a binormal developable of a curve $\mathbf{y}$ if M can be parameterized by $\mathbf{x}(u, v) = \mathbf{y}(u) + v\hat{\mathbf{B}}(u)$, where $\mathbf{B}$ is the BINORMAL VECTOR.

See also NORMAL DEVELOPABLE, TANGENT DEVELOPABLE

References

Gray, A. "Developables." §17.6 in *Modern Differential Geometry of Curves and Surfaces with Mathematica.* Boca Raton, FL: CRC Press, pp. 352–54, 1993.

Binormal Vector

$$\tilde{\mathbf{B}} \equiv \hat{\mathbf{T}} \times \hat{\mathbf{N}} \tag{1}$$

$$= \frac{\mathbf{r}' \times \mathbf{r}''}{|\mathbf{r}' \times \mathbf{r}''|}, \tag{2}$$

where the unit TANGENT VECTOR $\mathbf{T}$ and unit "principal" NORMAL VECTOR $\mathbf{N}$ are defined by

$$\hat{\mathbf{T}} \equiv \frac{\mathbf{r}'(s)}{|\hat{\mathbf{r}}(s)|} \tag{3}$$

$$\hat{\mathbf{N}} \equiv \frac{\mathbf{r}''(s)}{|\mathbf{r}''(s)|} \tag{4}$$

Here, $\mathbf{r}$ is the RADIUS VECTOR, s is the ARC LENGTH, τ is the TORSION, and κ is the CURVATURE. The binormal vector satisfies the remarkable identity

$$[\dot{\mathbf{B}}, \ddot{\mathbf{B}}, \dddot{\mathbf{B}}] = \tau^5 \frac{d}{ds}\left(\frac{\kappa}{\tau}\right). \tag{5}$$

Bin-Packing Problem

The problem of packing a set of items into a number of bins such that the total weight, volume, etc. does not exceed some maximum value. A simple algorithm (the first-fit algorithm) takes items in the order they come an places them in the first bin in which they fit. In 1973, J. Ullman proved that this algorithm can differ from an optimal packing by as much at 70% (Hoffman 1998, p. 171). An alternative strategy first orders the items from largest to smallest, then places them sequentially in the first bin in which they fit. In 1973, D. Johnson showed that this strategy is never suboptimal by more than 22%, and furthermore that *no* efficient bin-packing algorithm can be guaranteed to do better than 22% (Hoffman 1998, p. 172).

There exist arrangements of items such that applying the packing algorithm after *removing* an item results in *one more* bin being required than the number obtained if the item is *included* (Hoffman 1998, pp. 172–73).

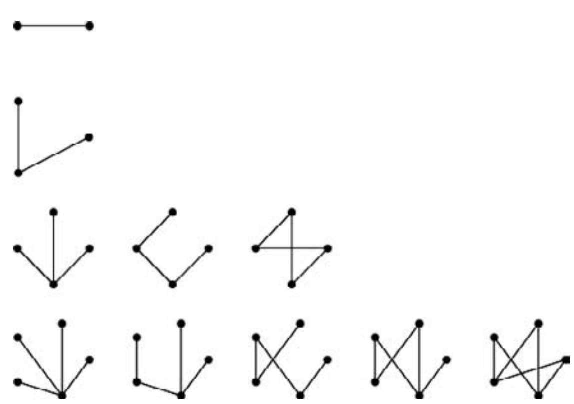
Biotic Potential



LOGISTIC EQUATION

Bipartite Graph

A set of VERTICES decomposed into two disjoint sets such that no two VERTICES within the same set are adjacent. A bigraph is a special case of a k-PARTITE GRAPH with $k = 2$. Bipartite graphs are equivalent to two-colorable graphs, and a graph is bipartite IFF all its cycles are of even length (Skiena 1990, p. 213). The numbers of bipartite graphs on $n = 1, 2, \ldots$ nodes are 1, 2, 3, 7, 13, 35, 88, 303, ... (Sloane's A033995). A graph can be tested for bipartiteness using `BipartiteQ[g]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).

The numbers of CONNECTED bipartite graphs on $n = 1, 2 \ldots$ nodes are 1, 1, 1, 3, 5, 17, 44, 182, ... (Sloane's A005142).

All TREES are bipartite (Skiena 1990, p. 213).

Biplanar Double Point

ISOLATED SINGULARITY

Bipolar Coordinates

Bipolar coordinates are a 2-D system of coordinates. There are two commonly defined types of bipolar coordinates, the first of which is defined by

$$x = \frac{a \sinh v}{\cosh v - \cos u} \tag{1}$$

$$y = \frac{a \sin u}{\cosh v - \cos u}, \tag{2}$$

where $u \in [0, 2\pi)$, $v \in (-\infty, \infty)$. The following identities show that curves of constant u and v are CIRCLES in xy-space.

$$x^2 + (y - a \cot u)^2 = a^2 \csc^2 u \tag{3}$$

$$(x - a \coth v)^2 + y^2 = a^2 \operatorname{csch}^2 v. \tag{4}$$

The SCALE FACTORS are

$$h_u = \frac{a}{\cosh v - \cos u} \tag{5}$$

$$h_v = \frac{a}{\cosh v - \cos u} \tag{6}$$

The LAPLACIAN is

$$\nabla^2 = \frac{(\cosh v - \cos u)^2}{a^2} \left(\frac{\partial^2}{\partial u^2} + \frac{\partial^2}{\partial v^2} \right). \tag{7}$$

LAPLACE'S EQUATION is separable.

Two-center bipolar coordinates are two coordinates giving the distances from two fixed centers r_1 and r_2, sometimes denoted r and r'. For two-center bipolar coordinates with centers at $(\pm c, 0)$,

$$r_1^2 = (x + c)^2 + y^2 \tag{8}$$

$$r_2^2 = (x - c)^2 + y^2. \tag{9}$$

Combining (8) and (9) gives

$$r_1^2 - r_2^2 = 4cx. \tag{10}$$

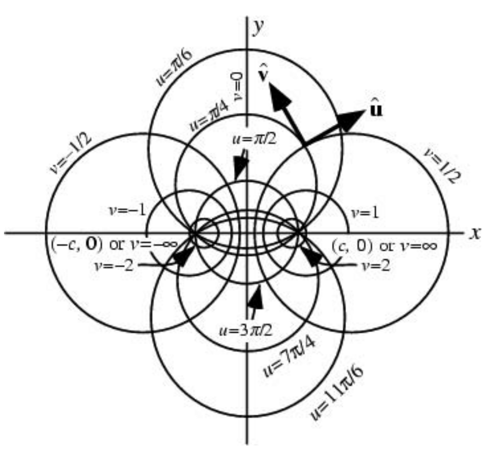
Solving for CARTESIAN COORDINATES x and y gives

$$x = \frac{r_1^2 - r_2^2}{4c} \tag{11}$$

$$y = \pm \frac{1}{4c} \sqrt{16c^2 r_1^2 - (r_1^2 - r_2^2 + 4c^2)^2}. \tag{12}$$

Solving for POLAR COORDINATES gives

$$r = \sqrt{\frac{r_1^2 + r_2^2 - 2c^2}{2}} \tag{13}$$



$$\theta = \tan^{-1}\left[\frac{\sqrt{r_2^4 - 2(4c^2 + r_1^2)r_2^2 - (4c^2 - r_1^2)^2}}{r_1^2 - r_2^2}\right]. \tag{14}$$

Bipolar Cylindrical Coordinates

A set of CURVILINEAR COORDINATES defined by

$$x = \frac{a \sinh v}{\cosh v - \cos u} \tag{1}$$

$$y = \frac{a \sin u}{\cosh v - \cos u} \tag{2}$$

$$z = z, \tag{3}$$

where $u \in [0, 2\pi)$, $v \in (-\infty, \infty)$, and $z \in (-\infty, \infty)$. There are several notational conventions, and whereas (u, v, z) is used in this work, Arfken (1970) prefers (η, ξ, z). The following identities show that curves of constant u and v are CIRCLES in xy-space.

$$x^2 + (y - a \cot u)^2 = a^2 \csc^2 u \tag{4}$$

$$(x - a \coth v)^2 + y^2 = a^2 \operatorname{csch}^2 v. \tag{5}$$

The SCALE FACTORS are

$$h_u = \frac{a}{\cosh v - \cos u} \tag{6}$$

$$h_v = \frac{a}{\cosh v - \cos u} \tag{7}$$

$$h_z = 1. \tag{8}$$

The LAPLACIAN is

$$\nabla^2 = \frac{(\cosh v - \cos u)^2}{a^2}\left(\frac{\partial^2}{\partial u^2} + \frac{\partial^2}{\partial v^2}\right) + \frac{\partial^2}{\partial z^2}. \tag{9}$$

LAPLACE'S EQUATION is not separable in BIPOLAR CYLINDRICAL COORDINATES, but it is in 2-D BIPOLAR COORDINATES.

DIPYRAMID

Biquadratefree

A number is said to be biquadratefree (or quarticfree) if its PRIME FACTORIZATION contains no quadrupled factors. All PRIMES and PRIME POWERS p^n with $n \leq 3$ are therefore trivially biquadratefree. The biquadratefree numbers are 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 17, ... (Sloane's A046100). The biquadrateful numbers (i.e., those that contain at least one biquadrate) are 16, 32, 48, 64, 80, 81, 96, ... (Sloane's A046101). The number of biquadratefree numbers less than 10, 100, 1000, ... are 10, 93, 925, 9240, 92395, 923939, ..., and their asymptotic density is $1/\zeta(4) = 90/\pi^4 \approx 0.923938$, where $\zeta(n)$ is the RIEMANN ZETA FUNCTION.

Biquadratic Equation

QUARTIC EQUATION

Biquadratic Number

A biquadratic number is a fourth POWER, n^4. The first few biquadratic numbers are 1, 16, 81, 256, 625, ... (Sloane's A000583). The minimum number of biquadratic numbers needed to represent the numbers 1, 2, 3, ... are 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 1, 2, 3, 4, 5, ... (Sloane's A002377), and the number of distinct ways to represent the numbers 1, 2, 3, ... in terms of biquadratic numbers are 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 2, 2, 2, 2, 2, ... A brute-force algorithm for enumerating the biquadratic permutations of n is repeated application of the GREEDY ALGORITHM.

Every POSITIVE integer is expressible as a SUM of (at most) $g(4) = 19$ biquadratic numbers (WARING'S PROBLEM). Davenport (1939) showed that $G(4) = 16$, meaning that all sufficiently large integers require only 16 biquadratic numbers. It is also known that every integer is a sum of at most 10 signed biquadrates ($eg(4) \leq 10$; although it is not known if 10 can be reduced to 9). The following table gives the first few numbers which require 1, 2, 3, ..., 19 biquadratic numbers to represent them as a sum, with the sequences for 17, 18, and 19 being finite.

#	Sloane	Numbers
1	Sloane's A000290	1, 16, 81, 256, 625, 1296, 2401, 4096, ...
2	Sloane's A003336	2, 17, 32, 82, 97, 162, 257, 272, ...
3	Sloane's A003337	3, 18, 33, 48, 83, 98, 113, 163, ...
4	Sloane's A003338	4, 19, 34, 49, 64, 84, 99, 114, 129, ...
5	Sloane's A003339	5, 20, 35, 50, 65, 80, 85, 100, 115, ...
6	Sloane's A003340	6, 21, 36, 51, 66, 86, 96, 101, 116, ...
7	Sloane's A003341	7, 22, 37, 52, 67, 87, 102, 112, 117, ...
8	Sloane's A003342	8, 23, 38, 53, 68, 88, 103, 118, 128, ...
9	Sloane's A003343	9, 24, 39, 54, 69, 89, 104, 119, 134, ...
10	Sloane's A003344	10, 25, 40, 55, 70, 90, 105, 120, 135, ...
11	Sloane's A003345	11, 26, 41, 56, 71, 91, 106, 121, 136, ...
12	Sloane's A003346	12, 27, 42, 57, 72, 92, 107, 122, 137, ...
13	Sloane's A046044	13, 28, 43, 58, 73, 93, 108, 123, 138, ...
14	Sloane's A046045	14, 29, 44, 59, 74, 94, 109, 124, 139, ...
15	Sloane's A046046	15, 30, 45, 60, 75, 95, 110, 125, 140, ...
16	Sloane's A046047	31, 46, 61, 76, 111, 126, 141, 156, ...
17	Sloane's A046048	47, 62, 77, 127, 142, 157, 207, 222, ...
18	Sloane's A046049	63, 78, 143, 158, 223, 238, 303, 318, ...
19	Sloane's A046050	79, 159, 239, 319, 399

The following table gives the numbers which can be represented in n different ways as a sum of k biquadrates.

k	n	Sloane	Numbers
1	1	Sloane's A000290	1, 16, 81, 256, 625, 1296, 2401, 4096, ...
2	2	Sloane's A018786	635318657, 3262811042, 8657437697, ...

The numbers 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 18, 19, 20, 21, ... (Sloane's A046039) cannot be represented using distinct biquadrates.

Biquadratic Reciprocity Theorem

Gauss stated the reciprocity theorem for the case $n=4$

$$x^4 \equiv q \pmod p \quad (1)$$

can be solved using the GAUSSIAN INTEGERS as

$$\left(\frac{\pi}{\sigma}\right)_4 \left(\frac{\sigma}{\pi}\right)_4 = (-1)^{[(N(\pi)-1)/4][(N(\sigma)-1)/4]}. \quad (2)$$

Here, π and σ are distinct GAUSSIAN INTEGER PRIMES, and

$$N(a+bi) = \sqrt{a^2+b^2} \quad (3)$$

is the norm. The symbol $\left(\frac{\alpha}{\pi}\right)$ means

$$\left(\frac{\alpha}{\pi}\right)_4 = \begin{cases} 1 & \text{if } x^4 \equiv \alpha \pmod \pi \text{ is solvable} \\ -1,\ i,\ \text{or}\ -i & \text{otherwise} \end{cases} \quad (4)$$

where "solvable" means solvable in terms of GAUSSIAN INTEGERS.

2 is a quartic residue (mod p) IFF there are integers x, y such that

$$x^2 + 64y^2 = p. \quad (5)$$

This is a generalization of the GENUS THEOREM.

Biquadratic Residue

If there is an INTEGER x such that

$$x^4 \equiv q \pmod p, \quad (1)$$

then q is said to be a biquadratic residue (mod p). If not, q is said to be a biquadratic nonresidue (mod p).

Birch Conjecture

SWINNERTON-DYER CONJECTURE

Birch-Swinnerton-Dyer Conjecture

SWINNERTON-DYER CONJECTURE

Birkhoff's Ergodic Theorem

Let T be an ergodic ENDOMORPHISM of the PROBABILITY SPACE X and let $f: X \to \mathbb{R}$ be a real-valued MEASURABLE FUNCTION. Then for ALMOST EVERY $x \in X$, we have

$$\frac{1}{n}\sum_{j=1}^{n} f \circ T^j(x) \to \int f\, dm \quad (1)$$

as $n \to \infty$. To illustrate this, take f to be the characteristic function of some SUBSET A of X so that

$$f(x) = \begin{cases} 1 & \text{if } x \in A \\ 0 & \text{if } x \notin A. \end{cases} \quad (2)$$

The left-hand side of (1) just says how often the orbit of x (that is, the points x, Tx, T^2x, ...) lies in A, and the right-hand side is just the MEASURE of A. Thus, for an ergodic ENDOMORPHISM, "space-averages = time-averages almost everywhere." Moreover, if T is continuous and uniquely ergodic with BOREL PROBABILITY MEASURE m and f is continuous, then we can replace the ALMOST EVERYWHERE convergence in (1) with "everywhere."

Birthday Attack

Birthday attacks are a class of brute-force techniques used in an attempt to solve a class of CRYPTOGRAPHIC HASH FUNCTION problems. These methods take advantage of functions which, when supplied with a random input, return one of k equally likely values. By repeatedly evaluating the function for different inputs, the same output is expected to be obtained after about $1.2\sqrt{k}$ evaluations.

See also BIRTHDAY PROBLEM, CRYPTOGRAPHIC HASH FUNCTION

Birthday Problem

Consider the probability $Q_1(n, d)$ that *no two people* out of a group of n will have matching birthdays out of d equally possible birthdays. Start with an arbitrary person's birthday, then note that the probability that the second person's birthday is different is $(d-1)/d$, that the third person's birthday is different from the first two is $[(d-1)/d][(d-2)/d]$, and so on, up through the nth person. Explicitly,

$$Q_1(n, d) = \frac{d-1}{d}\frac{d-2}{d}\cdots\frac{d-(n-1)}{d} = \frac{(d-1)(d-2)\cdots[d-(n-1)]}{d^{n-1}}. \quad (1)$$

But this can be written in terms of FACTORIALS as

$$Q_1(n, d) = \frac{d!}{(d-n)!d^n}, \quad (2)$$

so the probability $P_2(n, 365)$ that two people out of a group of n *do have the same birthday* is therefore

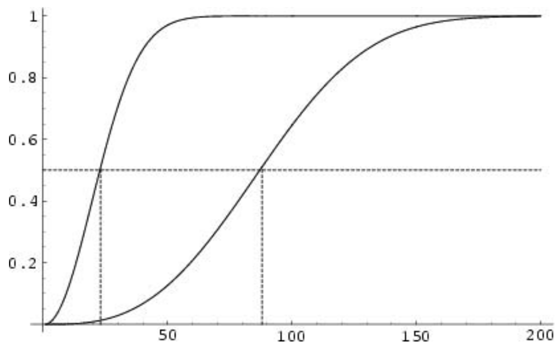
$$P_2(n, d) = 1 - Q_1(n, d) = 1 - \frac{d!}{(d-n)!d^n}. \quad (3)$$

If 365-day years have been assumed, i.e., the existence of leap days is ignored, then the number of people needed for there to be at least a 50% chance that two share birthdays is the smallest n such that $P_2(n, 365) \geq 1/2$. This is given by $n = 23$, since

$$P_2(23, 365) = \frac{38093904702297390785243708291056390518886454060947}{75091883268515350125426207425223147563269805908203} \approx 0.507297. \quad (4)$$

The number n of people needed to obtain $P_2(n, d) \geq 1/2$ for $d = 1, 2, \ldots$, are 2, 2, 3, 3, 3, 4, 4, 4, 4, 5, ... (Sloane's A033810).

The probability $P_2(n, d)$ can be estimated as



$$P_2(n, d) \approx 1 - e^{-n(n-1)/2d} \quad (5)$$

$$\approx 1 - \left(1 - \frac{n}{2d}\right)^{n-1}, \quad (6)$$

where the latter has error

$$\epsilon < \frac{n^3}{6(d-n+1)^2} \tag{7}$$

(Sayrafiezadeh 1994).

In general, let $Q_i(n, d)$ denote the probability that a birthday is shared by exactly i (and no more) people out of a group of n people. Then the probability that a birthday is shared by k *or more* people is given by

$$P_k(n, d) = 1 - \sum_{i=1}^{k-1} Q_i(n, d). \tag{8}$$

Q_2 can be computed explicitly as

$$\begin{aligned} Q_2(n, d) &= \frac{n!}{d^n} \sum_{i=2}^{\lfloor n/2 \rfloor} \frac{1}{2^i} \binom{d}{i} \binom{d-i}{n-2i} \\ &= \frac{n!}{d^n} \sum_{i=1}^{\lfloor n/2 \rfloor} \frac{d!}{2^i i!(n-2i)!(d-n+i)!} \\ &= \frac{(-1)^n}{d^n} \left[2^{-n/2} \Gamma(1+n) P_n^{(-d)}(\tfrac{1}{2}\sqrt{2}) \right. \\ &\quad \left. - \frac{\Gamma(1+d)}{\Gamma(1+d-n)} \right], \end{aligned} \tag{9}$$

where $\binom{n}{m}$ is a BINOMIAL COEFFICIENT, $\Gamma(n)$ is a GAMMA FUNCTION, and $P_n^{(\lambda)}(x)$ is an ULTRASPHERICAL POLYNOMIAL. This gives the explicit formula for $P_3(n, d)$ as

$$\begin{aligned} P_3(n, d) &= 1 - Q_1(n, d) - Q_2(n, d) \\ &= 1 + \frac{(-1)^{n+1} \Gamma(n+1) P_n^{(-d)}(2^{-1/2})}{2^{n/2} d^n}. \end{aligned} \tag{10}$$

$Q_3(n, d)$ cannot be computed in entirely closed form, but a partially reduced form is

$$\begin{aligned} Q_3(n, d) &= \frac{\Gamma(d+1)}{d^n} \left[\frac{(-1)^n F(\frac{9}{8}) - F(-\frac{9}{8})}{\Gamma(d-n+1)} + (-1)^n \Gamma \right. \\ &\quad \left. \times (1+n) \sum_{i=1}^{\lfloor n/3 \rfloor} \frac{(-3)^{-i} 2^{(i-n)/2} P_{n-3i}^{(i-d)}(\frac{1}{2}\sqrt{2})}{\Gamma(d-i+1)\Gamma(i+1)} \right], \end{aligned} \tag{11}$$

where

$$F = F(n, d, a) \equiv 1 - {}_3F_2 \left[\begin{matrix} \frac{1}{3}(1-n), \frac{1}{3}(2-n), -\frac{1}{3} \\ \frac{1}{2}(d-n+1), \frac{1}{2}(d-n+2) \end{matrix}; a \right] \tag{12}$$

and ${}_3F_2(a, b, c; d, e; z)$ is a GENERALIZED HYPERGEOMETRIC FUNCTION.

In general, $Q_k(n, d)$ can be computed using the RECURRENCE RELATION

$$\begin{aligned} Q_k(n, d) &= \sum_{i=1}^{\lfloor n/k \rfloor} \left[\frac{n! d!}{d^{ik} i! (k!)^i (n-ik)!(d-i)!} \right. \\ &\quad \left. \times \sum_{j=1}^{k-1} Q_j(n-k, d-i) \frac{(d-i)^{n-ik}}{d^{n-ik}} \right] \end{aligned} \tag{13}$$

(Finch). However, the time to compute this recursive function grows exponentially with k and so rapidly becomes unwieldy. The minimal number of people to give a 50% probability of having at least n coincident birthdays is 1, 23, 88, 187, 313, 460, 623, 798, 985, 1181, 1385, 1596, 1813, ... (Sloane's A014088; Diaconis and Mosteller 1989).

A good approximation to the number of people n such that $p = P_k(n, d)$ is some given value can be given by solving the equation

$$ne^{-n/(dk)} = \left[d^{k-1} k! \ln\left(\frac{1}{1-p} \right) \left(1 - \frac{n}{d(k+1)} \right) \right]^{1/k} \tag{14}$$

for n and taking $\lceil n \rceil$, where $\lceil n \rceil$ is the CEILING FUNCTION (Diaconis and Mosteller 1989). For $p = 0.5$ and $k = 1, 2, 3, \ldots$, this formula gives $n = 1, 23, 88, 187, 313, 459, 622, 797, 983, 1179, 1382, 1592, 1809, \ldots$ (Sloane's A050255), which differ from the true values by from 0 to 4. A much simpler but also poorer approximation for n such that $p = 0.5$ for $k < 20$ is given by

$$n = 47(k-1.5)^{3/2} \tag{15}$$

(Diaconis and Mosteller 1989), which gives 86, 185, 307, 448, 606, 778, 965, 1164, 1376, 1599, 1832, ... for $k = 3, 4, \ldots$ (Sloane's A050256).

The "almost" birthday problem, which asks the number of people needed such that two have a birthday within a day of each other, was considered by Abramson and Moser (1970), who showed that 14 people suffice. An approximation for the minimum number of people needed to get a 50–0 chance that two have a match within k days out of d possible is given by

$$n(k, d) = 1.2 \sqrt{\frac{d}{2k+1}} \tag{16}$$

(Sevast'yanov 1972, Diaconis and Mosteller 1989).

Bisected Perimeter Point

NAGEL POINT

Bisection Procedure

A simple procedure for iteratively converging on a solution which is known to lie inside some interval $[a, b]$. Let a_π and b_n be the endpoints at the nth iteration and r_n be the nth approximate solution. Then, the number of iterations required to obtain an error smaller than ϵ is found as follows.

$$b_n - a_n = \frac{1}{2^{n-1}}(b-a) \tag{1}$$

$$r_n \equiv \tfrac{1}{2}(a_n + b_n) \tag{2}$$

$$|r_n - r| \leq \tfrac{1}{2}(b_n - a_n) = 2^{-n}(b-a) < \epsilon \tag{3}$$

$$-n \ln 2 < \ln \epsilon - \ln(b-a), \tag{4}$$

so

$$n > \frac{\ln(b-a) - \ln \epsilon}{\ln 2}. \tag{5}$$

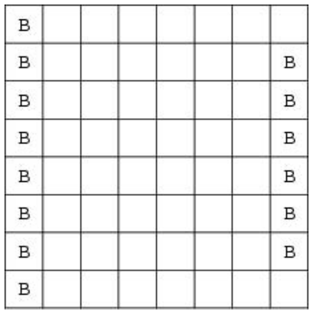
Bisector

Bisection is the division of a given curve or figure into two equal parts (halves).

See also ANGLE BISECTOR, BISECTION PROCEDURE, EXTERIOR ANGLE BISECTOR, HALF, HEMISPHERE, LINE BISECTOR, PERPENDICULAR BISECTOR, TRISECTION

Bishop's Inequality



Let $V(r)$ be the volume of a BALL of radius r in a complete n-D RIEMANNIAN MANIFOLD with RICCI CURVATURE $\geq (n-1)\kappa$. Then $V(r) \geq V_\kappa(r)$, where V_κ is the volume of a BALL in a space having constant SECTIONAL CURVATURE. In addition, if equality holds for some BALL, then this BALL is ISOMETRIC to the BALL of radius r in the space of constant SECTIONAL CURVATURE κ.

See also BALL, ISOMETRY

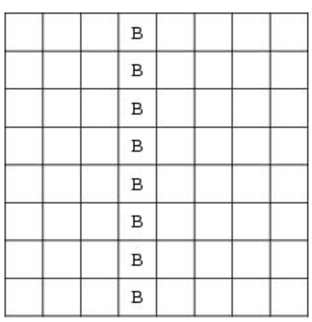
Bishops Problem



Find the maximum number of bishops $B(n)$ which can be placed on an $n \times n$ CHESSBOARD such that no two attack each other. The answer is $2n-2$ (Dudeney 1970, Madachy 1979), giving the sequence 2, 4, 6, 8, ... (the EVEN NUMBERS) for $n = 2, 3, \ldots$. One maximal solution for $n = 8$ is illustrated above. The number of distinct maximal arrangements of bishops for $n = 1, 2, \ldots$ are 1, 4, 26, 260, 3368, ... (Sloane's A002465). The number of rotationally and reflectively distinct solutions on an $n \times n$ board for $n \geq 2$ is

$$B(n) = \begin{cases} 2^{(n-4)/2}[2^{(n-2)/2}+1] & \text{for } n \text{ even} \\ 2^{(n-3)/2}[2^{(n-3)/2}+1] & \text{for } n \text{ odd} \end{cases}$$

(Dudeney 1970, p. 96; Madachy 1979, p. 45; Pickover 1995). An equivalent formula is

$$B(n) = 2^{n-3} + 2^{\lfloor (n-1)/2 \rfloor - 1},$$

where $\lfloor n \rfloor$ is the FLOOR FUNCTION, giving the sequence for $n = 1, 2, \ldots$ as 1, 1, 2, 3, 6, 10, 20, 36, ... (Sloane's A005418).

The minimum number of bishops needed to occupy or attack all squares on an $n \times n$ CHESSBOARD is n, arranged as illustrated above.

Bislit Cube

The 8-VERTEX graph consisting of a CUBE in which two opposite faces have DIAGONALS oriented PERPENDICULAR to each other.

See also BIDIAKIS CUBE, CUBE, CUBICAL GRAPH

Bispherical Coordinates

A system of CURVILINEAR COORDINATES variously denoted (ξ, η, ϕ) (Arfken 1970) or (θ, η, ψ) (Moon and Spencer 1988). Using the notation of Arfken, the bispherical coordinates are defined by

$$x = \frac{a \sin \xi \cos \phi}{\cosh \eta - \cos \xi} \tag{1}$$

$$y = \frac{a \sin \xi \sin \phi}{\cosh \eta - \cos \xi} \tag{2}$$

$$z = \frac{a \sinh \eta}{\cosh \eta - \cos \xi}. \tag{3}$$

Surfaces of constant η are given by the spheres

$$x^2+y^2+(z-a\coth\eta)^2=\frac{a^2}{\sinh^2\eta}, \tag{4}$$

surfaces of constant ξ by the APPLES ($\xi<\pi/2$) or LEMONS ($\xi>\pi/2$)

$$x^2+y^2+z^2-2a\sqrt{x^2+y^2}\cot\xi=a^2, \tag{5}$$

and surface of constant ψ by the half-planes

$$\tan\phi=y/x. \tag{6}$$

The SCALE FACTORS are

$$h_\xi=\frac{a}{\cos\eta-\cos\xi} \tag{7}$$

$$h_\eta=\frac{a}{\cosh\eta-\cos\xi} \tag{8}$$

$$h_\phi=\frac{a\sin\xi}{\cosh\eta-\cos\xi}. \tag{9}$$

The LAPLACIAN is given by

$$\nabla^2 f=\frac{(\cosh\eta-\cos\xi)^2}{a^2\sin\xi}\times\left\{\sin\xi\frac{\partial}{\partial\eta}\left(\frac{1}{\cosh\eta-\cos\xi}\frac{\partial f}{\partial\eta}\right)+\frac{\partial}{\partial\xi}\left(\frac{\sin\xi}{\cosh\eta-\cos\xi}\frac{\partial f}{\partial\xi}\right)\right\}+\frac{(\cosh\eta-\cos\xi)^2}{a^2\sin^2\xi}\frac{\partial^2 f}{\partial\phi^2}.$$

In bispherical coordinates, LAPLACE'S EQUATION is separable (Moon and Spencer 1988), but the HELMHOLTZ DIFFERENTIAL EQUATION is not.

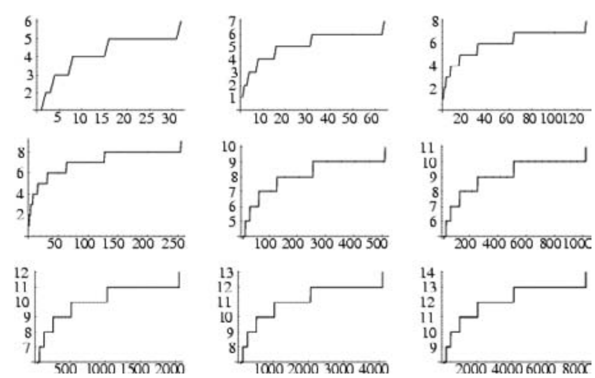
Muir, T. *A Treatise on the Theory of Determinants.* New York: Dover, 1960.

Bit Complexity



The number of single operations (of ADDITION, SUBTRACTION, and MULTIPLICATION) required to complete an algorithm.

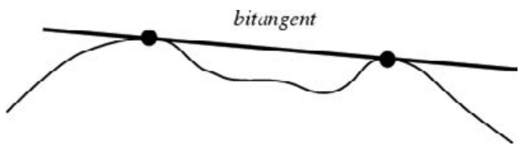
See also STRASSEN FORMULAS

References

Borodin, A. and Munro, I. *The Computational Complexity of Algebraic and Numeric Problems.* New York: American Elsevier, 1975.

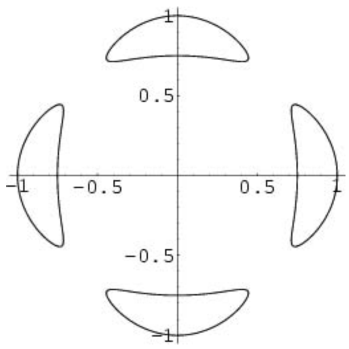
Bit Length

The number of binary bits necessary to represent a number, given explicitly by



$$BL(n)=\lceil \lg n\rceil,$$

where $\lceil x\rceil$ is the CEILING FUNCTION and $\lg n$ is LG, the LOGARITHM to base 2. For $n=0$, 1, 2, ..., the first few values are 0, 1, 2, 2, 3, 3, 3, 3, 4, 4, ... (Sloane's A036377). The function is given by the *Mathematica* 4.0 function `BitLength[n]` in the `Developer` context.



References

Bitangent

A LINE which is TANGENT to a curve at two distinct points.

There exist plane QUARTIC CURVES

$$\sum_{i+j\leq 4} a_{ij}x^i y^j = 0$$

that have 28 real bitangents (Shioda 1995, Trott 1997), for example

$$12^2(x^4+y^4)-15^2(x^2+y^2)+350x^2y^2+81=0$$

(Trott 1997), illustrated above.

Bitwin Chain

A bitwin chain of length one consists of two pairs of TWIN PRIMES with the property that they are related by being of the form:

$$(n-1,\ n+1) \text{ and } (2n-1,\ 2n+1).$$

In general a chain of length i consists of $i+1$ pairs of TWIN PRIMES,

$$(n-1,\ n+1),\ (2n-1,\ 2n+1),\ \ldots,\ (2^i\cdot n-1,\ 2^i\cdot n+1).$$

Bitwin chains can also be viewed as consisting of two related CUNNINGHAM CHAINS of the first and second kinds,

$$(n-1,\ 2n-1,\ 4n-1,\ \ldots) \text{ and }$$

$$(n+1,\ 2n+1,\ 4n+1,\ \ldots).$$

P. Jobling (1999) found the largest known chain of length six,

$$337190719854678690\cdot 2^n\pm 1,$$

where $n=0$ to 6.

See also CUNNINGHAM CHAIN, TWIN PRIMES

GAUSSIAN BIVARIATE DISTRIBUTION

Bivector

An antisymmetric TENSOR of second RANK (a.k.a. 2-form).

$$\vec{X} = X_{ab}\omega^a \wedge \omega^b,$$

where $\wedge$ is the WEDGE PRODUCT (or OUTER PRODUCT).

See also TENSOR, VECTOR

Biweight

TUKEY'S BIWEIGHT

Björling Curve

Let $\boldsymbol{\alpha}(z),\ \gamma(z) : (a,\ b) \to \mathbb{R}^3$ be curves such that $\|\gamma\| = 1$ and $\boldsymbol{\alpha} \cdot \gamma = 0$, and suppose that $\boldsymbol{\alpha}$ and γ have holomorphic extensions $\boldsymbol{\alpha},\ \gamma : (a,\ b) \times (c,\ d) \to \mathbb{C}^3$ such that $\|\gamma\| = 1$ and $\boldsymbol{\alpha} \cdot \gamma = 0$ also for $z \in (a,\ b) \times (c,\ d)$. Fix $z_0 \in (a,\ b) \times (c,\ d)$. Then the Björling curve, defined by

$$B(z) = \boldsymbol{\alpha}(z) - i \int_{z_0}^{z} \gamma(z) \times \boldsymbol{\alpha}'(z)\, dz,$$

is a minimal curve (Gray 1997, p. 762).

Black Dot Illusion

In the above illustration, black dots appear to form and vanish at the intersections of the gray horizontal and vertical lines. When focusing attention on a single white dot, some gray dots nearby and some black dots a little further away also seem to appear. More black dots seem to appear as the eye is scanned across the image (as opposed to focusing on a single point). Strangely, the effect seems to be reduced, but not eliminated, when the head is cocked at a 45° angle. The effect seems to exist only at intermediate distances; if the eye is moved very close to or very far away from the figure, the phantom black dots do not appear.

Black Spleenwort Fern

BARNSLEY'S FERN

Blackboard Bold

DOUBLESTRUCK

Blackman Function

An APODIZATION FUNCTION given by

$$A(x) = 0.42 + 0.5 \cos\left(\frac{\pi x}{a}\right) + 0.08 \cos\left(\frac{2\pi x}{a}\right). \tag{1}$$

Its FULL WIDTH AT HALF MAXIMUM is $0.810957a$. The APPARATUS FUNCTION is

$$I(k) = \frac{a(0.84 - 0.36a^2k^2 - 2.17 \times 10^{-19}a^4k^4)\sin(2\pi ak)}{(1 - a^2k^2)(1 - 4a^2k^2)}. \tag{2}$$

The COEFFICIENTS are approximations in the general

expansion

$$A(x) = a_0 + 2\sum_{n=1}^{\infty} a_n \cos\left(\frac{n\pi x}{b}\right), \tag{3}$$

to

$$a_0 = \frac{3969}{9304} \approx 0.42659 \tag{4}$$

$$a_1 = \frac{1155}{4652} \approx 0.24828 \tag{5}$$

$$a_2 = \frac{715}{18608} \approx 0.38424, \tag{6}$$

which produce zeros of $I(k)$ at $ka = 7/4$ and $ka = 9/4$.

Black-Scholes Theory

The theory underlying financial derivatives which involves "stochastic calculus" and assumes an uncorrelated LOG NORMAL DISTRIBUTION of continuously varying prices. A simplified "binomial" version of the theory was subsequently developed by Sharpe *et al.* (1995) and Cox *et al.* (1979). It reproduces many results of the full-blown theory, and allows approximation of options for which analytic solutions are not known (Price 1996).

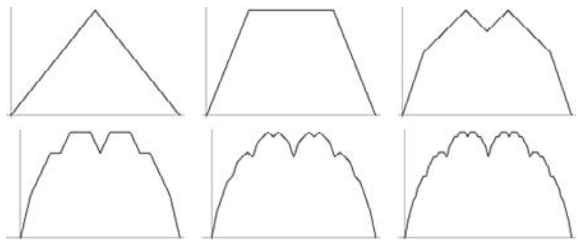
Blancmange Function



A CONTINUOUS FUNCTION which is nowhere DIFFERENTIABLE. The iterations towards the continuous function are BATRACHIONS resembling the HOFSTADTER-CONWAY \$10,000 SEQUENCE. The first six iterations are illustrated below. The dth iteration contains $N+1$ points, where $N = 2^d$, and can be obtained by setting $b(0) = b(N) = 0$, letting

$$b(m + 2^{n-1}) = 2^n + \tfrac{1}{2}[b(m) + b(m + 2^n)],$$

and looping over $n = d$ to 1 by steps of -1 and $m = 0$

to $N-1$ by steps of 2^n.

Peitgen and Saupe (1988) refer to this curve as the TAKAGI FRACTAL CURVE.

Blaschke Condition

If $\{a_j\} \subseteq D(0, 1)$ (with possible repetitions) satisfies

$$\sum_{j=1}^{\infty} (1 - |a_j|) \leq \infty,$$

where $D(0, 1)$ is the unit open disk, and no $a_j = 0$, then there is a bounded ANALYTIC FUNCTION on $D(0, 1)$ which has ZERO SET consisting precisely of the a_js, counted according to their MULTIPLICITIES. More specifically, the INFINITE PRODUCT

$$\prod_{j=1}^{\infty} -\frac{\bar{a}_j}{|a_j|} B_{a_j}(z),$$

where $B_{a_j}(z)$ is a BLASCHKE FACTOR and $\tilde{z}$ is the COMPLEX CONJUGATE, converges uniformly on compact subsets of $D(0, 1)$ to a bounded analytic function $B(z)$.

Blaschke Factor

If a is a point in the open UNIT DISK, then the Blaschke factor is defined by

$$B_a(z) = \frac{z - a}{1 - \bar{a}z},$$

where $\bar{a}$ is the COMPLEX CONJUGATE of a. Blaschke factors allow the manipulation of the zeros of a HOLOMORPHIC FUNCTION analogously to factors of $(z-a)$ for complex polynomials (Krantz 1999, p. 117).

Blasius Differential Equation

The third-order ORDINARY DIFFERENTIAL EQUATION

$$2y''' + yy'' = 0.$$

This equation arises in the theory of fluid boundary layers, and must be solved numerically (Rosenhead 1963; Schlichting 1979; Tritton 1989, p. 129). The velocity profile produced by this differential equation is known as the Blasius profile.

BLM/Ho Polynomial

A 1-variable unoriented KNOT POLYNOMIAL $Q(x)$. It satisfies

$$Q_{\text{unknot}} = 1 \tag{1}$$

and the SKEIN RELATIONSHIP

$$Q_{L_+} + Q_{L_-} = x(Q_{L_0} + Q_{L_\infty}). \tag{2}$$

It also satisfies

$$Q_{L_1 \# L_2} = Q_{L_1} Q_{L_2}, \tag{3}$$

where is the KNOT SUM and

$$Q_{L^*} = Q_L, \tag{4}$$

where L^* is the MIRROR IMAGE of L. The BLM/Ho polynomials of MUTANT KNOTS are also identical. Brandt *et al.* (1986) give a number of interesting properties. For any LINK L with ≥ 2 components, $Q_L - 1$ is divisible by $2(x-1)$. If L has c components, then the lowest POWER of x in $Q_L(x)$ is $1-c$, and

$$\lim_{x \to 0} x^{c-1} Q_L(x) = \lim_{(\ell,\ m) \to (1,\ 0)} (-m)^{c-1} P_L(\ell,\ m), \tag{5}$$

where P_L is the HOMFLY POLYNOMIAL. Also, the degree of Q_L is less than the CROSSING NUMBER of L. If L is a 2-BRIDGE KNOT, then

$$Q_L(z) = 2z^{-1} V_L(t) V_L(t^{-1} + 1 - 2z^{-1}), \tag{6}$$

where $z \equiv -t - t^{-1}$ (Kanenobu and Sumi 1993).

The POLYNOMIAL was subsequently extended to the 2-variable KAUFFMAN POLYNOMIAL F, which satisfies

$$Q(x) = F(1,\ x). \tag{7}$$

Brandt *et al.* (1986) give a listing of Q POLYNOMIALS for KNOTS up to 8 crossings and links up to 6 crossings.

Bloch Constant

N.B. A detailed online essay by S. Finch was the starting point for this entry. Let F be the set of COMPLEX ANALYTIC FUNCTIONS f defined on an open region containing the CLOSURE of the UNIT DISK $D = \{z : |z| < 1\}$ satisfying $f(0) = 0$ and $df/dz(0) = 1$. For each f in F, let $b(f)$ be the SUPREMUM of all numbers r such that there is a disk S in D on which f is ONE-TO-ONE and such that $f(S)$ contains a disk of radius r. In 1925, Bloch (Conway 1978) showed that $b(f) \geq 1/72$. Define Bloch's constant by

$$B \equiv \inf\{b(f) : f \in F\}.$$

Ahlfors and Grunsky (1937) derived

$$0.433012701\ldots = \tfrac{1}{4}\sqrt{3} \leq B < \frac{1}{\sqrt{1+\sqrt{3}}} \frac{\Gamma(\frac{1}{3})\Gamma(\frac{11}{12})}{\Gamma(\frac{1}{4})} < 0.4718617.$$

They also conjectured that the upper limit is actually the value of B,

$$\begin{aligned} B &= \frac{1}{\sqrt{1+\sqrt{3}}} \frac{\Gamma(\frac{1}{3})\Gamma(\frac{11}{12})}{\Gamma(\frac{1}{4})} \\ &= \sqrt{\pi}\, 2^{1/4} \frac{\Gamma(\frac{1}{3})}{\Gamma(\frac{1}{4})} \sqrt{\frac{\Gamma(\frac{11}{12})}{\Gamma(\frac{1}{12})}} \\ &= 0.4718617\ldots \end{aligned}$$

(Le Lionnais 1983).

Bloch-Landau Constant

LANDAU CONSTANT

Block

A maximal BICONNECTED SUBGRAPH of a given GRAPH G. In the illustration above, the blocks are $\{2,\ 5,\ 6\}$, $\{3,\ 4,\ 6,\ 7\}$, and $\{1,\ 7\}$.
If a graph G is biconnected, then G itself is called a block (Harary 1994, p. 26) or a BICONNECTED GRAPH (Skiena 1990, p. 175).

See also BICONNECTED GRAPH, BLOCK DESIGN, DIGIT BLOCK, SQUARE POLYOMINO

Block (Group Action)

A GROUP ACTION $G \times \Omega \to \Omega$ might preserve a special kind of PARTITION of Ω called a system of blocks. A block is a SUBSET Δ of Ω such that for any group element g either

1. g preserves Δ, i.e., $g\Delta = \Delta$, or
2. g translates everything in Δ out of Δ, i.e., $g\Delta \cap \Delta = \phi$.

For example, the GENERAL LINEAR GROUP $GL(2, \mathbb{R})$ acts on the plane minus the origin, $\mathbb{R}^2 - (0, 0)$. The lines $A = \{(at, bt)\}$ are blocks because either a line is mapped to itself, or to another line. Of course, the points on the line may be rescaled, so the lines in A are minimal blocks.

In fact, if two blocks intersect then their intersection is also a block. Hence, the minimal blocks form a PARTITION of Ω. It is important to avoid confusion with the notion of a block in a BLOCK DESIGN, which is different.

See also GROUP, PRIMITIVE (GROUP ACTION), STEINER SYSTEM

References

Dixon, J. and Mortimer, B. *Permutation Groups.* New York: Springer-Verlag, 1996.

Block (Set)

One of the disjoint SUBSETS making up a SET PARTITION. A block containing n elements is called an n-block. The partitioning of sets into blocks can be denoted using a RESTRICTED GROWTH STRING.

See also BLOCK DESIGN, RESTRICTED GROWTH STRING, SET PARTITION

Block Design

An incidence system (v, k, λ, r, b) in which a set X of v points is partitioned into a family A of b subsets (blocks) in such a way that any two points determine λ blocks with k points in each block, and each point is contained in r different blocks. It is also generally required that $k < v$, which is where the "incomplete" comes from in the formal term most often encountered for block designs, BALANCED INCOMPLETE BLOCK DESIGNS (BIBD). The five parameters are not independent, but satisfy the two relations

$$vr = bk \tag{1}$$

$$\lambda(v-1) = r(k-1). \tag{2}$$

A BIBD is therefore commonly written as simply (v, k, λ), since b and r are given in terms of v, k, and λ by

$$b = \frac{v(v-1)\lambda}{k(k-1)} \tag{3}$$

$$r = \frac{\lambda(v-1)}{k-1}. \tag{4}$$

A BIBD is called SYMMETRIC if $b = v$ (or, equivalently, $r = k$).

Writing $X = \{x_i\}_{i=1}^{v}$ and $A = \{A_j\}_{j=1}^{b,}$ then the INCIDENCE MATRIX of the BIBD is given by the $v \times b$ MATRIX $\mathbf{M}$ defined by

$$m_{ij} = \begin{cases} 1 & \text{if } x_i \in A \\ 0 & \text{otherwise.} \end{cases} \tag{5}$$

This matrix satisfies the equation

$$\mathsf{MM}^{\mathsf{T}} = (r - \lambda)\mathsf{I} + \lambda \mathsf{J}, \tag{6}$$

where I is a $v \times v$ IDENTITY MATRIX and J is the $v \times v$ UNIT MATRIX (Dinitz and Stinson 1992).

Examples of BIBDs are given in the following table.

Block Design	(v, k, λ)
AFFINE PLANE	$(n^{2,} n, 1)$
FANO PLANE	(7, 3, 1)
HADAMARD DESIGN	SYMMETRIC $(4n + 3, 2n + 1, n)$
PROJECTIVE PLANE	SYMMETRIC $(n^2 + n + 1, n + 1, 1)$
STEINER TRIPLE SYSTEM	$(v, 3, 1)$
UNITAL	$(q^3 + 1, q + 1, 1)$

Block Diagonal Matrix

A block diagonal matrix, also called a diagonal block matrix, is a SQUARE DIAGONAL MATRIX in which the diagonal elements are SQUARE MATRICES of any size (possibly even 1×1), and the off-diagonal elements are 0. A block diagonal matrix is therefore a BLOCK MATRIX in which the blocks off the diagonal are the ZERO MATRICES, and the diagonal matrices are SQUARE.

Block diagonal matrices can be constructed in *Mathematica* using the following code snippet.

```
<<LinearAlgebra`MatrixManipulation`
BlockDiagonal[a_List]:=
Module[{n=Length[a],lens=Length/@a,i,k,tmp},
  k=Outer[List,lens,lens];
tmp=Map[ZeroMatrix[#1[[1]],#1[[2]]]&,k,{2}];
  BlockMatrix@
ReplacePart[tmp,a,Table[{i,i},{i,Length[a]}],
  Table[{i},{i,Length[a]}]]]
```

See also BLOCK MATRIX, CAYLEY-HAMILTON THEOREM, DIAGONAL MATRIX, DIRECT SUM, JORDAN CANONICAL FORM, LINEAR TRANSFORMATION, MATRIX, MATRIX DIRECT SUM

Block Growth

Let $(x_0x_1x_2\ldots)$ be a sequence over a finite ALPHABET A (all the entries are elements of A). Define the block growth function $B(n)$ of a sequence to be the number of ADMISSIBLE words of length n. For example, in the sequence $aabaabaabaabaab\ldots$, the following words are ADMISSIBLE

Length	Admissible Words
1	*a, b*
2	*aa, ab, ba*
3	*aab, aba, baa*
4	*aaba abaa, baab*

so $B(1)=2$, $B(2)=3$, $B(3)=3$, $B(4)=3$, and so on. Notice that $B(n)\leq B(n+1)$, so the block growth function is always nondecreasing. This is because any ADMISSIBLE word of length n can be extended rightwards to produce an ADMISSIBLE word of length $n+1$. Moreover, suppose $B(n)=B(n+1)$ for some n. Then each admissible word of length n extends to a *unique* ADMISSIBLE word of length $n+1$.

For a SEQUENCE in which each substring of length n uniquely determines the next symbol in the SEQUENCE, there are only finitely many strings of length n, so the process must eventually cycle and the SEQUENCE must be eventually periodic. This gives us the following theorems:

1. If the SEQUENCE is eventually periodic, with least period p, then $B(n)$ is strictly increasing until it reaches p, and $B(n)$ is constant thereafter.
2. If the SEQUENCE is not eventually periodic, then $B(n)$ is strictly increasing and so $B(n)\geq n+1$ for all n. If a SEQUENCE has the property that $B(n)=n+1$ for all n, then it is said to have minimal block growth, and the SEQUENCE is called a STURMIAN SEQUENCE.

The block growth is also called the GROWTH FUNCTION or the COMPLEXITY of a SEQUENCE.

Block Matrix

A block matrix is a MATRIX that is defined using smaller matrices, called blocks. For example,

$$\begin{bmatrix} \mathsf{A} & \mathsf{B} \\ \mathsf{C} & \mathsf{D} \end{bmatrix}, \tag{1}$$

where A, B, C, and D are themselves matrices, is a block matrix. In the specific example

$$\mathsf{A}=\begin{bmatrix} 0 & 2 \\ 2 & 0 \end{bmatrix} \tag{2}$$

$$\mathsf{B}=\begin{bmatrix} 3 & 3 & 3 \\ 3 & 3 & 3 \end{bmatrix} \tag{3}$$

$$\mathsf{C}=\begin{bmatrix} 4 & 4 \\ 4 & 4 \\ 4 & 4 \end{bmatrix} \tag{4}$$

$$\mathsf{D}=\begin{bmatrix} 5 & 0 & 5 \\ 0 & 5 & 0 \\ 5 & 0 & 5 \end{bmatrix}, \tag{5}$$

it is the matrix

$$\begin{bmatrix} 0 & 2 & 3 & 3 & 3 \\ 2 & 0 & 3 & 3 & 3 \\ 4 & 4 & 5 & 0 & 5 \\ 4 & 4 & 0 & 5 & 0 \\ 4 & 4 & 5 & 0 & 5 \end{bmatrix}. \tag{6}$$

Block matrices can be created using `BlockMatrix[`*blocks*`]` in the *Mathematica* add-on package ``LinearAlgebra`MatrixMultiplication` `` (which can be loaded with the command ``<<LinearAlgebra` ``).

When two block matrices have the same shape and their diagonal blocks are square matrices, then they multiply similarly to MATRIX MULTIPLICATION. For example,

$$\begin{bmatrix} \mathsf{A}_1 & \mathsf{B}_1 \\ \mathsf{C}_1 & \mathsf{D}_1 \end{bmatrix}\begin{bmatrix} \mathsf{A}_2 & \mathsf{B}_2 \\ \mathsf{C}_2 & \mathsf{D}_2 \end{bmatrix} = \begin{bmatrix} \mathsf{A}_1\mathsf{A}_2+\mathsf{B}_1\mathsf{C}_2 & \mathsf{A}_1\mathsf{B}_2 \\ \mathsf{C}_1\mathsf{A}_2+\mathsf{D}_1\mathsf{C}_2 & \mathsf{C}_1\mathsf{B}_2+\mathsf{D}_1\mathsf{D}_2 \end{bmatrix}. \tag{7}$$

When the blocks are SQUARE MATRICES, the set of invertible block matrices form a group, which is a special case of the GENERAL LINEAR GROUP. In this case, it is $GL_2(R^*)$, the invertible two by two matrices with entries in the UNITS of a RING R, where here R is the ring of square matrices.

See also Block Diagonal Matrix, Cayley-Hamilton Theorem, Matrix, Ring

Blow-Up

A common mechanism which generates singularities from smooth initial conditions.

See also Blow-Up Lemma

Blow-Up Lemma

The blow-up lemma essentially says that regular pairs in Szemerédi's regularity lemma behave like complete bipartite graphs from the point of view of embedding bounded degree subgraphs.

In particular, given a graph R of order r, minimal vertex degree δ and maximal vertex degree Δ, then there exists an $\epsilon > 0$ such that the following holds. Let N be an arbitrary positive integer, and replace the vertices of R with pairwise disjoint N-sets $V_1, V_2, ..., V_r$ (blowing up). Now construct two graphs on the same vertex set $V = \cup V_i$. The graph $R(N)$ is obtained by replacing all edges of R with copies of the complete bipartite graph $K_{N, N}$, and construct a sparser graph by replacing the edges of R with some (ϵ, δ)-superregular pair. If a graph H with $\Delta(H) \leq \Delta$ is embeddable into $R(N)$, then it is already embeddable into G (Komlós *et al.* 1998).

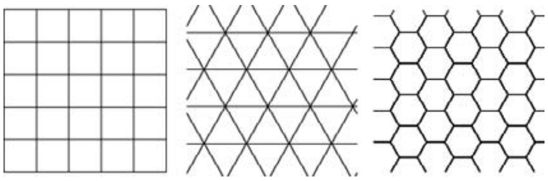
Blue-Empty Coloring

Blue-Empty Graph

Blue-Empty Graph

An extremal graph in which the forced triangles are all the same color. Call R the number of red monochromatic forced triangles and B the number of blue monochromatic forced triangles, then a blue-empty graph is an extremal graph with $B = 0$. For even n, a blue-empty graph can be achieved by coloring red two complete subgraphs of $n/2$ points (the red net method). There is no blue-empty coloring for odd n except for $n = 7$ (Lorden 1962).



See also Complete Graph, Extremal Graph, Monochromatic Forced Triangle, Red Net

Board

A board is a subset of the polygons determined by a number of (usually regularly spaced and oriented) lines. These polygons form the spaces on which "pieces" can be placed and move in many games (called board games). The simplest division the plane is into equal squares. The 3×3 square board is used in tic-tac-toe. The 8×8 square board is used in checkers and chess. Hexagonal boards are used in some games. Chinese checkers uses a board in the space of a pentagram with spaces at the vertices of a regular triangular tiling.

Bohemian Dome

A QUARTIC SURFACE which can be constructed as follows. Given a CIRCLE C and PLANE E PERPENDICULAR to the PLANE of C, move a second CIRCLE K of the same RADIUS as C through space so that its CENTER always lies on C and it remains PARALLEL to E. Then K sweeps out the Bohemian dome. It can be given by the PARAMETRIC EQUATIONS

$$x = a\cos u$$

$$y = b\cos v + a\sin u$$

$$z = c\sin v$$

where $u,\ v \in [0,\ 2\pi)$. In the above plot, $a = 0.5$, $b = 1.5$, and $c = 1$.

Bohr-Favard Inequalities

If f has no spectrum in $[-\lambda, \lambda]$, then

$$\|f\|_\infty \leq \frac{\pi}{2\lambda} \|f'\|_\infty$$

(Bohr 1935). A related inequality states that if A_k is the class of functions such that

$$f(x) = f(x+2\pi),\ f(x),\ f'(x),\ \ldots,\ f^{(k-1)}(x)$$

are absolutely continuous and $\int_0^{2\pi} f(x)\,dx = 0$, then

$$\|f\|_\infty \leq \frac{4}{\pi} \sum_{\nu=0}^{\infty} \frac{(-1)^{\nu(k+1)}}{(2\nu+1)^{k+1}} \left\|f^{(k)}(x)\right\|_\infty$$

(Northcott 1939). Further, for each value of k, there is always a function $f(x)$ belonging to A_k and not identically zero, for which the above inequality becomes an equality (Favard 1936). These inequalities are discussed in Mitrinovic *et al.* (1991).

Bohr-Mollerup Theorem

If a function $\varphi : (0, \infty) \to (0, \infty)$ satisfies

1. $\ln[\varphi(x)]$ is convex,
2. $\varphi(x+1) = x\varphi(x)$ for all $x > 0$, and
3. $\varphi(1) = 1$,

then $\varphi(x)$ is the GAMMA FUNCTION $\Gamma(x)$. Therefore, by ANALYTIC CONTINUATION, $\Gamma(z)$ is the only MEROMORPHIC FUNCTION on $\mathbb{C}$ satisfying the functional equation

$$z\Gamma(z) = \Gamma(z+1)$$

with $\Gamma(1) = 1$ and which is logarithmically convex on the positive REAL AXIS.

Bolzano Theorem

BOLZANO-WEIERSTRASS THEOREM

Bolzano-Weierstrass Theorem

Every BOUNDED infinite set in $\mathbb{R}^n$ has an ACCUMULATION POINT.

For $n = 1$, an infinite subset of a closed bounded set S has an ACCUMULATION POINT in S. For instance, given a bounded SEQUENCE a_π, with $-C \leq a_n \leq C$ for all n, it must have a MONOTONIC subsequence a_{n_k}. The SUBSEQUENCE a_{n_k} must converge because it is monotonic and bounded. Because S is closed, it contains the limit of a_{n_k}.

The Bolzano-Weierstrass theorem is closely related to the HEINE-BOREL THEOREM and CANTOR'S INTERSECTION THEOREM, each of which can be easily derived from either of the other two.

See also ACCUMULATION POINT, CANTOR'S INTERSECTION THEOREM, HEINE-BOREL THEOREM, INTERMEDIATE VALUE THEOREM

Bombieri Inner Product

For HOMOGENEOUS POLYNOMIALS P and Q of degree n,

$$[P,\ Q] \equiv \sum_{i_1,\ \ldots,\ i_n \geq 0} (i_1! \ldots i_n!)(a_{i_1,\ \ldots,\ i_n} b_{i_1,\ \ldots,\ i_n}).$$

Bombieri Norm

This entry contributed by KEVIN O'BRYANT

The Bombieri p-norm of a polynomial

$$Q(x) = \sum_{i=0}^{n} a_i x^i \tag{1}$$

is defined by

$$[Q]_p \equiv \left[\sum_{i=0}^{n} \binom{n}{i}^{1-p} |a_i|^p \right]^{1/p}, \tag{2}$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT. The most remarkable feature of Bombieri'sn norm is that given polynomials R and S such that $RS = Q$, then BOMBIERI'S INEQUALITY

$$[R]_2[S]_2 \leq \binom{n}{m}^{1/2} [Q]_2 \tag{3}$$

holds, where n is the degree of Q, and m is the degree of either R or S. This theorem captures the heuristic that if R and S have big coefficients, then so does RS, i.e., there can't be too much cancellation.

Bombieri's Inequality

For HOMOGENEOUS POLYNOMIALS P and Q of degree m and n, then

$$[P \cdot Q]_2 \geq \sqrt{\frac{m!n!}{(m+n)!}} [P]_2 [Q]_2,$$

where $[P \cdot Q]_2$ is the BOMBIERI NORM. If $m = n$, this becomes

$$[P \cdot Q]_2 \geq [P]_2 [Q]_2,$$

See also BOMBIERI NORM, BEAUZAMY AND DÉGOT'S IDENTITY, REZNIK'S IDENTITY

References

Borwein, P. and Erdélyi, T. "Bombieri's Norm." §5.3.E.7 in *Polynomials and Polynomial Inequalities.* New York: Springer-Verlag, p. 274, 1995.

Bombieri's Theorem

Define

$$E(x;\ q,\ a) \equiv \psi(x;\ q,\ a) - \frac{x}{\phi(q)}, \tag{1}$$

where

$$\psi(x;\ q,\ a) = \sum_{\substack{n \leq x \\ n \equiv a \pmod{q}}} \Lambda(n) \tag{2}$$

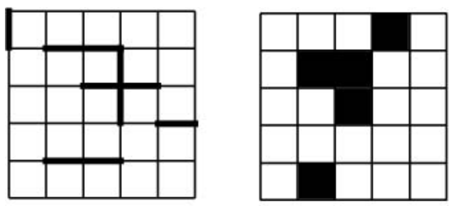
(Davenport 1980, p. 121), $\Lambda(n)$ is the MANGOLDT FUNCTION, and $\phi(q)$ is the TOTIENT FUNCTION. Now define

$$E(x;\ q) = \max_{\substack{a \\ (a,\ q)=1}} |E(x;\ q,\ a)| \tag{3}$$

where the sum is over a RELATIVELY PRIME to q, $(a,\ q) = 1$, and

$$E^*(x,\ q) = \max_{y \leq x} E(y,\ q). \tag{4}$$

Bombieri's theorem then says that for fixed $A > 0$,



$$\sum_{q \leq Q} E^*(x,\ q) \ll \sqrt{x} Q (\ln x)^5, \tag{5}$$

provided that $\sqrt{x}(\ln x)^{-4} < Q < \sqrt{x}$.

Bond Percolation

bond percolation *site percolation*

A PERCOLATION which considers the lattice edges as the relevant entities (left figure).

See also PERCOLATION THEORY, SITE PERCOLATION

Bonferroni Correction

The Bonferroni correction is a multiple-comparison correction used when several independent STATISTICAL TESTS are being performed simultaneously (since while a given ALPHA VALUE α may be appropriate for each individual comparison, it is not for the set of *all* comparisons). In order to avoid a lot of spurious positives, the ALPHA VALUE needs to be lowered to account for the number of comparisons being performed.

The simplest and most conservative approach is the Bonferroni correction, which sets the ALPHA VALUE for the entire *set* of n comparisons equal to α by taking the ALPHA VALUE for *each* comparison equal to α/n. Explicitly, given n tests T_i for hypotheses H_i ($1 \leq i \leq n$) under the assumption H_0 that all hypotheses H_i are false, and if the individual test critical values are $\leq \alpha/n$, then the experiment-wide critical value is $\leq \alpha$. In equation form, if

$$P(T_i \text{ passes } |H_0) \leq \frac{\alpha}{n}$$

for $1 \leq i \leq n$, then

$$P(\text{some } T_i \text{ passes } |H_0) \leq \alpha,$$

which follows from BONFERRONI'S INEQUALITIES.

Another correction instead uses $1-(1-\alpha)^{1/n}$. While this choice is applicable for two-sided hypotheses, multivariate normal statistics, and positive orthant dependent statistics, it is not, in general, correct (Shaffer 1995).

Bonne Projection

A MAP PROJECTION which resembles the shape of a heart. Let ϕ_1 be the standard parallel, λ_0 the central meridian, ϕ be the LATITUDE, and λ the LONGITUDE on a UNIT SPHERE. Then

$$x = \rho \sin E \tag{1}$$

$$y = \cot \phi_1 - \rho \cos E, \tag{2}$$

where

$$\rho = \cot \phi_1 + \phi_1 - \phi \tag{3}$$

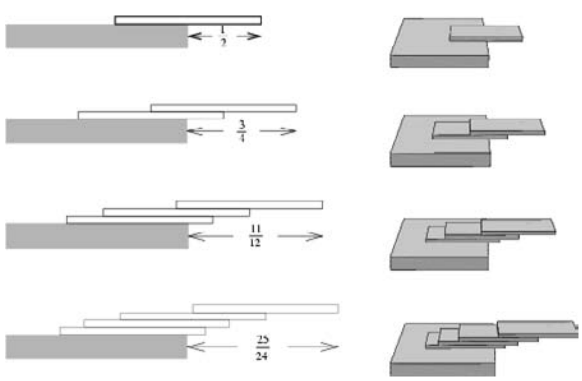
$$E = \frac{(\lambda - \lambda_0)\cos\phi}{\rho}. \tag{4}$$

The inverse FORMULAS are

$$\phi = \cot \phi_1 + \phi_1 - \rho \quad (5)$$

$$\lambda = \lambda_0 + \frac{\rho}{\cos \phi} \tan^{-1}\left(\frac{x}{\cot \phi_1 - y}\right), \quad (6)$$

where



$$\rho = \pm\sqrt{x^2 + (\cot \phi_1 - y)^2}. \quad (7)$$

The WERNER PROJECTION is a special case of the Bonne projection.

Book Stacking Problem

How far can a stack of n books protrude over the edge of a table without the stack falling over? It turns out that the maximum overhang possible d_n for n books (in terms of book lengths) is half the nth partial sum of the HARMONIC SERIES, given explicitly by

$$d_n = \frac{1}{2}\sum_{k=1}^{n}\frac{1}{k} = \tfrac{1}{2}[\gamma + \Psi(1+n)]$$

where $\Psi(z)$ is the DIGAMMA FUNCTION and γ is the EULER-MASCHERONI CONSTANT. The first few values are

$$d_1 = \tfrac{1}{2} = 0.5$$

$$d_2 = \tfrac{3}{4} = 0.75$$

$$d_3 = \tfrac{11}{12} \approx 0.91667$$

$$d_4 = \tfrac{25}{24} \approx 1.04167,$$

(Sloane's A001008 and A002805).

In order to find the number of stacked books required to obtain d book-lengths of overhang, solve the d_n equation for d, and take the CEILING FUNCTION. For $n = 1, 2, \ldots$ book-lengths of overhang, 4, 31, 227, 1674, 12367, 91380, 675214, 4989191, 36865412, 272400600, ... (Sloane's A014537) books are needed.

Boole

IVERSON BRACKET

Boole Polynomial

Polynomials $s_k(x;\ \lambda)$ which form a SHEFFER SEQUENCE with

$$g(t) = 1 + e^{\lambda t} \quad (1)$$

$$f(t) = e^t - 1 \quad (2)$$

and have GENERATING FUNCTION

$$\sum_{k=0}^{\infty}\frac{s_k(x;\ \lambda)}{\kappa!}t^k = \frac{(1+t)^x}{1+(1+t)^\lambda}. \quad (3)$$

The first few are

$$s_0(x;\ \lambda) = \tfrac{1}{2}$$
$$s_1(x;\ \lambda) = \tfrac{1}{4}(2x - \lambda)t$$
$$x_2(x;\ \lambda) = \tfrac{1}{4}[2x(x - \lambda - 1) + \lambda].$$

Jordan (1950) considers the related polynomials $r_n(x)$

which form a SHEFFER SEQUENCE with

$$g(t) = \tfrac{1}{2}(1 + e^t) \tag{4}$$

$$f(t) = e^t - 1. \tag{5}$$

These polynomials have GENERATING FUNCTION

$$\sum_{k=0}^{\infty} \frac{r_n(x)}{k!} t^k = \frac{2(1+t)^x}{2+t}. \tag{6}$$

The first few are

$$r_0(x) = 1$$
$$r_1(x) = \tfrac{1}{2}(2x - 1)$$
$$r_2(x) = \tfrac{1}{2}(2x^2 - 4x + 1)$$
$$r_3(x) = \tfrac{1}{4}(4x^3 - 18x^2 + 20x - 3).$$

The PETERS POLYNOMIALS are a generalization of the Boole polynomials.

See also PETERS POLYNOMIAL

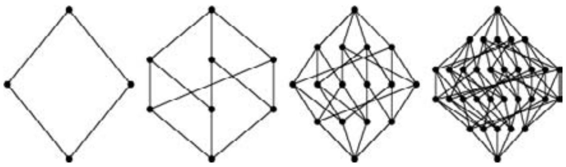
Boole's Inequality

Let $P(E_i)$ be the probability of an event E_i occurring. Then

$$P\left(\bigcup_{i=1}^{N} E_i\right) \leq \sum_{i=1}^{N} P(E_i),$$



where $\cup$ denotes the UNION. If E_i and E_j are DISJOINT SETS for all i and j, then the INEQUALITY becomes an equality.

See also DISJOINT SETS, UNION

Boolean Algebra

A mathematical structure which is similar to a BOOLEAN RING, but which is defined using the meet and join operators instead of the usual addition and multiplication operators. Explicitly, a Boolean algebra is the PARTIAL ORDER on subsets defined by inclusion (Skiena 1990, p. 207), i.e., the Boolean algebra $b(A)$ of a set A is the set of subsets of A that can be obtained by means of a finite number of the set operations UNION (OR), INTERSECTION (AND), and COMPLEMENTATION (NOT) (Comtet 1974, p. 185). A Boolean algebra also forms a LATTICE (Skiena 1990, p. 170), and each of the elements of $b(A)$ is called a BOOLEAN FUNCTION. There are 2^{2^n} BOOLEAN FUNCTIONS in a Boolean algebra of order n (Comtet 1974, p. 186).

In 1938, Shannon proved that a two-valued Boolean algebra (whose members are most commonly denoted 0 and 1, or false and true) can describe the operation of two-valued electrical switching circuits. In modern times, Boolean algebra and BOOLEAN FUNCTIONS are therefore indispensable in the design of computer chips and integrated circuits.

Boolean algebras have a recursive structure apparent in the HASSE DIAGRAMS illustrated above for Boolean algebras of orders $n = 2$, 3, 4, and 5. These figures illustrate the partition between left and right halves of the lattice, each of which is the Boolean algebra on $n - 1$ elements (Skiena 1990, pp. 169–70).

A Boolean algebra can be formally defined as a SET B of elements a, b, ... with the following properties:

1. B has two binary operations, $\wedge$ (logical AND, or "WEDGE") and $\vee$ (logical OR, or "VEE"), which satisfy the IDEMPOTENT laws

$$a \wedge a = a \vee a = a, \tag{1}$$

the COMMUTATIVE laws

$$a \wedge b = b \wedge a \tag{2}$$

$$a \vee b = b \vee a, \tag{3}$$

and the ASSOCIATIVE laws

$$a \wedge (b \wedge c) = (a \wedge b) \wedge c \tag{4}$$

$$a \vee (b \vee c) = (a \vee b) \vee c. \tag{5}$$

2. The operations satisfy the ABSORPTION LAW

$$a \wedge (a \vee b) = a \vee (a \wedge b) = a. \tag{6}$$

3. The operations are mutually distributive

$$a \wedge (b \vee c) = (a \wedge b) \wedge (a \wedge c) \tag{7}$$

$$a \vee (b \wedge c) = (a \vee b) \wedge (a \wedge c). \tag{8}$$

4. B contains universal bounds $\varnothing$ and I which satisfy

$$\varnothing \wedge a = \varnothing \tag{9}$$

$$\varnothing \vee a = a \tag{10}$$

$$I \wedge a = a \tag{11}$$

$$I \vee a = I. \tag{12}$$

5. B has a unary operation $a \to a'$ of complementation which obeys the laws

$$a \wedge a' = \varnothing \tag{13}$$

$$a \vee a' = I \tag{14}$$

(Birkhoff and Mac Lane 1965).

In the slightly archaic terminology of (Bell 1937, p. 444), a Boolean algebra can be defined as a set B of elements a, b, ... with BINARY OPERATORS $\vee$ (or $+$; logical OR) and $\wedge$ (or $\cdot$; logical AND) such that

1a. If a and b are in the set B, then $a \vee b$ is in the set B.
1b. If a and b are in the set B, then $a \wedge b$ is in the set B.
2a. There is an element Z (zero) such that $a \vee Z = a$ for every element a.
2b. There is an element U (unity) such that $a \wedge U = a$ for every element a.
3a. $a \vee b = b \vee a$.
3b. $a \wedge b = b \wedge a$.
4a. $a \vee b \wedge c = (a \vee b) \wedge (a \vee c)$.
4b. $a \wedge (b \vee c) = (a \wedge b) \vee (a \wedge c)$.
5. For every element a there is an element a' such that $a \vee a' = U$ and $a \wedge a' = Z$.
6. There are at least two distinct elements in the set B.

Huntington (1933ab) presented the following basis for Boolean algebra:

1. Commutativity. $x \vee y = y \vee x$.
2. Associativity. $(x \vee y) \vee z = x \vee (y \vee z)$.
3. HUNTINGTON AXIOM. $!(!x \vee y) \vee !(!x \vee !y) = x$.

H. Robbins then conjectured that the HUNTINGTON AXIOM could be replaced with the simpler ROBBINS AXIOM,

$$!(!(x \vee y) \vee !(x \vee !y)) = x \tag{15}$$

The ALGEBRA defined by commutativity, associativity, and the ROBBINS AXIOM is called ROBBINS ALGEBRA. Computer theorem proving demonstrated that every ROBBINS ALGEBRA satisfies the second WINKLER CONDITION, from which it follows immediately that all ROBBINS ALGEBRAS are Boolean (McCune, Kolata 1996).

Boolean Connective

One of the LOGIC operators AND $\wedge$, OR $\vee$, and NOT $\neg$.

See also QUANTIFIER

Boolean Function

Consider a Boolean algebra of subsets $b(A)$ generated by a set A, which is the set of subsets of A that can be obtained by means of a finite number of the set operations union, intersection, and complementation. Then each of the elements of $b(A)$ is called a Boolean function generated by A (Comtet 1974, p. 185). Each Boolean function has a unique representation (up to order) as a union of COMPLETE PRODUCTS. It follows that there are 2^{2^p} inequivalent Boolean functions for a set A with cardinality p (Comtet 1974, p. 187).

In 1938, Shannon proved that a two-valued Boolean algebra (whose members are most commonly denoted 0 and 1, or false and true) can describe the operation of two-valued electrical switching circuits. The following table gives the TRUTH TABLE for the $2^{2^2} = 16$ possible Boolean functions of two binary variables.

A	B	F_0	F_1	F_2	F_3	F_4	F_5	F_6	F_7
0	0	0	0	0	0	0	0	0	0
0	1	0	0	0	0	1	1	1	1
1	0	0	0	1	1	0	0	1	1
1	1	0	1	0	1	0	1	0	1

A	B	F_8	F_9	F_{10}	F_{11}	F_{12}	F_{13}	F_{14}	F_{15}
0	0	1	1	1	1	1	1	1	1
0	1	0	0	0	0	1	1	1	1

1	0	0	0	1	1	0	0	1	1
1	1	0	1	0	1	0	1	0	1

The names and symbols for these functions are given in the following table (Simpson 1987, p. 539).

operation	symbol	name
F_0	0	FALSE
F_1	$A \wedge B$	AND
F_2	$A \wedge !B$	A AND NOT B
F_3	A	A
F_4	$!A \wedge B$	NOT A AND B
F_5	B	B
F_6	$A \underline{\vee} B$	XOR
F_7	$A \vee B$	OR
F_8	$A \bar{\vee} B$	NOR
F_9	A XNOR B	XNOR
F_{10}	$!B$	NOT B
F_{11}	$A \vee !B$	A OR NOT B
F_{12}	$!A$	NOT A
F_{13}	$!A \vee B$	NOT A OR B
F_{14}	$A \bar{\wedge} B$	NAND
F_{15}	1	TRUE

Determining the number of *monotone* Boolean functions of n variables is known as DEDEKIND'S PROBLEM and is equivalent to the number of ANTICHAINS on the n-set $\{1, 2, \ldots, n\}$. Boolean functions can also be thought of as colorings of a Boolean n-cube. The numbers of inequivalent monotone Boolean functions in $n = 1, 2, \ldots$ variables are given by 2, 3, 5, 10, 30, ...(Sloane's A003182).

Let $M(n, k)$ denote the number of distinct monotone Boolean functions of n variables with k MINCUTS. Then

$$M(n, 0) = 1$$

$$M(n, 1) = 2^n$$

$$M(n, 2) = 2^{n-1}(2^n - 1) - 3^n + 2^n$$

$$M(n, 3) = \tfrac{1}{6}(2^n)(2^n - 1)(2^n - 2) - 6^n + 5^n + 4^n - 3^n.$$

Bordism

A relation between COMPACT boundaryless MANIFOLDS (also called closed MANIFOLDS). Two closed MANIFOLDS are bordant IFF their disjoint union is the boundary of a compact $(n+1)$-MANIFOLD. Roughly, two MANIFOLDS are bordant if together they form the boundary of a MANIFOLD. The word bordism is now used in place of the original term COBORDISM.

References
Budney, R. "The Bordism Project." http://www.math.cornell.edu/~rybu/bordism/bordism.html.

Bordism Group

There are bordism groups, also called COBORDISM GROUPS or COBORDISM RINGS, and there are singular bordism groups. The bordism groups give a framework for getting a grip on the question, "When is a compact boundaryless MANIFOLD the boundary of another MANIFOLD?" The answer is, precisely when all of its STIEFEL-WHITNEY CLASSES are zero. Singular bordism groups give insight into STEENROD'S REALIZATION PROBLEM: "When can homology classes be realized as the image of fundamental classes of manifolds?" That answer is known, too.

The machinery of the bordism group winds up being important for HOMOTOPY THEORY as well.

Budney, R. "The Bordism Project." http://www.math.cornell.edu/~rybu/bordism/bordism.html.

Borel Algebra

See also BOREL SIGMA ALGEBRA, BOREL SUBALGEBRA

Borel Determinacy Theorem

Let T be a TREE defined on a metric over a set of paths such that the distance between paths p and q is $1/n$, where n is the number of nodes shared by p and q. Let A be a BOREL SET of paths in the topology induced by this metric. Suppose two players play a game by choosing a path down the tree, so that they alternate and each time choose an immediate successor of the previously chosen point. The first player wins if the chosen path is in A. Then one of the players has a winning STRATEGY in this GAME.

See also GAME THEORY, TREE

Borel Field

If a FIELD has the property that, if the sets A_n, ..., A_n, ... belong to it, then so do the sets $A_1 + \ldots + A_n + \ldots$ and $A_1 \ldots A_n \ldots$, then the field is called a Borel field (Papoulis 1984, p. 29).

See also FIELD

References
Papoulis, A. *Probability, Random Variables, and Stochastic Processes, 2nd ed.* New York: McGraw-Hill, 1984.

Borel Measure

If F is the BOREL SIGMA ALGEBRA on some TOPOLOGICAL SPACE, then a MEASURE $m : F \to \mathbb{R}$ is said to be a Borel measure (or BOREL PROBABILITY MEASURE). For a Borel measure, all continuous functions are MEASURABLE.

Borel Probability Measure

BOREL MEASURE

Borel Set

A Borel set is an element of a BOREL SIGMA ALGEBRA. Roughly speaking, Borel sets are the sets that can be constructed from open or closed sets by repeatedly taking countable unions and intersections. Formally, the class B of Borel sets in Euclidean $\mathbb{R}^n$ is the smallest collection of sets that includes the open and closed sets such that if E, E_1, E_2, ... are in B, then so are $\cup_{i=1}^{\infty} E_i$, $\cap_{i=1}^{\infty} E_i$, and $\mathbb{R}^n \setminus E$, where $F \setminus E$ is a SET DIFFERENCE (Croft *et al.* 19991).

The set of rational numbers is a Borel set, as is the CANTOR SET.

See also CLOSED SET, OPEN SET, STANDARD SPACE

References

Croft, H. T.; Falconer, K. J.; and Guy, R. K. *Unsolved Problems in Geometry.* New York: Springer-Verlag, p. 3, 1991.

Borel Sigma Algebra

A SIGMA ALGEBRA which is related to the TOPOLOGY of a SET. The Borel σ-algebra is defined to be the SIGMA ALGEBRA generated by the OPEN SETS (or equivalently, by the CLOSED SETS).

See also BOREL ALGEBRA, BOREL MEASURE, BOREL SUBALGEBRA

Borel Space

A SET equipped with a SIGMA ALGEBRA of SUBSETS.

Borel Subalgebra

See also BOREL ALGEBRA, BOREL SIGMA ALGEBRA

Borel's Expansion

Let $\phi(t) = \Sigma_{n=0}^{\infty} A_n t^n$ be any function for which the integral

$$I(x) \equiv \int_0^{\infty} e^{-tx} t^p \phi(t)\, dt$$

converges. Then the expansion

$$I(x) \frac{\Gamma(p+1)}{x^{p+1}} \left[A_0 + (p+1)\frac{A_1}{x} + (p+1)(p+2)\frac{A_2}{x^2} + \ldots \right],$$

where $\Gamma(z)$ is the GAMMA FUNCTION, is usually an ASYMPTOTIC SERIES for $I(x)$.

Borel-Cantelli Lemma

Let $\{A_n\}_{n=0}^{\infty}$ be a SEQUENCE of events occurring with a certain probability distribution, and let A be the event consisting of the occurrence of a finite number of events A_n, $n = 1$, ... Then if

$$\sum_{n=1}^{\infty} P(A_n) < \infty,$$

then

$$P(A) = 1.$$

Borel-Weyl Theorem

Let $G = SL(n, \mathbb{C})$. If $\lambda \in Z^n$ is the highest weight of an irreducible holomorphic representation V of G, (i.e., λ is a dominant integral weight), then the G-map ϕ : $V^* \to \Gamma(\lambda)$ defined by $\alpha \mapsto F_\alpha$, where $F_\alpha(g) = \langle \alpha, gv \rangle$, is an ISOMORPHISM. Thus, $V \cong \Gamma(\lambda)^*$.

Boron Tree

BINARY TREE

Borromean Rings

Three mutually interlocked rings, named after the Italian Renaissance family who used them on their coat of arms. The configuration of rings is also known as a "Ballantine," and a brand of beer (illustrated above) has been brewed under this name. In the Borromean rings, no two rings are linked, so if any one of the rings is cut, all three rings fall apart. Any number of rings can be linked in an analogous manner (Steinhaus 1983, Wells 1991).

The Borromean rings have LINK symbol 06_{-3-2}, BRAID WORD $\sigma_1^{-1}\sigma_2\sigma_1^{-1}\sigma_2\sigma_1^{-1}\sigma_2$, and are also the simplest BRUNNIAN LINK.

Borrow

The procedure used in SUBTRACTION to "borrow" 10 from the next higher DIGIT column in order to obtain a POSITIVE DIFFERENCE in the column in question.

See also CARRY

Borsuk's Conjecture

Borsuk conjectured that it is possible to cut an n-D shape of GENERALIZED DIAMETER 1 into $n+1$ pieces each with diameter smaller than the original. It is true for $n = 2$, 3 and when the boundary is "smooth." However, the minimum number of pieces required has been shown to increase as $\sim 1.1^{\sqrt{n}}$. Since $1.1^{\sqrt{n}} > n+1$ at $n = 9162$, the conjecture becomes false at high dimensions. In fact, the conjecture is false for every $n > 561$.

Borwein Conjectures

Use the definition of the Q-SERIES

$$(a;\ q)_n \equiv \prod_{j=0}^{n-1}(1-aq^j) \tag{1}$$

and define

$$\begin{bmatrix} N \\ M \end{bmatrix} \equiv \frac{(q^{N-M+1;\ q})_M}{(q;\ q)_m}. \tag{2}$$

Then P. Borwein has conjectured that (1) the POLYNOMIALS $A_n(q)$, $B_n(q)$, and $C_n(q)$ defined by

$$(q;\ q^3)_n(q^2;\ q^3)_n = A_n(q^3) - qB_n(q^3) - q^2C_n(q^3) \tag{3}$$

have NONNEGATIVE COEFFICIENTS, (2) the POLYNOMIALS $A_n^*(q)$, $B_n^*(q)$, and $C_n^*(q)$ defined by

$$(q;\ q^3)_n^2(q^2;\ q^3)_n^2 = A_n^*(q^3) - qB_n^*(q^3) - q^2C_n^*(q^3) \tag{4}$$

have NONNEGATIVE COEFFICIENTS, (3) the POLYNOMIALS $A_n^*(q)$, $B_n^*(q)$, $C_n^*(q)$, $D_n^*(q)$, and $E_n^*(q)$ defined by

$$(q;\ q^5)_n(q^2;\ q^5)_n(q^3;\ q^5)_n(q^4;\ q^5)_n =$$
$$A_n^*(q^5) - qB_n^*(q^5) - q^2C_n^*(q^5) - q^3D_n^*(q^5) - q^4E_n^*(q^5) \tag{5}$$

have NONNEGATIVE COEFFICIENTS, (4) the POLYNOMIALS $A_n^\dagger(m,\ n,\ t,\ q)$, $B_n^\dagger(m,\ n,\ t,\ q)$, and $C_n^\dagger(m,\ n,\ t,\ q)$ defined by

$$(q;\ q^3)_m(q^2;\ q^3)_m(zq;\ q^3)_n(zq^2;\ q^3)_n$$
$$= \sum_{t=0}^{2m} z^t[A^\dagger(m,\ n,\ t,\ q^3) - qB^\dagger(m,\ n,\ t,\ q^3)$$
$$- q^2C^\dagger(m,\ n,\ t,\ q^3)] \tag{6}$$

have NONNEGATIVE COEFFICIENTS, (5) for k ODD and $1 \leq a \leq k/2$, consider the expansion

$$(q^a;\ q^k)_m(q^{k-a};\ q^k)_n = \sum_{v=(1-k)/2}^{(k-1)/2} (-1)^v q^{k(v^2+v)/2-av} F_v(q^k) \tag{7}$$

with

$$F_v(q) = \sum_{j=-\infty}^{\infty} (-1)^j q^{j(k^2j+2kv+k-2a)/2} \begin{bmatrix} m+n \\ m+v+kj \end{bmatrix}, \tag{8}$$

then if a is RELATIVELY PRIME to k and $m = n$, the COEFFICIENTS of $F_v(q)$ are NONNEGATIVE, and (6) given $\alpha + \beta < 2K$ and $-K + \beta \leq n - m \leq K - \alpha$, consider

$$G(\alpha,\ \beta,\ K;\ q)$$
$$= \sum_q (-1)^j q^{j[K(\alpha+\beta)j+K(\alpha+\beta)]/2} \begin{bmatrix} m+n \\ m+Kj \end{bmatrix}, \tag{9}$$

the GENERATING FUNCTION for partitions inside an $m \times n$ rectangle with hook difference conditions specified by α, β, and K. Let α and β be POSITIVE RATIONAL NUMBERS and $k > 1$ an INTEGER such that αk and βk are integers. then if $1 \leq \alpha + \beta \leq 2k - 1$ (with strict inequalities for $k = 2$) and $-k + \beta \leq n - m \leq k - \alpha$, then $g(\alpha,\ \beta,\ k;\ q)$ has NONNEGATIVE COEFFICIENTS.

Bottle Imp Paradox

In Robert Louis Stevenson's "bottle imp paradox," you are offered the opportunity to buy, for whatever price you wish, a bottle containing a genie who will fulfill your every desire. The only catch is that the bottle must thereafter be resold for a price smaller than what you paid for it, or you will be condemned to live out the rest of your days in excruciating torment. Obviously, no one would buy the bottle for 1c since he would have to give the bottle away, but no one would accept the bottle knowing he would be unable to get rid of it. Similarly, no one would buy it for 2c, and so on. However, for some reasonably large amount, it will always be possible to find a next buyer, so the bottle will be bought (Paulos 1995).

Bouligand Dimension

MINKOWSKI-BOULIGAND DIMENSION

Bound

GREATEST LOWER BOUND, INFIMUM, LEAST UPPER BOUND, SUPREMUM

Bound Variable

An occurrence of a variable in a LOGIC which is not FREE. Bound variables are also called DUMMY VARIABLES.

See also DUMMY VARIABLE, SENTENCE

References

Comtet, L. "Bound Variables." §1.11 in *Advanced Combinatorics: The Art of Finite and Infinite Expansions, rev. enl. ed.* Dordrecht, Netherlands: Reidel, pp. 30–4, 1974.

Boundary

The set of points, known as BOUNDARY POINTS, which are members of the CLOSURE of a given set S and the CLOSURE of its complement set. The boundary is sometimes called the FRONTIER.

See also BOUNDARY CONDITIONS, BOUNDARY MAP, BOUNDARY POINT, BOUNDARY SET, NATURAL BOUNDARY, SURGERY

Boundary Conditions

There are several types of boundary conditions commonly encountered in the solution of PARTIAL DIFFERENTIAL EQUATIONS.

1. DIRICHLET BOUNDARY CONDITIONS specify the value of the function on a surface $T=f(\mathbf{r},\ t)$.
2. NEUMANN BOUNDARY CONDITIONS specify the normal derivative of the function on a surface,

$$\frac{\partial T}{\partial n}=\hat{\mathbf{n}}\cdot\nabla T=f(\mathbf{r},\ y).$$

3. CAUCHY BOUNDARY CONDITIONS specify a weighted average of first and second kinds.
4. ROBIN BOUNDARY CONDITIONS. For an elliptic partial differential equation in a region Ω, Robin boundary conditions specify the sum of αu and the normal derivative of $u\ =\ f$ at all points of the boundary of Ω, with α and f being prescribed.

See also BOUNDARY VALUE PROBLEM, DIRICHLET BOUNDARY CONDITIONS, GOURSAT PROBLEM, INITIAL VALUE PROBLEM, NEUMANN BOUNDARY CONDITIONS, PARTIAL DIFFERENTIAL EQUATION, ROBIN BOUNDARY CONDITIONS

Boundary Map

The MAP $H_n(X,\ A)\to H_{n-1}(A)$ appearing in the LONG EXACT SEQUENCE OF A PAIR AXIOM.

See also LONG EXACT SEQUENCE OF A PAIR AXIOM

Boundary Point

A point which is a member of the CLOSURE of a given set S and the CLOSURE of its complement set. If A is a subset of $\mathbb{R}^n$, then a point $\mathrm{x}\in\mathbb{R}^n$ is a boundary point of A if every NEIGHBORHOOD of $\mathbf{x}$ contains at least one point in A and at least one point not in A.

See also BOUNDARY

Boundary Set

A (symmetrical) boundary set of RADIUS r and center $\mathbf{x}_0$ is the set of all points $\mathbf{x}$ such that

$$|\mathbf{x}-\mathbf{x}_0|=r.$$

Let $\mathbf{x}_0$ be the ORIGIN. In $\mathbb{R}^1$, the boundary set is then the pair of points $x=r$ and $x=-r$. In $\mathbb{R}^2$, the boundary set is a CIRCLE. In $\mathbb{R}^3$, the boundary set is a SPHERE.

See also CIRCLE, COMPACT SET, DISK, OPEN SET, SPHERE

References

Croft, H. T.; Falconer, K. J.; and Guy, R. K. *Unsolved Problems in Geometry.* New York: Springer-Verlag, p. 2, 1991.

Boundary Value Problem

A boundary value problem is a problem, typically an ORDINARY DIFFERENTIAL EQUATION or a PARTIAL DIFFERENTIAL EQUATION, which has values assigned on the physical boundary of the DOMAIN in which the problem is specified. For example,

$$\begin{cases}\dfrac{\partial^2 u}{\partial t^2}-\nabla^2 u=f & \text{in }\Omega\\ u(0,\ t)=u_1 & \text{on }\partial\Omega\\ \dfrac{\partial u}{\partial t}(0,\ t)=u_2 & \text{on }\partial\Omega,\end{cases}$$

where $\partial\Omega$ denotes the boundary of Ω, is a boundary problem.

See also BOUNDARY CONDITIONS, INITIAL VALUE PROBLEM

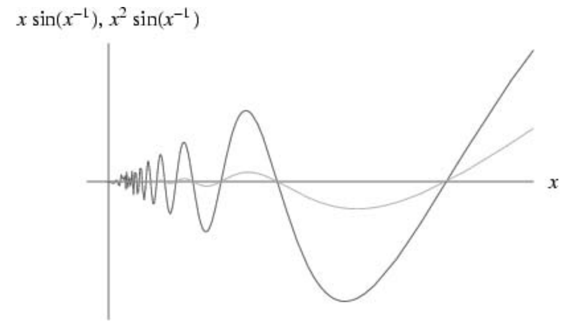
Bounded Variation

A FUNCTION $f(x)$ is said to have bounded variation if, over the CLOSED INTERVAL $x \in [a, b]$, there exists an M such that



$$|f(x_i) - f(a)| + |f(x_2) - f(x_1)| + \ldots + |f(b) - f(x_n - 1)| \leq M \quad (1)$$

for all $a < x_1 < x_2 < \ldots < x_{n-1} < b$.

The space of functions of bounded variation is denoted "BV," and has the SEMINORM

$$\Phi(f) = \sup \int f \frac{d\phi}{dx}, \quad (2)$$

where ϕ ranges over all COMPACTLY SUPPORTED functions bounded by -1 and 1. The seminorm is equal to the SUPREMUM over all sums above, and is also equal to $\int |df/dx|\, dx$ (when this expression makes sense).

On the interval [0, 1], the function $x^2 \sin(1/x)$ (purple) is of bounded variation, but $x \sin 1/x$ (red) is not. More generally, a function f is locally of bounded variation in a domain U if f is LOCALLY INTEGRABLE, $f \in L^1_{\text{loc}}$, and for all open subsets W, with COMPACT CLOSURE in U, and all SMOOTH VECTOR FIELDS g COMPACTLY SUPPORTED in W,

$$\int_W f \operatorname{div} g dx \leq c(W) \sup|g|, \quad (3)$$

div denotes DIVERGENCE and c is a constant which only depends on the choice of W and f.

Such functions form the space $BV_{\text{loc}}(U)$. They may not be DIFFERENTIABLE, but by the RIESZ REPRESENTATION THEOREM, the derivative of a BV_{loc}-function f is a REGULAR BOREL MEASURE Df. Functions of bounded variation also satisfy a compactness theorem.

Given a sequence f_n of functions in $\text{BV}_{\text{loc}}(U)$, such that

$$\sup_n \left(\|f_n\|_{L^1(W)} + \int_W |Df_n|\, dx \right) < \infty,$$

that is the TOTAL VARIATION of the functions is bounded, in any COMPACTLY SUPPORTED open subset W, there is a SUBSEQUENCE f_{n_k} which converges to a function $f \in \text{BV}_{\text{loc}}$ in the topology of L^1_{loc}. Moreover, the limit satisfies

$$\int_W |Df|\, dx \leq \liminf \int_W |Df_{n_k}|\, dx. \quad (4)$$

They also satisfy a version of POINCARÉ'S LEMMA.

Bour's Minimal Surface

Gray (1997) defines Bour's minimal curve over complex z by

$$x' = \frac{z^{m-1}}{m-1} - \frac{z^{m+1}}{m+1} \quad (1)$$

$$y' = i\left(\frac{z^{m-1}}{m-1} + \frac{z^{m+1}}{m+1}\right) \quad (2)$$

$$z' = \frac{2z^m}{m}, \quad (3)$$

and then derives a family of MINIMAL SURFACES.

The order three Bour surface resembles a CROSS-CAP and is given using ENNEPER-WEIERSTRASS PARAMETERIZATION by

$$f = 1 \quad (4)$$

$$g = \sqrt{z} \quad (5)$$

or explicitly by the PARAMETRIC EQUATIONS

$$x = r\cos\theta - \tfrac{1}{2}r^2\cos(2\theta) \quad (6)$$

$$y = -r\sin\theta - \tfrac{1}{2}r^2\sin(2\theta), \quad (7)$$

$$z = \tfrac{4}{3}r^{3/2}\cos(\tfrac{3}{2}\theta) \quad (8)$$

(Maeder 1997). The coefficients of the FIRST FUNDAMENTAL FORM are given by

$$E = 1 + r^2 \quad (9)$$

$$F = 0 \quad (10)$$

$$G = r^2(r^2+1) \quad (11)$$

and the coefficients of the SECOND FUNDAMENTAL FORM by

$$e = -r^{-1/2}\cos(\tfrac{3}{2}\phi) \quad (12)$$

$$f = \sqrt{r}\sin(\tfrac{3}{2}\phi) \quad (13)$$

$$g = r^{3/2}\cos(\tfrac{3}{2}\phi). \quad (14)$$

The AREA ELEMENT is

$$dA = r(r+1)^2\, dr \wedge d\phi. \quad (15)$$

The GAUSSIAN and MEAN CURVATURES are given by

$$K = -\frac{1}{r(r+1)^4} \quad (16)$$

$$H = 0. \quad (17)$$

Bourget Function

The function defined by the CONTOUR INTEGRAL

$$J_{n,k}(z) = \frac{1}{2\pi i}\int^{(0+)} t^{-n-1}\left(t+\frac{1}{t}\right)^k \exp\left[\tfrac{1}{2}z\left(t-\frac{1}{t}\right)\right]dt,$$

where $\int_{(0+)}$ denotes the CONTOUR encircling the point $z = 0$ once in a counterclockwise direction. It is equal to

$$J_{n,k}(z) = \frac{1}{\pi}\int_0^\pi (2\cos\theta)^k \cos(n\theta - z\sin\theta)\,d\theta$$

(Watson 1966, p. 326).

Bourget's Hypothesis

When n is an INTEGER ≥ 0, then $J_n(z)$ and $J_{n+m}(z)$ have no common zeros other than at $z = 0$ for m an

INTEGER ≥ 1, where $J_n(z)$ is a BESSEL FUNCTION OF THE FIRST KIND. The theorem has been proved true for $m = 1$ 2, 3, and 4.

Boussinesq Equation

The linear Boussinesq equation is the PARTIAL DIFFERENTIAL EQUATION

$$u_{tt} - \alpha^2 u_{xx} = \beta^2 u_{xxtt} \tag{1}$$

(Whitham 1974, p. 9; Zwillinger 1997, p. 129). The nonlinear Boussinesq equation is

$$u_{tt} - u_{xx} - u_{xxxx} + 3(u^2)_{xx} = 0 \tag{2}$$

(Calogero and Degasperis 1982; Zwillinger 1997, p. 130). The modified Boussinesq equation is

$$\tfrac{1}{3} u_{tt} - u_t u_{xx} - \tfrac{3}{2} u_x^2 u_{xx} + u_{xxxx} = 0 \tag{3}$$

(Clarkson 1986; Zwillinger 1997, p. 132).

Boustrophedon Transform

The boustrophedon ("ox-plowing") transform **b** of a sequence **a** is given by

$$b_n = \sum_{k=0}^{n} \binom{n}{k} a_k E_{n-k} \tag{1}$$

$$a_n = \sum_{k=0}^{n} (-1)^{n-k} \binom{n}{k} b_k E_{n-k} \tag{2}$$

for $n \geq 0$, where E_n is a SECANT NUMBER or TANGENT NUMBER defined by

$$\sum_{n=0}^{\infty} E_n \frac{x^n}{n!} = \sec x + \tan x. \tag{3}$$

The exponential generating functions of **a** and **b** are related by

$$\mathscr{B}(x) = (\sec x + \tan x)\mathscr{A}(x), \tag{4}$$

where the exponential generating function is defined by

$$\mathscr{A}(x) = \sum_{n=0}^{\infty} A_n \frac{x^n}{n!}. \tag{5}$$

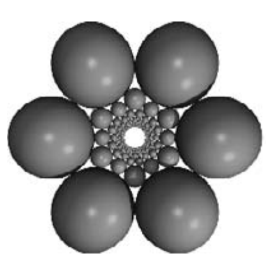
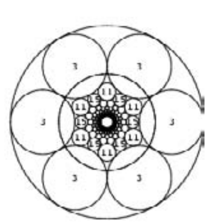
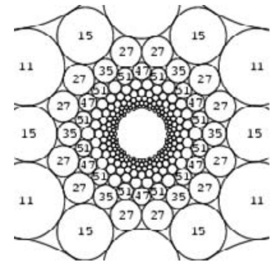
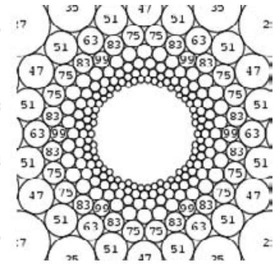
Bowditch Curve





LISSAJOUS CURVE

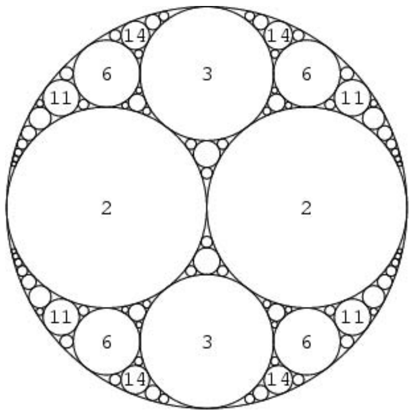




Bowl of Integers

Place two solid spheres of radius 1/2 inside a hollow sphere of radius 1 so that the two smaller circles touch each other at the center of the large circle and are tangent to the large circle on the extremities of one of its diameters. This arrangement is called the "bowl of integers" (Soddy 1937) since the BEND of each of the infinite chain of spheres that can be packed into it such that each successive sphere is tangent to its neighbors is an integer. The first few bends are then -1, 2, 5, 6, 9, 11, 14, 15, 18, 21, 23, ... (Sloane's A046160). The sizes and positions of the first few rings of spheres are given in the table below.

n	κ_n	z_n	R_n	ϕ_n
1	-1	0	0	–
2	2	$\frac{1}{2}$	0	–
3	5	$\frac{2}{5}$	$\frac{2}{5}\sqrt{3}$	$\frac{1}{6}\pi$
4	6	$\frac{1}{2}$	$\frac{2}{3}$	0
5	9	$\frac{2}{3}$	$\frac{2}{9}\sqrt{7}$	$\pm\tan^{-1}(\frac{1}{2}\sqrt{3})$
6	11	$\frac{8}{11}$	$\frac{6}{11}$	0
7	14	$\frac{11}{14}$	$\frac{2}{7}\sqrt{3}$	$\frac{1}{6}\pi$
8	15	$\frac{4}{5}$	$\frac{2}{15}\sqrt{13}$	$\pm\tan^{-1}(2\sqrt{3})$
9	18	$\frac{5}{6}$	$\frac{4}{9}$	0
10	21	$\frac{6}{7}$	$\frac{1}{21}\sqrt{19}$	$\pm\tan^{-1}(\frac{3}{7}\sqrt{3})$
11	23	$\frac{20}{23}$	$\frac{2}{23}\sqrt{21}$	$\pm\tan^{-1}(\frac{1}{9}\sqrt{3})$
12	27	$\frac{8}{9}$	$\frac{10}{27}$	$0, \pm\tan^{-1}(\frac{1}{3}\sqrt{3})$
13	30	$\frac{9}{10}$	$\frac{2}{15}\sqrt{7}$	$\pm\tan^{-1}(\frac{1}{5}\sqrt{3})$
14	33	$\frac{10}{11}$	$\frac{2}{33}\sqrt{31}$	$\pm\tan^{-1}(\frac{1}{11}\sqrt{3})$
15	38	$\frac{35}{38}$	$\frac{6}{19}$	0



Spheres can also be packed along the plane tangent to the two spheres of radius 2 (Soddy 1937). The sequence of integers for can be found using the equation of five TANGENT SPHERES. Letting $\kappa_3 = \kappa_4 = 2$ gives

$$\kappa(\kappa_1,\ \kappa_2)$$

$$= \tfrac{1}{2}(4 + \kappa_1 + \kappa_2 + \sqrt{3[\kappa_2(8-\kappa_2) + 2\kappa_1(\kappa_2+4) - 3\kappa_1^2}).$$

For example, $\kappa(3,\ 3) = 11$, $\kappa(3,\ 11) = 15$, $\kappa(11,\ 15) = 27$, $\kappa(15,\ 27) = 35$, $\kappa(27,\ 27)47$, and so on, giving the sequence -1, 2, 3, 11, 15, 27, 35, 47, 51, 63, 75, 83, ... (Sloane's A046159). The sizes and positions of the first few rings of spheres are given in the table below.

n	κ_n	R_n	ϕ_n
1	-1	0	–
2	2	0	–
3	3	$\frac{2}{3}$	0
4	11	$\frac{2}{11}\sqrt{3}$	$\frac{1}{6}\pi$
5	15	$\frac{4}{15}$	0
6	27	$\frac{2}{27}\sqrt{7}$	$\pm\tan^{-1}(3\sqrt{3})$
7	35	$\frac{6}{35}$	0
8	47	$\frac{4}{47}\sqrt{3}$	$\frac{1}{6}\pi$
9	51	$\frac{2}{51}\sqrt{13}$	$\pm\tan^{-1}(\frac{3}{5}\sqrt{3})$
10	63	$\frac{8}{63}$	0
11	75	$\frac{2}{75}\sqrt{19}$	$\pm\tan^{-1}(5\sqrt{3})$
12	83	$\frac{2}{83}\sqrt{21}$	$\pm\tan^{-1}(\frac{5}{3}\sqrt{3})$
13	99	$\frac{10}{99}$	0
14	107	$\frac{6}{107}\sqrt{3}$	$\frac{1}{6}\pi$
15	111	$\frac{4}{111}\sqrt{7}$	$\pm\tan^{-1}(\frac{1}{2}\sqrt{3})$
16	123	$\frac{2}{123}\sqrt{31}$	$\pm\tan^{-1}(\frac{5}{7}\sqrt{3})$
17	143	$\frac{12}{143}$	0
18	147	$\frac{2}{147}\sqrt{37}$	$\pm\tan^{-1}(7\sqrt{3})$
19	155	$\frac{2}{155}\sqrt{39}$	$\pm\tan^{-1}(\frac{1}{6}\sqrt{3})$
20	171	$\frac{2}{171}\sqrt{43}$	$\pm\tan^{-1}(\frac{7}{5}\sqrt{3})$

The analogous problem of placing two circles of bend 2 inside a circle of bend -1 and then constructing chains of mutually tangent circles was considered by B. L. Galebach and A. R. Wilks. The circle have integral bends given by -1, 2, 3, 6, 11, 14, 15, 18, 23, 26, 27, 30, 35, 38, ... (Sloane's A042944). Of these, the only known numbers congruent to 2, 3, 6, 11 (mod 12) missing from this sequence are 78, 159, 207, 243, 246, 342, ... (Sloane's A042945), a sequence which is conjectured to be finite.

Kenney, J. F. and Keeping, E. S. *Mathematics of Statistics, Pt. 1, 3rd ed.* Princeton, NJ: Van Nostrand, p. 102, 1962.

Bowling

Bowling is a game played by rolling a heavy ball down a long narrow track and attempting to knock down ten pins arranged in the form of a TRIANGLE with its vertex oriented towards the bowler. The number 10 is, in fact, the TRIANGULAR NUMBER $T_4 = 4(4+1)/2 = 10$.

Two "bowls" are allowed per "frame." If all the pins are knocked down in the two bowls, the score for that frame is the number of pins knocked down. If some or none of the pins are knocked down on the first bowl, then all the pins knocked down on the second, it is called a "spare," and the number of points tallied is 10 plus the number of pins knocked down on the bowl of the next frame. If all of the pins are knocked down on the first bowl, the number of points tallied is 10 plus the number of pins knocked down on the next two bowls. Ten frames are bowled, unless the last frame is a strike or spare, in which case an additional bowl is awarded.

The maximum number of points possible, corresponding to knocking down all 10 pins on every bowl, is 300.

Box

CUBOID

Box Counting Dimension

CAPACITY DIMENSION

Box Fractal

A FRACTAL also called the anticross-stitch curve which can be constructed using STRING REWRITING by creating a matrix with 3 times as many entries as

the current matrix using the rules

line 1 : "*" → "* *", " " → "   "
line 2 : "*" → " * ", " " → "   "
line 3 : "*" → "* *", " " → "   "

Let N_n be the number of black boxes, L_n the length of a side of a white box, and A_n the fractional AREA of black boxes after the nth iteration.

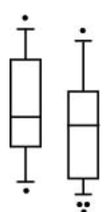
$$N_n = 5^n \tag{1}$$

$$L_n = (\tfrac{1}{3})^n = 3^{-n} \tag{2}$$

$$A_n = L_n^2\, N_n = (\tfrac{5}{9})^n. \tag{3}$$

The CAPACITY DIMENSION is therefore

$$d_{\text{cap}} = -\lim_{n\to\infty} \frac{\ln N_n}{\ln L_n} = -\lim_{n\to\infty} \frac{\ln(5^n)}{\ln(3^{-n})}$$



$$= \frac{\ln 5}{\ln 3} = 1.464973521\ldots. \tag{4}$$

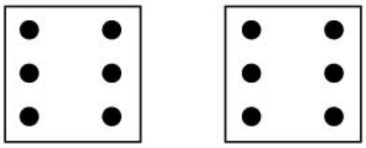
Tukey, J. W. *Explanatory Data Analysis.* Reading, MA: Addison-Wesley, pp. 39–1, 1977.

Boxcar Function

The function

$$B_e(a,\ b) = c[H(x-a) - H(x-b)]$$



which is equal to c for $a \le x \le b$ and 0 otherwise. Here $H(x)$ is the HEAVISIDE STEP FUNCTION. The special case $B_1(-1/2,\ 1/2)$ gives the unit RECTANGLE FUNCTION.

See also HEAVISIDE STEP FUNCTION, RECTANGLE FUNCTION

References

von Seggern, D. *CRC Standard Curves and Surfaces.* Boca Raton, FL: CRC Press, p. 324, 1993.

Boxcars

A roll of two 6s (the highest roll possible) on a pair of 6-sided DICE. The probability of rolling boxcars in a single roll of two dice is 1/36, or 2.777...%. In order to have a 50% chance of obtaining at least one boxcars in n rolls of two dice, it must be true that

$$1\left(\frac{35}{36}\right)^n = \frac{1}{2}, \tag{1}$$

so solving for n gives

$$n = \frac{\ln 2}{\ln 36 - \ln 35} = 24.605\ldots. \tag{2}$$

In fact, rolling two dice 25 times gives a probability of

$$1 - \left(\frac{35}{36}\right)^{25} \approx 0.505532 \tag{3}$$

that at least once boxcars will occur.

Box-Counting Dimension

CAPACITY DIMENSION

Box-Muller Transformation

A transformation which transforms from a 2-D continuous UNIFORM DISTRIBUTION to a 2-D GAUSSIAN BIVARIATE DISTRIBUTION (or COMPLEX GAUSSIAN DISTRIBUTION). If x_1 and x_2 are uniformly and independently distributed between 0 and 1, then z_1 and z_2 as defined below have a GAUSSIAN DISTRIBUTION with MEAN $\mu = 0$ and VARIANCE $\sigma^2 = 1$.

$$z_1 = \sqrt{-2 \ln x_1} \cos(2\pi x_2) \quad (1)$$

$$z_2 = \sqrt{-2 \ln x_1} \sin(2\pi x_2). \quad (2)$$

This can be verified by solving for x_1 and x_2,

$$x_1 = e^{-(z_1^2 + z_2^2)/2} \quad (3)$$

$$x_2 = \frac{1}{2\pi} \tan^{-1}\left(\frac{z_2}{z_1}\right). \quad (4)$$

Taking the JACOBIAN yields

$$\frac{\partial(x_1, x_2)}{\partial(z_1, z_2)} = \begin{vmatrix} \frac{\partial x_1}{\partial z_1} & \frac{\partial x_1}{\partial z_2} \\ \frac{\partial x_2}{\partial z_1} & \frac{\partial x_2}{\partial z_2} \end{vmatrix}$$

$$= -\left[\frac{1}{\sqrt{2\pi}} e^{-z_1^2/2}\right]\left[\frac{1}{\sqrt{2\pi}} e^{-z_2^2/2}\right]. \quad (5)$$

Boy Surface

A NONORIENTABLE SURFACE which is one of the three possible SURFACES obtained by sewing a MÖBIUS STRIP to the edge of a DISK. The other two are the CROSS-CAP and ROMAN SURFACE. The Boy surface is a model of the PROJECTIVE PLANE without singularities and is a SEXTIC SURFACE. The Boy surface can be described using the general method for NONORIENTABLE SURFACES, but this was not known until the analytic equations were found by Apéry (1986). Based on the fact that it had been proven impossible to describe the surface using quadratic polynomials, Hopf had conjectured that quartic polynomials were also insufficient (Pinkall 1986). Apéry's IMMERSION proved this conjecture wrong, giving the equations explicitly in terms of the standard form for a NONORIENTABLE SURFACE,

$$f_1(x, y, z) = \tfrac{1}{2}[(2x^2 - y^2 - z^2)(x^2 + y^2 + z^2) + 2yz(y^2 - z^2) + zx(x^1 - z^2) + xy(y^2 - x^2)] \quad (1)$$

$$f_2(x, y, z) = \tfrac{1}{2}\sqrt{3}[(y^2 - z^2)(x^2 + y^2 + z^2) + zx(z^2 - x^2) + xy(y^2 - x^2)] \quad (2)$$

$$f_3(x, y, z) = \tfrac{1}{8}(x + y + z) \times [(x + y + z)^3 + 4(y - x)(z - y)(x - z)]. \quad (3)$$

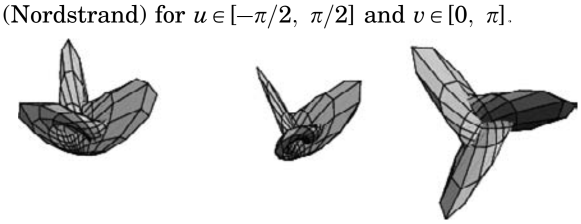
Plugging in

$$x = \cos u \sin v \quad (4)$$

$$y = \sin u \sin v \quad (5)$$

$$z = \cos v \quad (6)$$

and letting $u \in [0, \pi]$ and $v \in [0, \pi]$ then gives the Boy surface, three views of which are shown above.



The $\mathbb{R}^3$ parameterization can also be written as

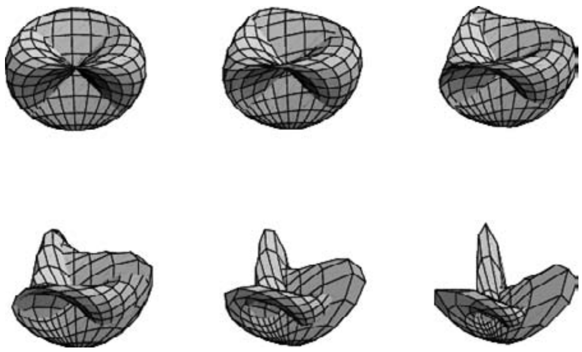
$$x = \frac{\sqrt{2} \cos^2 v \cos(2u) + \cos u \sin(2v)}{2 - \sqrt{2} \sin(3u) \sin(2v)} \quad (7)$$

$$y = \frac{\sqrt{2} \cos^2 v \cos(2u) + \cos u \sin(2v)}{2 - \sqrt{2} \sin(3u) \sin(2v)} \quad (8)$$

$$z = \frac{2 \cos^2 v}{2 - \sqrt{2} \sin(3u) \sin(2v)} \quad (9)$$

(Nordstrand) for $u \in [-\pi/2, \pi/2]$ and $v \in [0, \pi]$.

Three views of the surface obtained using this parameterization are shown above.



In fact, a HOMOTOPY (smooth deformation) between the ROMAN SURFACE and Boy surface is given by the equations

$$x(u, v) = \frac{\sqrt{2}\cos(2u)\cos^2 v + \cos u \sin(2v)}{2 - \alpha\sqrt{2}\sin(3u)\sin(2v)} \quad (10)$$

$$y(u, v) = \frac{\sqrt{2}\sin(2u)\cos^2 v - \sin u \sin(2v)}{2 - \alpha\sqrt{2}\sin(3u)\sin(2v)} \quad (11)$$

$$z(u, v) = \frac{3\cos^2 v}{2 - \alpha\sqrt{2}\sin(3u)\sin(2v)} \quad (12)$$

as α varies from 0 to 1, where $\alpha = 0$ corresponds to the ROMAN SURFACE and $\alpha = 1$ to the Boy surface (Wang), shown below.

In $\mathbb{R}^4$, the parametric representation is

$$x_0 = 3[(u^2 + v^2 + w^2)(u^2 + v^2) - \sqrt{2}\, vw(3u^2 - v^2)] \quad (13)$$

$$x_1 = \sqrt{2}(u^2 + v^2)(u^2 - v^2 + \sqrt{2}\, uw) \quad (14)$$

$$x_2 = \sqrt{2}(u^2 + v^2)(2uv - \sqrt{2}\, vw) \quad (15)$$

$$x_3 = 3(u^2 + v^2)^2, \quad (16)$$

and the algebraic equation is

$$\begin{aligned} &64(x_0 - x_3)^3 x_3^3 - 48(x_0 - x_3)^2 x_3^2 (3x_1^2 + 3x_2^2 + 2x_3^2) \\ &\quad + 12(x_0 - x_3)x_3[27(x_1^2 + x_2^2)^2 - 24x_3^2(x_1^2 + x_2^2) \\ &\quad + 36\sqrt{2}x_2 x_3(x_2^2 - 3x_1^2) + x_3^4] + (9x_1^2 + 9x_2^2 - 2x_3^2) \\ &\quad \times[-81(x_1^2 + x_2^2)^2 - 72x_3^2(x_1^2 + x_2^2) \\ &\quad + 108\sqrt{2}\, x_1 x_3(x_1^2 - 3x_2^2) + 4x_3^4] = 0 \end{aligned} \quad (17)$$

(Apéry 1986). Letting

$$x_0 = 1 \quad (18)$$

$$x_1 = x \quad (19)$$

$$x_2 = y \quad (20)$$

$$x_3 = z \quad (21)$$

gives another version of the surface in $\mathbb{R}^3$.

Bp-Theorem

If $O_{p'}(G) = 1$ and if x is a p-element of G, then

$$L_{p'}(C_G(x) \leq E(C_G(x)),$$

where $L_{p'}$ is the p-LAYER.

Bra

A (COVARIANT) 1-VECTOR denoted $\langle\psi|$. The bra is DUAL to the CONTRAVARIANT KET, denoted $|\psi\rangle$. Taken together, the bra and KET form an ANGLE BRACKET (bra + ket = bracket). The bra is commonly encountered in quantum mechanics.

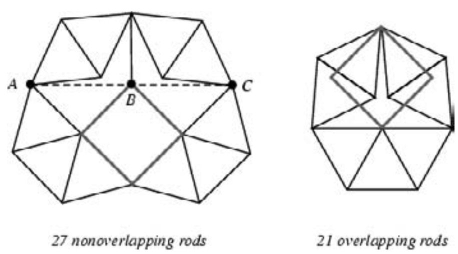
Brace

One of the symbols { and } used in many different contexts in mathematics. Braces are used

1. To denote grouping of mathematical terms, usually as the outermost delimiter in a complex expression such as $\{a + b[c + d(e + f)]\}$,
2. To delineate a SET, as in $\{a_1, \ldots, a_n\}$,
3. Using a left bracket only, to denote different cases for an expression, such as

$$p(n) = \begin{cases} 1 & \text{for } n \text{ even} \\ 0 & \text{for } n \text{ odd,} \end{cases}$$

4. Using a single horizontal underbrace, to indicate the number of items in a list with not all elements shown explicitly, as in $\underbrace{1, 1, \ldots, 1}$.



5. As an alternate notation to the FRACTIONAL PART function, $\{x\} = \text{frac } x$.

Braced Square

The braced square problem asks: given a hinged SQUARE composed of four equal rods (indicated by the thick lines above), how many more hinged rods must be added in the same plane (with no two rods crossing) so that the original square is rigid in the plane. The best solution known, illustrated in the left figure above, uses a total of 27 rods, where A, B, and C are COLLINEAR. If rods are allowed to cross, the best known solution, discovered by E. Friedman in Jan. 2000, requires 21 rods, as illustrated in the right figure above.

Friedman has also considered the minimum number of rods needed to construct RIGID regular n-gons (with overlapping permitted). The best known solutions for $n = 3, 4, \ldots$ are 3, 21, 69, 11, 45, 99, 51, ...

Brachistochrone Problem

Find the shape of the CURVE down which a bead sliding from rest and ACCELERATED by gravity will slip (without friction) from one point to another in the least time. The term derives from the Greek $\beta\rho\alpha\chi\iota\sigma\tau o\varsigma$ (*brachistos*) "the shortest" and $\chi\rho o\nu o\varsigma$ (*chronos*) "time, delay."

The brachistochrone problem was one of the earliest problems posed in the CALCULUS OF VARIATIONS. The solution, a segment of a CYCLOID, was found by Leibniz, L'Hospital, Newton, and the two Bernoullis. Johann Bernoulli solved the problem using the analogous one of considering the path of light refracted by transparent layers of varying density (Mach 1893, Gardner 1984, Courant and Robbins 1996). Note that bead may actually travel uphill along the cycloid for a distance, but the path is nonetheless faster than a straight line or any other line.

The time to travel from a point P_1 to another point P_2 is given by the INTEGRAL

$$t_{12} = \int_1^2 \frac{ds}{v}, \qquad (1)$$

The VELOCITY at any point is given by a simple application of energy conservation equating kinetic energy to gravitational potential energy,

$$\tfrac{1}{2}mv^2 = mgy, \qquad (2)$$

so

$$v = \sqrt{2gy}. \qquad (3)$$

Plugging this into (1) then gives

$$t_{12} = \int_1^2 \frac{\sqrt{1+y'^2}}{\sqrt{2gy}}\,dx = \int_1^2 \sqrt{\frac{1+y'^2}{2gy}}\,dx. \qquad (4)$$

The function to be varied is thus

$$f = (1+y'^2)^{1/2}(2gy)^{-1/2}, \qquad (5)$$

To proceed, one would normally have to apply the full-blown EULER-LAGRANGE DIFFERENTIAL EQUATION

$$\frac{\partial f}{\partial y} - \frac{d}{dx}\left(\frac{\partial f}{\partial y'}\right) = 0. \qquad (6)$$

However, the function $f(y, y', x)$ is particularly nice since x does not appear explicitly. Therefore, $\partial f/\partial x = 0$, and we can immediately use the BELTRAMI IDENTITY

$$f - y'\frac{\partial f}{\partial y'} = C. \qquad (7)$$

Computing

$$\frac{\partial f}{\partial y'} = y'(1+y'^2)^{-1/2}(2\,gy)^{-1/2}, \qquad (8)$$

subtracting $y'(\partial f/\partial y')$ from f, and simplifying then gives

$$\frac{1}{\sqrt{2gy}\sqrt{1+y'^2}} = C. \tag{9}$$

Squaring both sides and rearranging slightly results in

$$\left[1+\left(\frac{dy}{dx}\right)^2\right]y = \frac{1}{2g\,C^2} = k^2, \tag{10}$$

where the square of the old constant C has been expressed in terms of a new (POSITIVE) constant k^2. This equation is solved by the PARAMETRIC EQUATIONS

$$x = \tfrac{1}{2}k^2(\theta - \sin\theta) \tag{11}$$

$$y = \tfrac{1}{2}k^2(1 - \cos\theta), \tag{12}$$

which are–lo and behold–the equations of a CYCLOID.

If kinetic friction is included, the problem can also be solved analytically, although the solution is significantly messier. In that case, terms corresponding to the normal component of weight and the normal component of the ACCELERATION (present because of path CURVATURE) must be included. Including both terms requires a constrained variational technique (Ashby *et al.* 1975), but including the normal component of weight only gives an elementary solution. The TANGENT and NORMAL VECTORS are

$$\mathbf{T} = \frac{dx}{ds}\,\hat{\mathbf{x}} + \frac{dy}{ds}\,\hat{\mathbf{y}} \tag{13}$$

$$\mathbf{N} = -\frac{dy}{ds}\,\hat{\mathbf{x}} + \frac{dx}{ds}\,\hat{\mathbf{y}}, \tag{14}$$

gravity and friction are then

$$\mathbf{F}_{\text{gravity}} = mg\hat{\mathbf{y}} \tag{15}$$

$$\mathbf{F}_{\text{friction}} = -\mu(\mathbf{F}_{\text{gravity}}\dot{\mathbf{N}})\mathbf{T} = -\mu mg\,\frac{dx}{ds}\,\mathbf{T}, \tag{16}$$

and the components along the curve are

$$\mathbf{F}_{\text{gravity}}\dot{\mathbf{T}} = mg\,\frac{dy}{ds} \tag{17}$$

$$\mathbf{F}_{\text{friction}}\dot{\mathbf{T}} = -\mu mg\,\frac{dx}{ds}, \tag{18}$$

so Newton's Second Law gives

$$m\,\frac{dv}{dt} = mg\,\frac{dy}{ds} - \mu mg\,\frac{dx}{ds}. \tag{19}$$

But

$$\frac{dv}{dt} = v\,\frac{dv}{ds} = \frac{1}{2}\,\frac{d}{ds}(v^2) \tag{20}$$

$$\tfrac{1}{2}v^2 = g(y - \mu x) \tag{21}$$

$$v = \sqrt{2g(y - \mu x)}, \tag{22}$$

so

$$t = \int \sqrt{\frac{1+(y')^2}{2g(y-\mu x)}}\,dx. \tag{23}$$

Using the EULER-LAGRANGE DIFFERENTIAL EQUATION gives

$$[1+y'^2](1+\mu y') + 2(y-\mu x)y'' = 0. \tag{24}$$

This can be reduced to

$$\frac{1+(y')^2}{(1+\mu y')^2} = \frac{C}{y-\mu x}. \tag{25}$$

Now letting

$$y' = \cot(\tfrac{1}{2}\theta), \tag{26}$$

the solution is

$$x = \tfrac{1}{2}k^2[(\theta - \sin\theta) + \mu(1 - \cos\theta)] \tag{27}$$

$$y = \tfrac{1}{2}k^2[(1 - \cos\theta) + \mu(\theta - \sin\theta)]. \tag{28}$$

Bracket

Mathematicians often use the term "bracket" to mean "COMMUTATOR," which is denoted using SQUARE BRACKETS.

See also ANGLE BRACKET, BRA, BRACE, BRACKET POLYNOMIAL, BRACKET PRODUCT, IVERSON BRACKET,

KET, LAGRANGE BRACKET, POISSON BRACKET, SQUARE BRACKET

Bracket Polynomial

A one-variable KNOT POLYNOMIAL related to the JONES POLYNOMIAL. The bracket polynomial, however, is *not* a topological invariant, since it is changed by type I REIDEMEISTER MOVES. However, the SPAN of the bracket polynomial is a knot invariant. The bracket polynomial is occasionally given the grandiose name REGULAR ISOTOPY INVARIANT. It is defined by

$$\langle L\rangle(A,\ B,\ d) \equiv \sum_\sigma \langle L|\sigma\rangle d^{\|\sigma\|}, \tag{1}$$

where A and B are the "splitting variables," σ runs through all "states" of L obtained by SPLITTING the LINK, $\langle L|\sigma\rangle$ is the product of "splitting labels" corresponding to σ, and

$$\|\sigma\| \equiv N_L - 1, \tag{2}$$

where N_L is the number of loops in σ. Letting

$$B = A^{-1} \tag{3}$$

$$d = -A^2 - A^{-2} \tag{4}$$

gives a KNOT POLYNOMIAL which is invariant under REGULAR ISOTOPY, and normalizing gives the KAUFFMAN POLYNOMIAL X which is invariant under AMBIENT ISOTOPY. The bracket POLYNOMIAL of the UNKNOT is 1. The bracket POLYNOMIAL of the MIRROR IMAGE K^* is the same as for K but with A replaced by A^{-1}. In terms of the one-variable KAUFFMAN POLYNOMIAL X, the two-variable KAUFFMAN POLYNOMIAL F and the JONES POLYNOMIAL V,

$$X(A) = (-A^3)^{-w(L)}\langle L\rangle, \tag{5}$$

$$\langle L\rangle(A) = F(-A^3,\ A + A^{-1}) \tag{6}$$

$$\langle L\rangle(A) = V(A^{-4}), \tag{7}$$

where $w(L)$ is the WRITHE of L.

Bracket Product

L2-INNER PRODUCT

Bracketing

Take x itself to be a bracketing, then recursively define a bracketing as a sequence $B = (B_1,\ \ldots,\ B_k)$ where $k \geq 2$ and each B_i is a bracketing. A bracketing can be REPRESENTED AS a parenthesized string of xs, with parentheses removed from any single letter x for clarity of notation (Stanley 1997). Bracketings built up of binary operations only are called BINARY BRACKETINGS. For example, four letters have 11 possible bracketings:

$$\begin{array}{cccc} xxxx & (xx)xx & x(xx)x & xx(xx) \\ (xxx)x & x(xxx) & ((xx)x)x & (x(xx))x \\ (xx)(xx) & x((xx)x) & x(x(xx)), & \end{array}$$

the last five of which are binary.

The number of bracketings on n letters is given by the GENERATING FUNCTION

$$\tfrac{1}{4}(1 + x - \sqrt{1 - 6x + x^2}) = x + x^2 + 3x^3 + 11x^4 + 45x^5$$

(Schröder 1870, Stanley 1997) and the RECURRENCE RELATION

$$s_n = \frac{3(2n-3)s_{n-1} - (n-3)s_{n-2}}{n}$$

(Sloane), giving the sequence for s_n as 1, 1, 3, 11, 45, 197, 903, ... (Sloane's A001003). The numbers are also given by

$$s_n = \sum_{i_1 + \ldots + i_k = n} s(i_1)\cdots s(i_k)$$

for $n \geq 2$ (Stanley 1997).

The first PLUTARCH NUMBER 103,049 is equal to s_{10} (Stanley 1997), suggesting that Plutarch's problem of ten compound propositions is equivalent to the number of bracketings. In addition, Plutarch's second number 310,954 is given by $(s_{10} + s_{11})/2 = 310,\ 954$ (Habsieger *et al.* 1998).

Bradley's Theorem

Let

$$S(\alpha, \beta, m; z) \equiv m \sum_{j=0}^{\infty} \frac{\Gamma(m + j(z+1))\Gamma(\beta + 1 + jz)}{\Gamma(m + jz + 1)\Gamma(\alpha + \beta + 1 + j(z+1))} \frac{(\alpha)_j}{j!},$$

where $(\alpha)_j$ is a POCHHAMMER SYMBOL, and let α be a NEGATIVE INTEGER. Then

$$S(\alpha, \beta, m; z) = \frac{\Gamma(\beta + 1 - m)}{\Gamma(\alpha + \beta + 1 - m)},$$

where $\Gamma(z)$ is the GAMMA FUNCTION.

Brahmagupta Identity

Let

$$\beta \equiv \det B = x^2 - ty^2,$$

where B is the BRAHMAGUPTA MATRIX, then

$$\det[B(x_1, y_1)B(x_2, y_2)] = \det[B(x_1, y_1)] \det[B(x_2, y_2)] = \beta_1\beta_2.$$

References

Suryanarayan, E. R. "The Brahmagupta Polynomials." *Fib. Quart.* **34**, 30–39, 1996.

Brahmagupta Matrix

$$B(x, y) = \begin{bmatrix} x & y \\ \pm ty & \pm x \end{bmatrix}.$$

It satisfies

$$B(x_1, y_1)B(x_2, y_2) = B(x_1x_2 \pm ty_1y_2, x_1y_2 \pm y_1x_2).$$

Powers of the matrix are defined by

$$B^n = \begin{bmatrix} x & y \\ ty & x \end{bmatrix}^n = \begin{bmatrix} x_n & y_n \\ ty_n & x_n \end{bmatrix} \equiv B_n.$$

The x_n and y_n are called BRAHMAGUPTA POLYNOMIALS. The Brahmagupta matrices can be extended to NEGATIVE INTEGERS

$$B^{-n} = \begin{bmatrix} x & y \\ ty & x \end{bmatrix}^{-n} = \begin{bmatrix} x_{-n} & y_{-n} \\ ty_{-n} & x_{-n} \end{bmatrix} \equiv B_{-n}.$$

See also BRAHMAGUPTA IDENTITY

References

Suryanarayan, E. R. "The Brahmagupta Polynomials." *Fib. Quart.* **34**, 30–39, 1996.

Brahmagupta Polynomial

One of the POLYNOMIALS obtained by taking POWERS of the BRAHMAGUPTA MATRIX. They satisfy the RECURRENCE RELATION

$$x_{n+1} = xx_n + tyy_n \quad (1)$$

$$y_{n+1} = xy_n + yx_n. \quad (2)$$

A list of many others is given by Suryanarayan (1996). Explicitly,

$$x_n = x^n + t\binom{n}{2}x^{n-2}y^2 + t^2\binom{n}{4}x^{n-4}y^4 + \ldots \quad (3)$$

$$y_n = nx^{n-1}y + t\binom{n}{3}x^{n-3}y^3 + t^2\binom{n}{5}x^{n-5}y^5 + \ldots \quad (4)$$

The Brahmagupta POLYNOMIALS satisfy

$$\frac{\partial x_n}{\partial x} = \frac{\partial y_n}{\partial y} = nx_{n-1} \quad (5)$$

$$\frac{\partial x_n}{\partial y} = t\,\frac{\partial y_n}{\partial y} = nty_{n-1}. \quad (6)$$

The first few POLYNOMIALS are

$$x_0 = 0$$
$$x_1 = x$$
$$x_2 = x^2 + ty^2$$
$$x_3 = x^3 + 3txy^2$$
$$x_4 = x^4 + 6tx^2y^2 + t^2y^4$$

and

$$y_0 = 0$$
$$y_1 = y$$
$$y_2 = 2xy$$
$$y_3 = 3x^2y + ty^3$$
$$y_4 = 4x^3y + 4txy^3.$$

Taking $x = y = 1$ and $t = 2$ gives y_n equal to the PELL NUMBERS and x_n equal to half the Pell-Lucas numbers. The Brahmagupta POLYNOMIALS are related to the MORGAN-VOYCE POLYNOMIALS, but the relationship given by Suryanarayan (1996) is incorrect.

Brahmagupta's Formula

For a QUADRILATERAL with sides of length a, b, c, and d, the AREA K is given by

$$K = \sqrt{(s-a)(s-b)(s-c)(s-d) - abcd\cos^2[\tfrac{1}{2}(A+B)]}, \tag{1}$$

where

$$s \equiv \tfrac{1}{2}(a+b+c+d) \tag{2}$$

is the SEMIPERIMETER, A is the ANGLE between a and d, and B is the ANGLE between b and c. For a CYCLIC QUADRILATERAL (i.e., a QUADRILATERAL inscribed in a CIRCLE), $A+B=\pi$, so

$$K = \sqrt{(s-a)(s-b)(s-c)(s-d)} \tag{3}$$

$$= \frac{\sqrt{(bc+ad)(ac+bd)(ab+cd)}}{4R}, \tag{4}$$

where R is the RADIUS of the CIRCUMCIRCLE. If the QUADRILATERAL is INSCRIBED in one CIRCLE and CIRCUMSCRIBED on another, then the AREA FORMULA simplifies to

$$K = \sqrt{abcd}. \tag{5}$$

Braid Group

Also called ARTIN BRAID GROUPS. Consider n strings, each oriented vertically from a lower to an upper "bar." If this is the least number of strings needed to make a closed braid representation of a LINK, n is called the BRAID INDEX. Now enumerate the possible braids in a group, denoted B_n. A general n-braid is constructed by iteratively applying the σ_i ($i = 1, \ldots, n-1$) operator, which switches the lower endpoints of the ith and $(i+1)$th strings–keeping the upper endpoints fixed–with the $(i+1)$th string brought *above* the ith string. If the $(i+1)$th string passes *below* the ith string, it is denoted σ_i^{-1}.

Topological equivalence for different representations of a BRAID WORD $\Pi_i \sigma_i$ and $\Pi_i \sigma_i'$ is guaranteed by the conditions

$$\begin{cases} \sigma_i \sigma_j = \sigma_j \sigma_i & \text{for } |i-j| \geq 2 \\ \sigma_i \sigma_{i+1} \sigma_i = \sigma_{i+1} \sigma_i \sigma_{i+1} & \text{for all } i \end{cases}$$

as first proved by E. Artin. Any n-braid is expressed as a BRAID WORD, e.g., $\sigma_1 \sigma_2 \sigma_3 \sigma_2^{-1} \sigma_1$ is a BRAID WORD for the braid group B_3. When the opposite ends of the braids are connected by nonintersecting lines, KNOTS are formed which are identified by their braid group and BRAID WORD. The BURAU REPRESENTATION gives a matrix representation of the braid groups.

Braid Index

The least number of strings needed to make a closed braid representation of a LINK. The braid index is equal to the least number of SEIFERT CIRCLES in any projection of a KNOT (Yamada 1987). Also, for a nonsplittable LINK with CROSSING NUMBER $c(L)$ and braid index $i(L)$,

$$c(L) \geq 2[i(L) - 1]$$

(Ohyama 1993). Let E be the largest and e the smallest POWER of ℓ in the HOMFLY POLYNOMIAL of an oriented LINK, and i be the braid index. Then the MORTON-FRANKS-WILLIAMS INEQUALITY holds,

$$i \geq \tfrac{1}{2}(E - e) + 1$$

(Franks and Williams 1987). The inequality is sharp for all PRIME KNOTS up to 10 crossings with the exceptions of 09–042, 09–049, 10–132, 10–150, and 10–156.

Braid Word

Any n-braid is expressed as a braid word, e.g., $\sigma_1 \sigma_2 \sigma_3 \sigma_2^{-1} \sigma_1$ is a braid word for the BRAID GROUP B_3. By ALEXANDER'S THEOREM, any LINK is representable by a closed braid, but there is no general procedure for reducing a braid word to its simplest form. However, MARKOV'S THEOREM gives a procedure for identifying different braid words which represent the same LINK.

Let b_+ be the sum of POSITIVE exponents, and b_- the sum of NEGATIVE exponents in the BRAID GROUP B_n. If

$$b_+ - 3b_- \geq n,$$

then the closed braid b is not AMPHICHIRAL (Jones 1985).

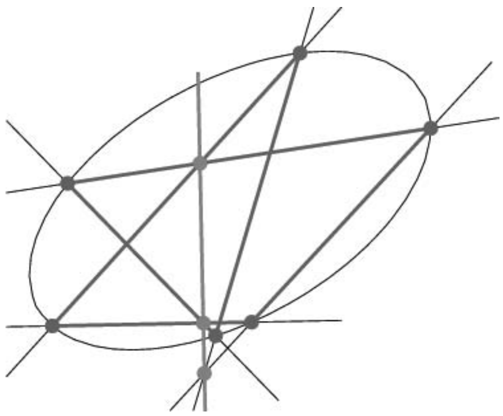
Braikenridge-Maclaurin Construction



Let A_n, B_2, C_1, A_2, and B_1 be five points determining a CONIC. Then the CONIC is the LOCUS of the point

$$C_2 = A_1(L \cdot C_1A_2) \cdot B_1(L \cdot C_1B_2),$$

where L is a line through the point $A_1B_2 \cdot B_1A_2$.

See also BRAIKENRIDGE-MACLAURIN THEOREM, CONIC SECTION

Braikenridge-Maclaurin Theorem

The converse of PASCAL'S THEOREM, which states that if the three pairs of opposite sides of (an irregular) HEXAGON meet at three COLLINEAR points, then the six vertices lie on a conic, which may degenerate into a pair of lines (Coxeter and Greitzer 1967, p. 76).

Branch Cut

A line in the COMPLEX PLANE across which a MULTIVALUED FUNCTION is discontinuous. Some functions have a relatively simple branch cut structure, but branch cuts for some functions are extremely complicated. The illustrations above show the single branch cut present in the definition of the square root function in the complex plane. In general, branch cuts are not unique, but are chosen by convention to give simple analytic properties. An alternative to branch cuts is the use of RIEMANN SURFACES.

function	branch cut(s)
$\cos^{-1} z$	$(-\infty, -1)$ and $(1, \infty)$
$\cosh^{-1}$	$(-\infty, 1)$
$\cot^{-1} z$	$(-i, i)$
$\coth^{-1}$	$[-1, 1]$
$\csc^{-1} z$	$(-1, 1)$
csch^{-1}	$(-i, i)$
$\ln z$	$(-\infty, 0]$
$\sec^{-1} z$	$(-1, 1)$
sech^{-1}	$(\infty, 0]$ and $(1, \infty)$
$\sin^{-1} z$	$(-\infty, -1)$ and $(1, \infty)$
$\sinh^{-1}$	$(-i\infty, -i)$ and $(i, i\infty)$
$\sqrt{z}$	$(-\infty, 0)$
$\tan^{-1} z$	$(-i\infty, -i)$ and $(i, i\infty)$
$\tanh^{-1}$	$(-\infty, -1]$ and $[1, \infty)$
z^n, $n \notin \mathbb{Z}$	$(-\infty, 0)$ for $\Re[n] \leq 0$; $(-\infty, 0]$ for $\Re[n] > 0$

Branch Line

BRANCH CUT

Branch Point

An argument at which identical points in the COMPLEX PLANE are mapped to different points. For example, consider

$$f(z) = z^a.$$

Then $f(e^{0i}) = f(1) = 1$, but $f(e^{2\pi i}) = e^{2\pi ia}$, despite the fact that $e^{i0} = e^{2\pi i}$. PINCH POINTS are also called branch points.

Brauer-Severi Variety

An ALGEBRAIC VARIETY over a FIELD K that becomes ISOMORPHIC to a PROJECTIVE SPACE.

References

Hazewinkel, M. (Managing Ed.). *Encyclopaedia of Mathematics: An Updated and Annotated Translation of the Soviet "Mathematical Encyclopaedia."* Dordrecht, Netherlands: Reidel, pp. 480–481, 1988.

Braun's Conjecture

Let $B = \{b_1, b_2, \ldots\}$ be an INFINITE ABELIAN SEMIGROUP with linear order $b_1 < b_2 < \ldots$ such that b_1 is the unit element and $a < b$ IMPLIES $ac < bc$ for $a, b, c \in B$. Define a MÖBIUS FUNCTION μ on B by $\mu(b_1) = 1$ and

$$\sum_{b_d | b_n} \mu(b_d) = 0$$

for $n = 2, 3, \ldots$. Further suppose that $\mu(b_n) = \mu(n)$ (the true MÖBIUS FUNCTION) for all $n \geq 1$. Then Braun's conjecture states that

$$b_{mn} = b_m \, b_n$$

for all $m, n \geq 1$.

Breeder

A pair of POSITIVE INTEGERS (a_1, a_2) such that the equations

$$a_1 + a_2 x = \sigma(a_1) = \sigma(a_2)(x+1)$$

have a POSITIVE INTEGER solution x, where $\sigma(n)$ is the DIVISOR FUNCTION. If x is PRIME, then $(a_1, a_2 x)$ is an AMICABLE PAIR (te Riele 1986). (a_1, a_2) is a "special" breeder if

$$a_1 = au$$

$$a_2 = a,$$

where a and u are RELATIVELY PRIME, $(a, u) = 1$. If regular amicable pairs of type $(i, 1)$ with $i \geq 2$ are OF THE FORM (au, ap) with p PRIME, then (au, a) are special breeders (te Riele 1986).

Brent's Factorization Method

A modification of the POLLARD RHO FACTORIZATION METHOD which uses

$$x_{i+1} = x_i^2 - c \pmod{n}.$$

References

Brent, R. "An Improved Monte Carlo Factorization Algorithm." *Nordisk Tidskrift for Informationsbehandlung (BIT)* **20**, 176–184, 1980.

Brent's Method

A ROOT-finding ALGORITHM which combines root bracketing, bisection, and INVERSE QUADRATIC INTERPOLATION. It is sometimes known as the VAN WIJNGAARDEN-DEKER-BRENT METHOD.

Brent's method uses a LAGRANGE INTERPOLATING POLYNOMIAL of degree 2. Brent (1973) claims that this method will always converge as long as the values of the function are computable within a given region containing a ROOT. Given three points x_1, x_2, and x_3, Brent's method fits x as a quadratic function of y, then uses the interpolation formula

$$x = \frac{[y - f(x_1)][y - f(x_2)]x_3}{[f(x_3) - f(x_1)][f(x_3) - f(x_2)]} + \frac{[y - f(x_2)][y - f(x_3)]x_1}{[f(x_1) - f(x_2)][f(x_1) - f(x_3)]} + \frac{[y - f(x_3)][y - f(x_1)]x_2}{[f(x_2) - f(x_3)][f(x_2) - f(x_1)]}. \quad (1)$$

Subsequent root estimates are obtained by setting $y = 0$, giving

$$x = x_2 + \frac{P}{Q}, \quad (2)$$

where

$$P = S[R(R-T)(x_3 - x_2) - (1-R)(x_2 - x_1)] \quad (3)$$

$$Q = (T-1)(R-1)(S-1) \quad (4)$$

with

$$R \equiv \frac{f(x_2)}{f(x_3)} \quad (5)$$

$$S \equiv \frac{f(x_2)}{f(x_1)} \quad (6)$$

$$T \equiv \frac{f(x_1)}{f(x_3)} \quad (7)$$

(Press *et al.* 1992).

Brent-Salamin Formula

A formula which uses the ARITHMETIC-GEOMETRIC MEAN to compute PI. It has quadratic convergence and is also called the GAUSS-SALAMIN FORMULA and SALAMIN FORMULA. Let

$$a_{n+1} = \tfrac{1}{2}(a_n + b_n) \quad (1)$$

$$b_{n+1} = \sqrt{a_n b_n} \quad (2)$$

$$c_{n+1} = \tfrac{1}{2}(a_n - b_n) \quad (3)$$

$$d_n \equiv a_n^2 - b_n^2, \quad (4)$$

and define the initial conditions to be $a_0 = 1$, $b_0 = 1/\sqrt{2}$. Then iterating a_π and b_n gives the ARITHMETIC-

GEOMETRIC MEAN, and π is given by

$$\pi = \frac{4[M(1,\ 2^{-1/2})]^2}{1 - \sum_{j=1}^{\infty} 2^{j+1} d_j} \tag{5}$$

$$= \frac{4[M(1,\ 2^{-1/2})]^2}{1 - \sum_{j=1}^{\infty} 2^{j+1} c_j^2}. \tag{6}$$

King (1924) showed that this formula and the LEGENDRE RELATION are equivalent and that either may be derived from the other.

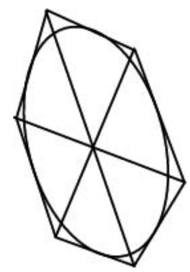
Brianchon Point

The point of CONCURRENCE of the joins of the VERTICES of a TRIANGLE and the points of contact of a CONIC SECTION INSCRIBED in the TRIANGLE. A CONIC INSCRIBED in a TRIANGLE has an equation OF THE FORM

$$\frac{f}{u} + \frac{g}{v} + \frac{h}{w} = 0,$$

so its Brianchon point has TRILINEAR COORDINATES $(1/f,\ 1/g,\ 1/h)$. For KIEPERT'S PARABOLA, the Branchion point has TRIANGLE CENTER FUNCTION

$$\alpha = \frac{1}{a(b^2 - c^2)},$$



which is the STEINER POINT.

Bridge

The bridges of a CONNECTED GRAPH are the EDGES whose removal disconnects the GRAPH (Chartrand 1985, p. 45; Skiena 1990, p. 177). More generally, a bridge is an edge of a GRAPH G whose removal increases the number of components of G (Harary 1994, p. 26). An edge of a CONNECTED GRAPH is a bridge IFF is does not lie on any cycle. The bridges of a graph can be found using `Bridges[g]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).
Every edge of a TREE is a bridge. A CUBIC GRAPH contains a bridge IFF it contains an ARTICULATION VERTEX (Skiena 1990, p. 177).

See also ARTICULATION VERTEX, BLOCK

Bridge Card Game

Bridge is a CARD game played with a normal deck of 52 cards. The number of possible distinct 13-card hands is

$$N = \binom{52}{13} = 635,013,559,600.$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT. While the chances of being dealt a hand of 13 CARDS (out of 52) of the same suit are

$$\frac{4}{\binom{52}{13}} = \frac{1}{158,753,389,900},$$

the chance that one of four players will receive a hand of a single suit is

$$\frac{1}{39,688,347,497}.$$

There are special names for specific types of hands. A ten, jack, queen, king, or ace is called an "honor." Getting the three top cards (ace, king, and queen) of three suits and the ace, king, and queen, and jack of the remaining suit is called 13 top honors. Getting all cards of the same suit is called a 13-card suit. Getting 12 cards of same suit with ace high and the 13th card *not* an ace is called 2-card suit, ace high. Getting *no* honors is called a Yarborough.

The probabilities of being dealt 13-card bridge hands of a given type are given below. As usual, for a hand with probability P, the ODDS against being dealt it are $(1/P) - 1 : 1$.

Hand	Exact Probability	Probability	ODDS
13 top honors	$\frac{4}{N} = \frac{1}{158,753,389,900}$	6.30×10^{-12}	158,753,389,899:1
13-card suit	$\frac{4}{N} = \frac{1}{158,753,389,900}$	6.30×10^{-12}	158,753,389,899:1
12-card suit, ace high	$\frac{4 \cdot 12 \cdot 36}{N} = \frac{4}{1,469,938,705}$	2.72×10^{-9}	367,484,697.8:1
Yarborough	$\frac{\binom{32}{13}}{N} = \frac{5,394}{9,860,459}$	5.47×10^{-4}	1,827.0:1
four aces	$\frac{\binom{48}{9}}{N} = \frac{11}{4,165}$	2.64×10^{-3}	377.6:1
nine honors	$\frac{\binom{20}{9}\binom{32}{4}}{N} = \frac{888,212}{93,384,347}$	9.51×10^{-3}	104.1:1

Bridge Knot

An n-bridge knot is a knot with BRIDGE NUMBER n. The set of 2-bridge knots is identical to the set of rational knots. If L is a 2-BRIDGE KNOT, then the BLM/HO POLYNOMIAL Q and JONES POLYNOMIAL V satisfy

$$Q_L(z) = 2z^{-1}V_L(t)V_L(t^{-1}+1-2z^{-1}),$$

where $z \equiv -t-t^{-1}$ (Kanenobu and Sumi 1993). Kanenobu and Sumi also give a table containing the number of distinct 2-bridge knots of n crossings for $n = 10$ to 22, both not counting and counting MIRROR IMAGES as distinct.

Bridge Number

The least number of unknotted arcs lying above the plane in any projection. The knot 05–002 has bridge number 2. Such knots are called 2-BRIDGE KNOTS. There is a one-to-one correspondence between 2-BRIDGE KNOTS and rational knots. The knot 08–010 is a 3-bridge knot. A knot with bridge number b is an n-EMBEDDABLE KNOT where $n \leq b$.

Bring-Jerrard Quintic Form

A TSCHIRNHAUSEN TRANSFORMATION can be used to algebraically transform a general QUINTIC EQUATION to the form

$$z^5 + c_1 z + c_0 = 0. \tag{1}$$

In practice, the general quintic is first reduced to the PRINCIPAL QUINTIC FORM

$$y^5 + b_2 y^2 + b_1 y + b_0 = 0 \tag{2}$$

before the transformation is done. Then, we require that the sum of the third POWERS of the ROOTS vanishes, so $s_3(y_j) = 0$. We assume that the ROOTS z_i of the Bring-Jerrard quintic are related to the ROOTS y_i of the PRINCIPAL QUINTIC FORM by

$$z_i = \alpha y_i^4 + \beta y_i^3 + \gamma y_i^2 + \delta y_i + \epsilon. \tag{3}$$

In a similar manner to the PRINCIPAL QUINTIC FORM transformation, we can express the COEFFICIENTS c_j in terms of the b_j.

Brioschi Formula

For a curve with METRIC

$$ds^2 = E\,du^2 + F\,du\,dv + G\,dv^2, \tag{1}$$

where E, F, and G is the first FUNDAMENTAL FORM, the GAUSSIAN CURVATURE is

$$K = \frac{M_1 + M_2}{(EG - F^2)^2}, \tag{2}$$

where

$$M_1 \equiv \begin{vmatrix} -\tfrac{1}{2}E_{uv} + F_{uv} - \tfrac{1}{2}G_{uu} & \tfrac{1}{2}E_u & F_u - \tfrac{1}{2}E_v \\ F_v - \tfrac{1}{2}G_u & E & F \\ \tfrac{1}{2}G_v & F & G \end{vmatrix} \tag{3}$$

$$M_2 \equiv \begin{vmatrix} 0 & \tfrac{1}{2}E_v & \tfrac{1}{2}G_u \\ \tfrac{1}{2}E_v & E & F \\ \tfrac{1}{2}G_u & F & G \end{vmatrix}, \tag{4}$$

which can also be written

$$K = -\frac{1}{\sqrt{EG}}\left[\frac{\partial}{\partial u}\left(\frac{1}{\sqrt{E}}\frac{\partial\sqrt{G}}{\partial u}\right) + \frac{\partial}{\partial v}\left(\frac{1}{\sqrt{G}}\frac{\partial\sqrt{E}}{\partial v}\right)\right] \tag{5}$$

$$= -\frac{1}{\sqrt{EG}}\left[\frac{\partial}{\partial u}\left(\frac{G_u}{\sqrt{EG}}\right) + \frac{\partial}{\partial v}\left(\frac{E_v}{\sqrt{EG}}\right)\right]. \tag{6}$$

Briot-Bouquet Equation

An ORDINARY DIFFERENTIAL EQUATION OF THE FORM

$$x^m y' = f(x,\ y),$$

where m is a POSITIVE INTEGER, f is ANALYTIC at $x = y = 0$, $f(0,\ 0) = 0$, and $f'_y(0,\ 0) \neq 0$.

Zwillinger (1997, p. 120), citing Ince (1956, p. 295), define the Briot-Bouquet equation as

$$xy' - \lambda y = a_{10}x + a_{20}x^2 + a_{11}yx + a_{02}y^2 + \cdots$$

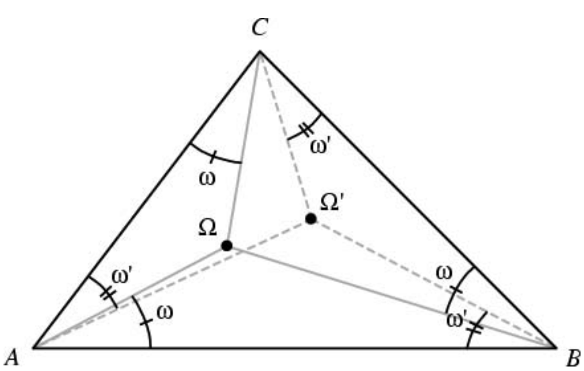
Brjuno Number

Let p_n/q_n be the sequence of CONVERGENTS of the CONTINUED FRACTION of a number α. Then a Brjuno number is an IRRATIONAL NUMBER such that

$$\sum_{n=0}^{\infty} \frac{\ln q_{n+1}}{q_n} < \infty$$



(Marmi *et al.* 1999). Brjuno numbers arise in the study of one-dimensional analytic small divisors problems, and Brjuno (1971, 1972) proved that all "germs" with linear part $\lambda = e^{2\pi i\alpha}$ are linearizable if α is a Brjuno number. Yoccoz (1995) proved that this condition is also NECESSARY.

GOSSIPING

Brocard Angle

Define the first BROCARD POINT as the interior point Ω of a TRIANGLE for which the ANGLES $\angle\ \Omega AB$, $\angle\ \Omega BC$, and $\angle\ \Omega CA$ are equal to an angle ω. Similarly, define the second BROCARD POINT as the interior point Ω' for which the ANGLES $\angle\ \Omega' AC$, $\angle\ \Omega' CB$, and $\angle\ \Omega' BA$ are equal to an angle ω'. Then $\omega = \omega'$, and this angle is called the Brocard angle.

The Brocard angle ω of a TRIANGLE $\Delta A_1 A_2 A_3$ is given by the formulas

$$\cot\omega = \cot A_1 + \cot A_2 + \cot A_3 \tag{1}$$

$$= \left(\frac{a_1^2 + a_2^2 + a_3^2}{4\Delta}\right) \tag{2}$$

$$= \frac{1 + \cos\alpha_1 \cos\alpha_2 \cos\alpha_3}{\sin\alpha_1 \sin\alpha_2 \sin\alpha_3} \tag{3}$$

$$= \frac{\sin^2\alpha_1 + \sin^2\alpha_2 + \sin^2\alpha_3}{2\sin\alpha_1 \sin\alpha_2 \sin\alpha_3} \tag{4}$$

$$= \frac{a_1 \sin\alpha_1 + a_2 \sin\alpha_2 + a_3 \sin\alpha_3}{a_1 \cos\alpha_1 + a_2 \cos\alpha_2 + a_3 \cos\alpha_3} \tag{5}$$

$$\csc^2\omega = \csc^2\alpha_1 + \csc^2\alpha_2 + \csc^2\alpha_3 \tag{6}$$

$$\sin\omega = \frac{2\Delta}{\sqrt{a_1^2 a_2^2 + a_2^2 a_3^2 + a_3^2 a_1^2}} \tag{7}$$

where Δ is the TRIANGLE AREA, A, B, and C are ANGLES, and a, b, and c are side lengths (Johnson 1929), where (6) is due to Neuberg (Tucker 1883).

If an ANGLE α of a TRIANGLE is given, the maximum possible Brocard angle is given by

$$\cot\omega = \tfrac{3}{2}\tan(\tfrac{1}{2}\alpha) + \tfrac{1}{2}\cos(\tfrac{1}{2}\alpha) \tag{8}$$

(Johnson 1929, p. 289). If ω is specified, that the largest possible value $\alpha_{\max}$ and minimum possible value $\alpha_{\min}$ of any possible triangle having Brocard angle ω are given by

$$\cot(\tfrac{1}{2}\alpha_{\max}) = \cot\omega - \sqrt{\cot^2 - 3} \tag{9}$$

$$\cot(\tfrac{1}{2}\alpha_{\min}) = \cot\omega + \sqrt{\cot^2 - 3}, \tag{10}$$

where the square rooted quantity is the radius of the corresponding NEUBERG CIRCLE (Johnson 1929, p. 288). The maximum possible Brocard angle for any triangle is 30° (Honsberger 1995, pp. 102–103).

Let a TRIANGLE have ANGLES A, B, and C. Then

$$\sin A \sin B \sin C \le kABC, \tag{11}$$

where

$$k = \left(\frac{3\sqrt{3}}{2\pi}\right)^3 \tag{12}$$

(Le Lionnais 1983). This can be used to prove that

$$8\omega^3 < ABC \tag{13}$$

(Abi-Khuzam 1974).

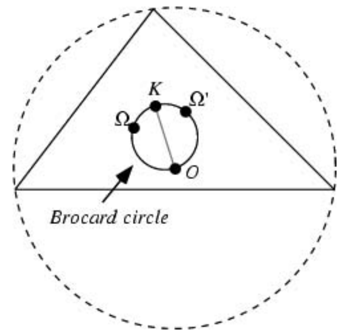
Brocard Axis

The LINE KO passing through the SYMMEDIAN POINT K and CIRCUMCENTER O of a TRIANGLE. The distance $\overline{OK}$ is called the BROCARD DIAMETER. The Brocard axis is PERPENDICULAR to the LEMOINE AXIS and is the ISOGONAL CONJUGATE of KIEPERT'S HYPERBOLA. It has equations

$$\sin(B-C)\alpha+\sin(C-A)\beta+\sin(A-B)\gamma=0$$



$$bc(b^2-c^2)\alpha+ca(c^2-a^2)\beta+ab(a^2-b^2)\gamma=0.$$

The SYMMEDIAN POINT K, CIRCUMCENTER O, ISODYNAMIC POINTS S and S', and BROCARD MIDPOINT M_B all lie along the Brocard axis.

Note that the Brocard axis is *not* equivalent to the BROCARD LINE.

See also BROCARD CIRCLE, BROCARD DIAMETER, BROCARD LINE

Brocard Circle

The CIRCLE passing through the first and second BROCARD POINTS Ω and Ω', the LEMOINE POINT K, and the CIRCUMCENTER O of a given TRIANGLE. The BROCARD POINTS Ω and Ω' are symmetrical about the LINE $\overleftrightarrow{KO}$, which is called the BROCARD LINE. The LINE SEGMENT $\overline{KO}$ is called the BROCARD DIAMETER, and it has length

$$\overline{OK}=\frac{\overline{O\Omega}}{\cos\omega}=\frac{R\sqrt{1-4\sin^2\omega}}{\cos\omega},$$

where R is the CIRCUMRADIUS and ω is the BROCARD ANGLE. The distance between either of the BROCARD POINTS and the SYMMEDIAN POINT is

$$\overline{\Omega K}=\overline{\Omega' K}=\overline{\Omega O}\tan\omega.$$

The Brocard circle and LEMOINE CIRCLE are concentric.

See also BROCARD ANGLE, BROCARD DIAMETER, BROCARD POINTS

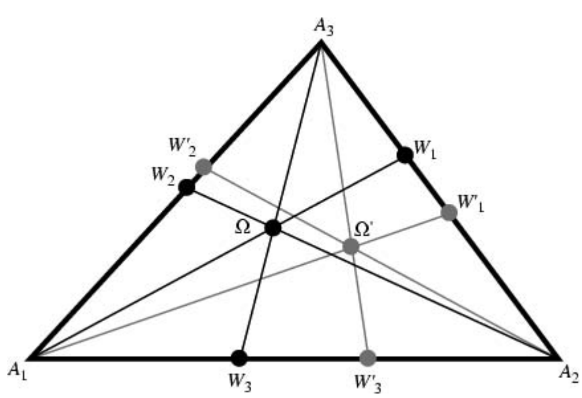
Brocard Diameter



The LINE SEGMENT $\overline{KO}$ joining the SYMMEDIAN POINT K and CIRCUMCENTER O of a given TRIANGLE. It is the DIAMETER of the TRIANGLE'S BROCARD CIRCLE, and lies along the BROCARD AXIS. The Brocard diameter has length

$$\overline{OK} = \frac{\overline{O\Omega}}{\cos\omega} = \frac{R\sqrt{1-4\sin^2\omega}}{\cos\omega},$$

where Ω is the first BROCARD POINT, R is the CIRCUMRADIUS, and ω is the BROCARD ANGLE.

See also BROCARD AXIS, BROCARD CIRCLE, BROCARD LINE, BROCARD POINTS

Brocard Line

A LINE from any of the VERTICES A_i of a TRIANGLE to the first Ω or second Ω' BROCARD POINT. Let the ANGLE at a VERTEX A_i also be denoted A_i, and denote the intersections of $A_1\Omega$ and $A_1\Omega'$ with A_2A_3 as W_1 and W_2. Then the ANGLES involving these points are

$$\angle A_1\Omega W_3 = A_1 \tag{1}$$

$$\angle W_3\Omega A_2 = A_3 \tag{2}$$

$$\angle A_2\Omega W_1 = A_2 \tag{3}$$

Distances involving the points W_i and W_i' are given by

$$\overline{A_2\Omega} = \frac{a_3}{\sin A_2}\sin\omega \tag{4}$$

$$\frac{\overline{A_2\Omega}}{\overline{A_3\Omega}} = \frac{a_3^2}{a_1a_2} = \frac{\sin(A_3-\omega)}{\sin\omega} \tag{5}$$

$$\frac{\overline{W_3A_1}}{\overline{W_3A_2}} = \frac{a_2\sin\omega}{a_1\sin(A_3-\omega)} = \left(\frac{a_2}{a_3}\right)^2, \tag{6}$$

where ω is the BROCARD ANGLE (Johnson 1929, pp. 267–268).

The Brocard line, MEDIAN M, and SYMMEDIAN POINT K are concurrent, with $A_1\Omega_1$, A_2K, and A_3M meeting at a point P. Similarly, $A_1\Omega'$, A_2M, and A_3K meet at a point which is the ISOGONAL CONJUGATE point of P (Johnson 1929, pp. 268–269).

See also BROCARD AXIS, BROCARD DIAMETER, BROCARD POINTS, ISOGONAL CONJUGATE, SYMMEDIAN POINT, MEDIAN (TRIANGLE)

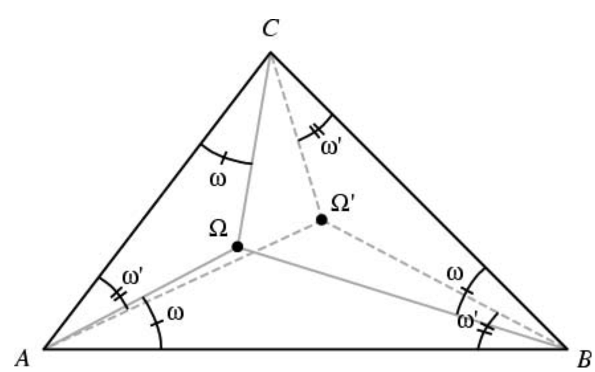
Brocard Midpoint

The MIDPOINT of the BROCARD POINTS. It has TRIANGLE CENTER FUNCTION



$$\alpha = a(b^2+c^2) = \sin(A+\omega),$$

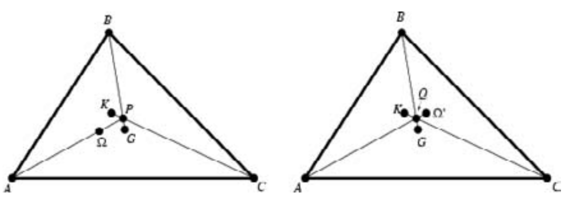
where ω is the BROCARD ANGLE. It lies on the BROCARD AXIS.

References

Kimberling, C. "Central Points and Central Lines in the Plane of a Triangle." *Math. Mag.* **67**, 163–187, 1994.

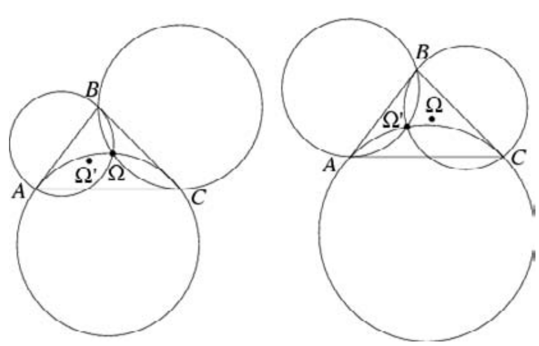
Brocard Points

The first Brocard point is the interior point Ω (or τ_1 or



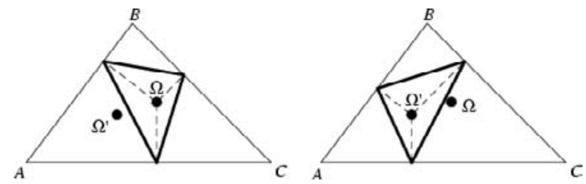
Z_1) of a triangle for which the angles $\angle \Omega AB$, $\angle \Omega BC$, and $\angle \Omega CA$ are equal to an angle ω. The second Brocard point is the interior point Ω' (or τ_2 or Z_2) for which the angles $\angle \Omega' AC$, $\angle \Omega' CB$, and $\angle \Omega' BA$ are equal to an angle ω'. The two angles $\omega = \omega'$ are equal, and this angle is called the Brocard angle,

$$\omega = \angle \Omega AB = \angle \Omega BC = \angle \Omega CA$$



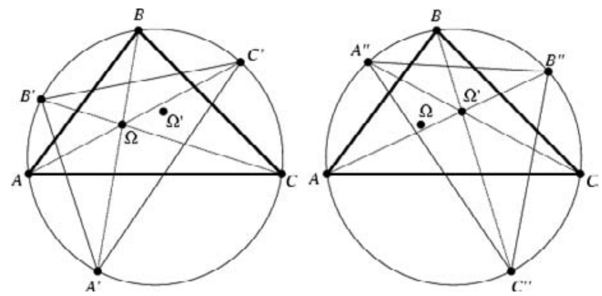
$$= \angle \Omega' AC = \angle \Omega' CB = \angle \Omega' BA.$$

The first two Brocard points are isogonal conjugates (Johnson 1929, p. 266). They were described by French army officer Henri Brocard in 1875, although they had previously been investigated by Jacobi and, in 1816, Crelle (Wells 1991; Honsberger 1995, p. 98). The satisfy $\Omega O = \Omega' O$ and $\angle \Omega O \Omega' = 2\omega$, where O is the circumcenter and ω is the Brocard angle (Honsberger 1995, p. 106).



If three dogs start at the vertices of a triangle and chase either their left or right neighbor at a constant speed, that the three will meet at either Ω or Ω' (Wells 1991).

One Brocard line, median, and symmedian (out of the three of each) are concurrent, with $A\Omega$, CK, and BG meeting at a point, where G is the centroid and K is the symmedian point. Similarly, $A\Omega'$, BG, and CK meet at a point which is the isogonal conjugate of the first (Johnson 1929, pp. 268–269; Honsberger 1995, pp. 121–124).



Let C_{BC} be the circle which passes through the vertices B and C and is tangent to the line AC at C, and similarly for C_{AB} and C_{BC}. Then the circles C_{AB}, C_{BC}, and C_{AC} intersect in the first Brocard point Ω. Similarly, let C'_{BC} be the circle which passes through the vertices B and C and is tangent to the line AB at B, and similarly for C'_{AB} and C'_{AC}. Then the circles C'_{AB}, C'_{BC}, and C'_{AC} intersect in the second Brocard points Ω' (Johnson 1929, pp. 264–265; Honsberger 1995, pp. 99–100).

The pedal triangles of Ω and Ω' are congruent, and similar to the triangle ΔABC (Johnson 1929, p. 269). Lengths involving the Brocard points include

$$\overline{O\Omega} = \overline{O\Omega'} = R\sqrt{1 - 4\sin^2\omega} \tag{1}$$

$$\overline{\Omega\Omega'} = 2R\sin\omega\sqrt{1 - 4\sin^2\omega}. \tag{2}$$

Extend the segments $A\Omega$, $B\Omega$, and $C\Omega$ to the circumcircle of ΔABC to form $\Delta C'A'B'$, and the segments $A\Omega'$, $B\Omega'$, and $C\Omega'$ to form $\Delta B''C''A''$. Then $\Delta A'B'C'$ and $\Delta A''B''C''$ are congruent to ΔABC (Honsberger 1995, pp. 104–106).

Brocard's third point is related to a given triangle by the triangle center function

$$\alpha = a^{-3} \tag{3}$$

(Casey 1893, Kimberling 1994). The third Brocard point Ω'' (or τ_3 or Z_3) is collinear with the Spieker center and the isotomic conjugate point of its triangle's incenter.

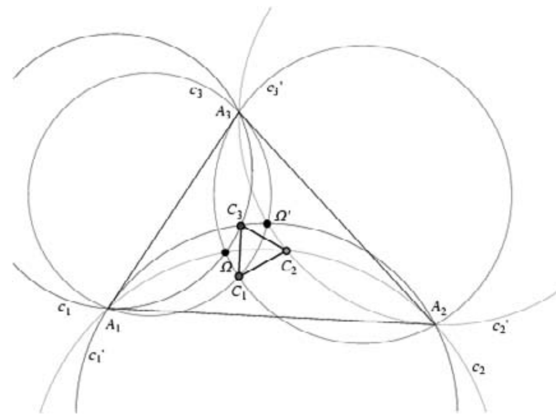
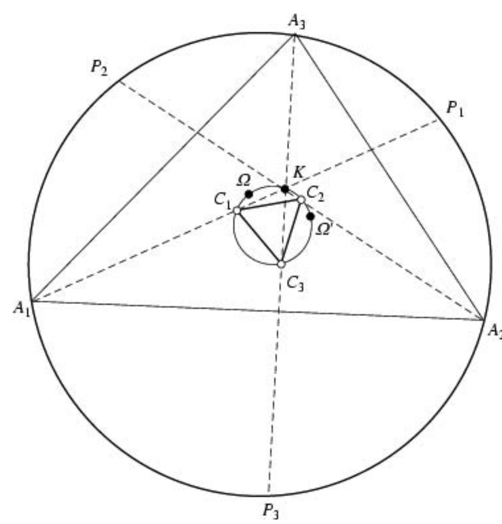
Brocard Triangles



Given TRIANGLE $\Delta A_1A_2A_3$, let the point of intersection of $A_2\Omega$ and $A_3\Omega'$ be B_1, where Ω and Ω' are the BROCARD POINTS, and similarly define B_2 and B_3. Then $B_1B_2B_3$ is called the first Brocard triangle, and is INVERSELY SIMILAR to $A_1A_2A_3$ (Honsberger 1995, p. 112). It is inscribed in the BROCARD CIRCLE drawn with OK as the DIAMETER.



The triangles $B_1A_2A_3$, $B_2A_3A_1$, and $B_3A_1A_2$ are ISOSCELES TRIANGLES with base angles ω, where ω is the BROCARD ANGLE. The sum of the areas of the ISOSCELES TRIANGLES is Δ, the AREA of TRIANGLE $A_1A_2A_3$. The first Brocard triangle is in perspective with the given TRIANGLE, with A_1B_1, A_2B_2, and A_3B_3 CONCURRENT. The CENTROID of the first brocard triangle is the CENTROID G of the original triangle (Honsberger 1995, pp. 112–116).

Let perpendiculars be drawn from the midpoints M_A, M_B, and M_C of each side of the first Brocard triangle to the opposite sides of the triangle ΔABC. Then the extensions of these lines CONCUR in the NINE-POINT CENTER (Honsberger 1995, pp. 116–118).

Let c_1, c_2, and c_3 be the CIRCLES through the vertices A_2 and A_3, A_n and A_3, and A_n and A_2, respectively, which intersect in the first BROCARD POINT Ω. Similarly, define c_1', c_2', and c_3' with respect to the second BROCARD POINT Ω'. Let the two circles c_1 and c_1' tangent at A_n to A_1A_2 and A_1A_3, and passing respectively through A_3 and A_2, meet again at C_1, and similarly for C_2 and C_3. Then the triangle $\Delta C_1C_2C_3$ is called the second Brocard triangle.

The second Brocard triangle is also the triangle obtained as the intersections of the lines A_1K, A_2K, and A_3K with the BROCARD CIRCLE, where K is the SYMMEDIAN POINT. Let P_1, P_2, and P_3 be the intersections of the lines A_1K, A_2K, and A_3K with the CIRCUMCIRCLE of $\Delta A_1A_2A_3$. Then C_1, C_2, and C_3 are the midpoints of A_1P_1, A_2P_2, and A_3P_3, respectively (Lachlan 1893).

The two Brocard triangles are in PERSPECTIVE at M.

Brocard's Conjecture

$$\pi(p_{n+1}^2) - \pi(p_n^2) \geq 4$$

for $n \geq 2$ where $\pi(n)$ is the PRIME COUNTING FUNCTION and p_n is the nth PRIME. For $n = 1, 2, ...$, the first few values are 2, 5, 6, 15, 9, 22, 11, 27, 47, 16, ... (Sloane's A050216).

Brocard's Problem

Find the values of n for which $n!+1$ is a SQUARE NUMBER m^2, where $n!$ is the FACTORIAL (Brocard 1876, 1885). Pairs of numbers (m, n) are called BROWN NUMBERS. The only known solutions are $n = 4$, 5, and 7, and there are no other solutions with $n \leq 10^7$ (Wells 1986, p. 70; D. Wilson). It is virtually certain that there are no more solutions (Guy 1994). In fact, Dabrowski (1996) has shown that $n! + A = k^2$ has only finitely many solutions for general A, although this result requires assumption of a weak form of the ABC CONJECTURE if A is SQUARE).

Wilson has also computed the least k such that $n! + k^2$ is square starting at $n=4$, giving 1, 1, 3, 1, 9, 27, 15, 18, 288, 288, 420, 464, 1856, ... (Sloane's A038202).

Browkin's Theorem

For every POSITIVE INTEGER n, there exists a SQUARE in the plane with exactly n LATTICE POINTS in its interior. This was extended by Schinzel and Kulikowski to *all* plane figures of a given shape. The generalization of the SQUARE in 2-D to the CUBE in 3-D was also proved by Browkin.

Brown Function

For a FRACTAL PROCESS with values $y(t - \Delta t)$ and $y(t + \Delta t)$, the correlation between these two values is given by the Brown function

$$r = 2^{2H-1} - 1,$$

also known as the BACHELIER FUNCTION, LÉVY FUNCTION, or WIENER FUNCTION.

Brown Numbers

Brown numbers are PAIRS (m, n) of INTEGERS satisfying the condition of BROCARD'S PROBLEM, i.e., such that

$$n! + 1 = m^2$$

where $n!$ is the FACTORIAL and m^2 is a SQUARE NUMBER. Only three such PAIRS of numbers are known: (5, 4), (11, 5), (71, 7), and Erdos conjectured that these are the only three such PAIRS.

Brown's Criterion

A SEQUENCE $\{\nu_i\}$ of nondecreasing POSITIVE INTEGERS is COMPLETE IFF

1. $\nu_1 = 1$.
2. For all $k = 2, 3, \ldots,$

$$s_{k-1} = \nu_1 + \nu_2 + \cdots + \nu_{k-1} \geq \nu_k - 1.$$

A corollary states that a SEQUENCE for which $\nu_1 = 1$ and $\nu_{k+1} \leq 2\nu_k$ is COMPLETE (Honsberger 1985).

Bruck-Ryser Theorem

BRUCK-RYSER-CHOWLA THEOREM

Bruck-Ryser-Chowla Theorem

If $n \equiv 1, 2 \pmod 4$, and the SQUAREFREE part of n is divisible by a PRIME $p \equiv 3 \pmod 4$, then no DIFFERENCE SET of ORDER n exists. Equivalently, if a PROJECTIVE PLANE of order n exists, and $n = 1$ or 2 (mod 4), then n is the sum of two SQUARES.

Dinitz and Stinson (1992) give the theorem in the following form. If a symmetric (v, k, λ)-BLOCK DESIGN exists, then

1. If v is EVEN, then $k - \lambda$ is a SQUARE NUMBER,
2. If v is ODD, then the DIOPHANTINE EQUATION

$$x^2 = (k - \lambda)y^2 + (-1)^{(v-1)/2}\lambda z^2$$

has a solution in integers, not all of which are 0.

Brun's Constant

The number obtained by adding the reciprocals of the odd TWIN PRIMES,

$$B \equiv (\tfrac{1}{3} + \tfrac{1}{5}) + (\tfrac{1}{5} + \tfrac{1}{7}) + (\tfrac{1}{11} + \tfrac{1}{13}) + (\tfrac{1}{17} + \tfrac{1}{19}) + \cdots, \quad (1)$$

By BRUN'S THEOREM, the constant converges to a definite number as $p \to \infty$. Any finite sum underestimates B. Shanks and Wrench (1974) used all the TWIN PRIMES among the first 2 million numbers. Brent (1976) calculated all TWIN PRIMES up to 100 billion and obtained (Ribenboim 1989, p. 146)

$$B \approx 1.90216054, \quad (2)$$

assuming the truth of the first HARDY-LITTLEWOOD CONJECTURE. Using TWIN PRIMES up to 10^{14}, Nicely (1996) obtained

$$B \approx 1.9021605778 \pm 2.1 \times 10^{-9} \quad (3)$$

(Cipra 1995, 1996), in the process discovering a bug in Intel's® Pentium™ microprocessor. Using TWIN PRIMES up to 2.55^{15}, Nicely subsequently obtained the result

$$B \approx 1.9021605820 \pm 2.4 \times 10^{-9}. \quad (4)$$

(Note that the value given by Le Lionnais 1983 is incorrect)

Segal (1930) proved that Brun-type sums B_d of $1/p$ over consecutive primes separated by d are finite (Halberstam and Richert 1983, p. 92). Wolf suggests that B_d is roughly equal to $4/d$ which, in the $d = 2$ case of twin primes, gives $B_2 \approx 2$ instead of 1.902.... Wolf also considers the "COUSIN PRIMES" Brun's constant B_4.

Brute Force Factorization

DIRECT SEARCH FACTORIZATION

B-Spline

A generalization of the BÉZIER CURVE. Let a vector known as the KNOT VECTOR be defined

$$\mathbf{T} = \{t_0,\ t_1,\ \ldots,\ t_m\}, \quad (1)$$

where $\mathbf{T}$ is a nondecreasing SEQUENCE with $t_i \in [0,\ 1]$, and define control points $\mathbf{P}_0, \ldots, \mathbf{P}_n$. Define the degree as

$$p \equiv m - n - 1. \quad (2)$$

The "knots" $t_{p+1}, \ldots, t_{m-p-1}$ are called INTERNAL KNOTS.

Define the basis functions as

$$N_{i,0}(t) = \begin{cases} 1 & \text{if } t_i \leq t < t_{i+1} \text{ and } t_i < t_{i+1} \\ 0 & \text{otherwise} \end{cases} \quad (3)$$

$$N_{i,\,p}(t) = \frac{t - t_i}{t_{i+p} - t_i} N_{i,\,p-1}(t) + \frac{t_{i+p+1} - t}{t_{i+p+1} - t_{i+1}} N_{i+1,\,p-1}(t). \quad (4)$$

Then the curve defined by

$$\mathbf{C}(t) = \sum_{i=0}^{n} \mathbf{P}_i N_{i,p}(t) \quad (5)$$

is a B-spline. Specific types include the nonperiodic B-spline (first $p+1$ knots equal 0 and last $p+1$ equal to 1) and uniform B-spline (INTERNAL KNOTS are equally spaced). A B-spline with no INTERNAL KNOTS is a BÉZIER CURVE.

A curve is $p-k$ times differentiable at a point where k duplicate knot values occur. The knot values determine the extent of the control of the control points.

See also BÉZIER CURVE, NURBS CURVE

B-Tree

B-trees were introduced by Bayer (1972) and McCreight. They are a special m-ary balanced tree used in databases because their structure allows records to be inserted, deleted, and retrieved with guaranteed worst-case performance. An n-node B-tree has height $\mathcal{O}(\lg 2)$, where LG is the LOGARITHM to base 2. The Apple ® Macintosh ® (Apple Computer, Cupertino, CA) HFS filing system uses B-trees to store disk directories (Benedict 1995). A B-tree satisfies the following properties:

1. The ROOT is either a LEAF (TREE) or has at least two CHILDREN.
2. Each node (except the ROOT and LEAVES) has between $\lceil m/2 \rceil$ and m CHILDREN, where $\lceil x \rceil$ is the CEILING FUNCTION.
3. Each path from the ROOT to a LEAF (TREE) has the same length.

Every 2– TREE is a B-tree of order 3. The number of B-trees of order-3 with $n = 1, 2, \ldots$ leaves are 1, 1, 1, 1, 2, 2, 3, 4, 5, 8, 14, 23, 32, 43, 63, ... (Ruskey, Sloane's A014535). The number of order-4 B-trees with $n = 1$,

2, ... leaves are 1, 1, 1, 2, 2, 4, 5, 9, 15, 28, 45, ... (Sloane's A037026).

Bubble

A bubble is a minimal-energy surface of the type that is formed by soap film. The simplest bubble is a single SPHERE, illustrated above (courtesy of J. M. Sullivan). More complicated forms occur when multiple bubbles are joined together. The simplest example is the DOUBLE BUBBLE, and beautiful configurations can form when three or more bubbles are conjoined (Sullivan).

An outstanding problem involving bubbles is the determination of the arrangements of bubbles with the smallest SURFACE AREA which enclose and separate n given volumes in space.

Buchowski Paradox

A paradox arising in the use of comparative adjectives. Suppose you have exactly two brothers, both of whom are older than you are. Then the following apparently false statement is actually true: "My younger brother is older than I am."

Buckminster Fuller Dome

GEODESIC DOME

Buffon's Needle Problem

Find the probability $P(\ell, d)$ that a needle of length ℓ will land on a line, given a floor with equally spaced PARALLEL LINES a distance d apart. The problem was first posed by the French naturalist Buffon in 1733, and reproduced with the solution by Buffon in 1777. For $\ell \leq d$,

$$P(\ell, d) = \int_0^{2\pi} \frac{\ell|\cos\theta|}{d} \frac{d\theta}{2\pi} = \frac{\ell}{2\pi d} 4\int_0^{\pi/2} \cos\theta \, d\theta$$

$$= \frac{2\ell}{\pi d}[\sin\theta]_0^{\pi/2} = \frac{2\ell}{\pi d}. \quad (1)$$

For $\ell \geq d$, the solution is slightly more complicated,

$$P(\ell, d) = \frac{1}{\pi d}\left\{d\left[\pi - 2\sin^{-1}\left(\frac{d}{\ell}\right)\right] + 2\ell\left(1 - \sqrt{1 - \frac{d^2}{\ell^2}}\right)\right\} \quad (2)$$

(Uspensky 1937, p. 252; Kunkel).

Several attempts have been made to experimentally determine π by needle-tossing. For a discussion of the relevant statistics and a critical analysis of one of the more accurate (and least believable) needle-tossings, see Badger (1994). Uspensky (1937, pp. 112–113) discusses experiments conducted with 2520, 3204, and 5000 trials. An asymptotically unbiased estimator for π from the needle-tossing experiment is

$$\hat{\pi} = \frac{2rn}{N}, \quad (3)$$

where $r = \ell/d$, n is the number of throws, and N is the number of line crossings, which has asymptotic variance

$$\text{var}(\hat{\pi}) = \frac{\pi^2}{n}(\tfrac{1}{2}\pi - 1) \approx \frac{5.63}{n} \quad (4)$$

(Mantel 1953; Solomon 1978, p. 7).

If the needle is longer than the distance between two lines, then the probability that it intersects at least one line is

$$P(\ell) = \frac{2\ell}{\pi d}(1 - \sin\phi_0) + \frac{2\phi_0}{\pi}, \quad (5)$$

where $\cos\phi_0 = d/\ell$ (Uspensky 1937, p. 258).

The problem can be extended to a "needle" in the shape of a CONVEX POLYGON with GENERALIZED DIAMETER less than d. The probability that the boundary of the polygon will intersect one of the lines is given by

$$P = \frac{p}{\pi d}, \quad (6)$$

where p is the PERIMETER of the polygon (Uspensky 1937, p. 253; Solomon 1978, p. 18). A further generalization obtained by throwing a needle on a board ruled with two sets of perpendicular lines is called the BUFFON-LAPLACE NEEDLE PROBLEM.

Buffon-Laplace Needle Problem

Find the probability $P(\ell, a, b)$ that a needle of length ℓ will land on a line, given a floor with a grid of equally spaced PARALLEL LINES distances a and b apart, with $\ell < a, b$. The position of the needle can be specified with points (x, y) and its orientation with coordinate ϕ. By symmetry, we can consider a single rectangle of the grid, so $0 < x < a$ and $0 < y < b$. In

addition, since opposite orientations are equivalent, we can take $-\pi/2 < \phi < \pi/2$.
The probability is given by

$$P(\ell;\ a, b) = 1 - \frac{\int_{-\pi/2}^{\pi/2} F(\phi)\, d\phi}{\pi ab}, \tag{1}$$

where

$$F(\phi) = ab - b\ell \cos\phi - \ell a|\sin\phi| + \tfrac{1}{2}\ell^2|\sin(2\phi)| \tag{2}$$

(Uspensky 1937, p. 256; Solomon 1978, p. 4), giving

$$P(\ell;\ a, b) = \frac{2\ell(a+b) - \ell^2}{\pi ab}. \tag{3}$$

If the plane is instead tiled with congruent triangles with sides a, b, c, and a needle with length ℓ less than the shortest altitude is thrown, the probability that the needle is contained entirely within one of the triangles is given by

$$P = 1 + \frac{(Aa^2 + Bb^2 + Cc^2)\ell^2}{2\pi K^2} - \frac{(4a + 4b + 4c - 3\ell)\ell}{2\pi K}, \tag{4}$$

where A, B, and C are the angles opposite a, b, and c, respectively, and K is the AREA of the triangle. For equilateral triangles, this simplifies to

$$P = 1 + \frac{2}{3}\left(\frac{\ell}{a}\right)^2 - \frac{\ell\sqrt{3}}{\pi a}\left(4 - \frac{\ell}{a}\right) \tag{5}$$

(Uspensky 1937, p. 258).

Bump Function

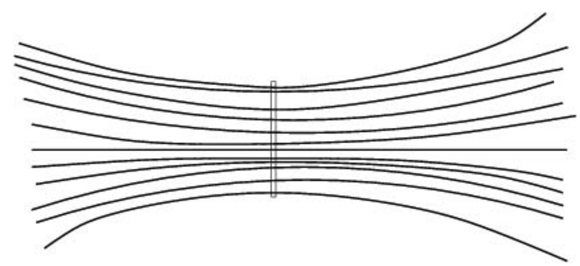
Given any OPEN SET U in $\mathbb{R}^n$ with COMPACT CLOSURE $K = \bar{U}$, there exists SMOOTH FUNCTIONS which are identically one on U and vanish arbitrarily close to U. One way to express this more precisely is that for any OPEN SET V containing K, there is a SMOOTH FUNCTION f such that

1. $f(x) = 1$ for all $x \in U$ and
2. $f(x) = 0$ for all $x \notin V$.

A function f that satisfies (1) and (2) is called a bump function. If $\int f = 1$ then by rescaling f, namely $f_k(x) = k^n f(kx)$, one gets a sequence of smooth functions which converges to the DELTA FUNCTION.

See also COMPACT SUPPORT, CONVOLUTION, DIRAC DISTRIBUTION, SMOOTH FUNCTION

Bumping Algorithm



Given a PERMUTATION $\{p_1, p_2, \ldots, p_n\}$ of $\{1, \ldots, n\}$, the bumping algorithm constructs a standard YOUNG TABLEAU by inserting the p_i one by one into an already constructed YOUNG TABLEAU. To apply the bumping algorithm, start with $\{\{p_1\}\}$, which is a YOUNG TABLEAU. If p_1 through p_k have already been inserted, then in order to insert p_{k+1}, start with the first line of the already constructed YOUNG TABLEAU and search for the first element of this line which is greater than p_{k+1}. If there is no such element, append p_{k+1} to the first line and stop. If there is such an element (say, p_p), exchange p_p for p_{k+1}, search the second line using p_p, and so on.

See also TABLEAU CLASS, YOUNG TABLEAU

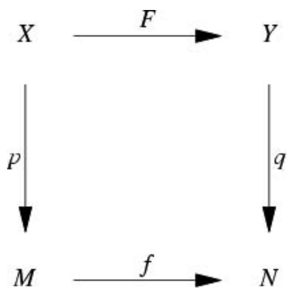
Bundle

The term "bundle" is an abbreviated form of the full term FIBER BUNDLE. Depending on context, it may mean one of the special cases of FIBER BUNDLES, such as a VECTOR BUNDLE or a PRINCIPAL BUNDLE. Bundles are so named because they contain a collection of objects which, like a bundle of hay, are held together in a special way. All of the fibers line up–or at least they line up to nearby fibers.
LOCALLY, a bundle looks like a PRODUCT MANIFOLD in a TRIVIALIZATION. The graph of a function f sits inside the product as $(x, f(x))$. The SECTIONS of a bundle generalize functions in this way. It is necessary to use bundles when the range of a function only makes sense locally, as in the case of a VECTOR FIELD on the SPHERE.

Bundles are a special kind of SHEAF.



See also FIBER BUNDLE, JET BUNDLE, LINE BUNDLE, PRINCIPAL BUNDLE, SHEAF, TANGENT BUNDLE, VECTOR BUNDLE

Bundle Map

A bundle map is a map between bundles along with a compatible map between the BASE MANIFOLDS. Suppose $p : X \to M$ and $q : Y \to N$ are two BUNDLES, then

$$F: X \to Y$$

is a bundle map if there is a map $f: M \to N$ such that $q(F(x)) = f(p(x))$ for all $x \in X$. In particular, the FIBER of X over a point $m \in M$, gets mapped to the fiber of Y over $f(m) \in N$.

In the language of CATEGORY THEORY, the above diagram COMMUTES. To be more precise, the induced map between fibers has to be a map in the category of the fiber. For instance, in a bundle map between VECTOR BUNDLES the fiber over $m \in M$ is mapped to the fiber over $f(m) \in M$ by a LINEAR TRANSFORMATION.

For example, when $f: M \to N$ is a SMOOTH MAP between SMOOTH MANIFOLDS then $df: TM \to TN$ is the differential, which is a bundle map between the tangent bundles. Over any point in $m \in M$, the tangent vectors at m get mapped to tangent vectors at $f(m) \in N$ by the JACOBIAN.

Buniakowsky Inequality

SCHWARZ'S INEQUALITY

Burali-Forti Paradox

In the theory of transfinite ORDINAL NUMBERS,

1. Every WELL ORDERED SET has a unique ORDINAL NUMBER,
2. Every segment of ordinals (i.e., any set of ordinals arranged in natural order which contains all the predecessors of each of its elements) has an ORDINAL NUMBER which is greater than any ordinal in the segment, and
3. The set B of all ordinals in natural order is well ordered.

Then by statements (3) and (1), B has an ordinal β. Since β is in B, it follows that $\beta < \beta$ by (2), which is a contradiction.

Bürmann's Theorem

Bürmann's theorem deals with the expansion of functions in powers of another function. Let $\phi(z)$ be a function of z which is analytic in a closed region S, of which a is an interior point, and let $\phi(a) = b$. Suppose also that $\phi'(a) \neq 0$. Then TAYLOR'S THEOREM furnishes the expansion

$$\phi(z) - b = \phi'(a)(z-a) + \frac{\phi''(a)}{2!}(z-a)^2 + \ldots, \tag{1}$$

and if it is legitimate to revert this series, we obtain

$$z - a = \frac{\phi(z) - b}{\phi'(a)} - \frac{1}{2}\frac{\phi''(a)}{[\phi'(a)]^3}[\phi(z) - b]^2 + \ldots, \tag{2}$$

which expresses z as an ANALYTIC FUNCTION of the variable $\phi(z) - b$ for sufficiently small values of $|z-a|$. If then $f(z)$ is analytic near $z = a$, it follows that $f(z)$ is an ANALYTIC FUNCTION of $\phi(z) - b$ when $|z-a|$ is sufficiently small, and so there will be an expansion in the form

$$f(z) = f(a) + a_1[\phi(z) - b] + \frac{a_2}{2!}[\phi(z) - b]^2 + \frac{a_3}{3!}[\phi(z) - b]^3 + \ldots \tag{3}$$

The actual coefficients in the expansion are given by the following theorem, which is generally known as Bürmann's theorem. Let $\psi(z)$ be a function of z defined by the equation

$$\psi(z) = \frac{z-a}{\phi(z) - b}. \tag{4}$$

Then an ANALYTIC FUNCTION $f(z)$ can, in a certain domain of values of z, be expanded in the form

$$f(z) = f(a) + \sum_{m=1}^{n-1} \frac{[\phi(z) - b]^m}{m!} \frac{d^{m-1}}{da^{m-1}}\{f'(a)[\psi(a)]^m\} + R_n, \tag{5}$$

where the remainder term is

$$R_n = \frac{1}{2\pi i}\int_a^x \int_\gamma \left[\frac{\phi(z) - b}{\phi(t) - b}\right]^{n-1} \frac{f'(t)\phi'(z)\,dt\,dz}{\phi(t) - \phi(z)}, \tag{6}$$

and γ is a CONTOUR in the t-plane enclosing the points a and z such that if ζ is any point inside γ, the equation $\phi(t) = \phi(\zeta)$ has no roots on or inside the CONTOUR except a simple root $t = \zeta$.

TEIXEIRA'S THEOREM is extended form of Bürmann's theorem. The LAGRANGE EXPANSION gives another such extension.

Burnside Problem

A problem originating with W. Burnside (1902), who wrote, "A still undecided point in the theory of discontinuous groups is whether the ORDER of a GROUP may be not finite, while the order of every operation it contains is finite." This question would now be phrased as "Can a finitely generated group be infinite while every element in the group has finite order?" (Vaughan-Lee 1990). This question was answered by Golod (1964) when he constructed finitely generated infinite p-GROUP. These GROUPS, however, do not have a finite exponent.

Let F_r be the FREE GROUP of RANK r and let N be the NORMAL SUBGROUP generated by the set of nth POWERS $\{g^n | g \in F_r\}$. Then N is a normal subgroup of F_r. We define $B(r, n) = F_r/N$ to be the QUOTIENT GROUP. We call $B(r, n)$ the r-generator Burnside group of exponent n. It is the largest r-generator group of exponent n, in the sense that every other

such group is a HOMOMORPHIC image of $B(r, n)$. The Burnside problem is usually stated as: "For which values of r and n is $B(r, n)$ a FINITE GROUP?"

An answer is known for the following values. For $r=1$, $B(1, n)$ is a CYCLIC GROUP of ORDER n. For $n=2$, $B(r, 2)$ is an elementary ABELIAN 2-group of ORDER 2^r. For $n=3$, $B(r, 3)$ was proved to be finite by Burnside. The ORDER of the $B(r, 3)$ groups was established by Levi and van der Waerden (1933), namely 3^a where

$$a \equiv r + \binom{r}{2} + \binom{r}{3}, \tag{1}$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT. For $n=4$, $B(r, 4)$ was proved to be finite by Sanov (1940). Groups of exponent four turn out to be the most complicated for which a POSITIVE solution is known. The precise nilpotency class and derived length are known, as are bounds for the ORDER. For example,

$$|B(2, 4)| = 2^{12} \tag{2}$$

$$|B(3, 4)| = 2^{69} \tag{3}$$

$$|B(4, 4)| = 2^{422} \tag{4}$$

$$|B(5, 4)| = 2^{2728}, \tag{5}$$

while for larger values of r the exact value is not yet known. For $n=6$, $B(r, 6)$ was proved to be finite by Hall (1958) with ORDER $2^a 3^b$, where

$$a \equiv 1 + (r-1)3^c \tag{6}$$

$$b \equiv 1 + (r-1)2^r \tag{7}$$

$$c \equiv r + \binom{r}{2} + \binom{r}{3}. \tag{8}$$

No other Burnside groups are known to be finite. On the other hand, for $r>2$ and $n \geq 665$, with n ODD, $B(r, n)$ is infinite (Novikov and Adjan 1968). There is a similar fact for $r>2$ and n a large POWER of 2.

E. Zelmanov was awarded a FIELDS MEDAL in 1994 for his solution of the "restricted" Burnside problem.

Burnside's Conjecture

This entry contributed by NICOLAS BRAY

In Note M, Burnside (1955) states, "The contrast that these results shew between groups of odd and of even order suggests inevitably that simple groups of odd order do not exist." Of course, SIMPLE GROUPS of prime order do exist, namely the groups $\mathbb{Z}_p$ for any prime p. Therefore, Burnside conjectured that every FINITE SIMPLE GROUP of non-prime order must have even order. The conjecture was proven true by Feit and Thompson (1963).

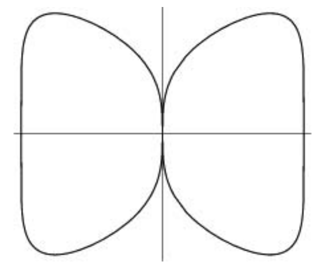
Butterfly Catastrophe

A CATASTROPHE which can occur for four control factors and one behavior axis. The butterfly catastrophe is the universal unfolding of the singularity $f(x) = x^6$ of codimension 4, i.e., with four unfolding parameters. It has the form $F(x,\ u,\ v,\ w,\ t) = x^6 + ux^4 + vx^3 + wx^2 + tx$.

The equations

$$x = c(8at^3 + 24t^5)$$

$$y = c(-6at^2 - 15t^4)$$



display such a catastrophe (von Seggern 1993).

Butterfly Theorem

Given a CHORD PQ of a CIRCLE, draw any other two CHORDS AB and CD passing through its MIDPOINT. Call the points where AD and BC meet PQ X and Y. Then M is also the MIDPOINT of XY. There are a number of proofs of this theorem, including those by W. G. Horner, Johnson (1929, p. 78), and Coxeter (1987, pp. 78 and 144). The latter concise proof employs PROJECTIVE GEOMETRY.

The following proof is given by Coxeter and Greitzer (1967, p. 46). In the figure at right, drop perpendiculars x_1 and y_1 from X and Y to AB, and x_2 and y_2 from X and Y to CD. Write $a = PM = MQ$, $x = XM$, and $y = MY$, and then note that by SIMILAR TRIANGLES

$$\frac{x}{y} = \frac{x_1}{y_1} = \frac{x_2}{y_2} \tag{1}$$

$$\frac{x_1}{y_2} = \frac{AX}{CY} \tag{2}$$

$$\frac{x_2}{y_1} = \frac{XD}{YB}, \tag{3}$$

so

$$\frac{x^2}{y^2} = \frac{x_1}{y_1}\frac{x_2}{y_2} = \frac{x_1}{y_2}\frac{x_2}{y_1} = \frac{AX \cdot XD}{CY \cdot YB} = \frac{PX \cdot XQ}{PY \cdot YQ}$$

$$= \frac{(a-x)(a+x)}{(a+y)(a-y)} = \frac{a^2-x^2}{a^2-y^2} = \frac{a^2}{a^2} = 1, \tag{4}$$

so $x = y$. Q.E.D.

Cage Graph

A 3-regular g-cage for $g \geq 3$ is a CUBIC GRAPH of GIRTH g with the minimum possible number of points. More generally, an (v, g)-cage graph is a smallest v-regular graph with GIRTH g. Cubic cages were first discussed by Tutte (1947), but the intensive study of cage graphs did not begin until publication of an article by Erdos and Sachs (1963). There exists a $(3, g)$-cage for all $g \geq 3$, and the $(3, g)$-cages are unique for $g = 3$ to 8. The number of nonisomorphic $(3, g)$ cages for $g = 1, 2, \ldots$ are given by 0, 0, 1, 1, 1, 1, 1, 1, 18, 3, ... (Sloane's A052453; Gould 1988, Royle). The number of vertices in the $(3, g)$ cages for $g = 3, 4, \ldots$ are 4, 6, 10, 14, 22, 30, 46, 62, 94, ... (Sloane's A052454). A selection of known $(3, g)$-cages are illustrated above. There are a number of special cases (Wong 1982). The $(2, g)$-cage is the CYCLE GRAPH C_g, the $(v, 2)$-cage is the MULTIGRAPH of v edges on two vertices, the $(v, 3)$-cage is the COMPLETE GRAPH K_{v+1}, and the $(v, 4)$-cage is the BIPARTITE GRAPH $K_{v, v}$.

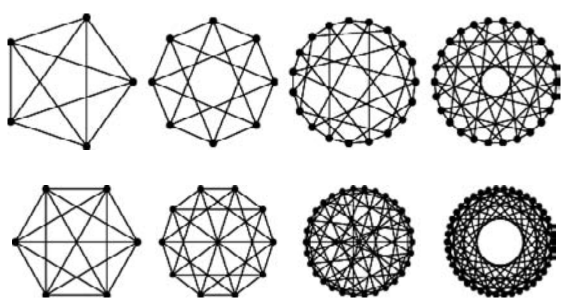
Computing the number of vertices in a (v, g)-cage is very difficult for $g \geq 5$ and $n \geq 3$ (Wong 1982). The following table summarizes known cages. A lower bound for the number of vertices $f(v, g)$ in a (v, g)-cage is given by

$$f_l(v, g) = \begin{cases} \dfrac{v(v-1)^r - 2}{v-2} & \text{for } g = 2r+1 \\ \dfrac{2(v-1)^r - 2}{v-2} & \text{for } g = 2r \end{cases}$$

(Tutte 1967, p. 70; Bollobás 1978, p. 105; Wong 1982). Sauer (1967ab) has obtained the best known upper bounds

$$f_u(3, g) = \begin{cases} \frac{4}{3} + \frac{29}{12} 2^{g-2} & \text{for } g \text{ odd} \\ \frac{2}{3} + \frac{29}{12} 2^{g-2} & \text{for } g \text{ even} \end{cases} \tag{1}$$

$$f_u(n, g) = \begin{cases} 2(n-1)^{g-2} & \text{for } g \text{ odd} \\ 2(n-1)^{g-3} & \text{for } g \text{ even,} \end{cases} \tag{2}$$



with $v \geq 4$ (Wong 1982).

In the table, K_n denotes a COMPLETE GRAPH, and $K_{m, n}$ a complete bipartite graph.

g	$(3, g)$	$(4, g)$	$(5, g)$	$(6, g)$	$(7, g)$-cage
3	K_4	K_5	K_6	K_7	K_8
4	$K_{3, 3}$	$K_{4, 4}$	$K_{5, 5}$	$K_{6, 6}$	$K_{7, 7}$
5	PETERSEN GRAPH	ROBERTSON GRAPH	ROBERTSON-WEGNER GRAPH		HOFFMAN-SINGLETON GRAPH
6	HEAWOOD GRAPH				
7	MCGEE GRAPH				
8	LEVI GRAPH				

g	$f(3, g)$	$f(4, g)$	$f(5, g)$	$f(6, g)$	$f(7, g)$
3	4	5	6	7	8
4	6	8	10	12	14
5	10	19	30	40	50
6	14	26	42	62	90
7	24				
8	30				
9	[54, 58]				
10	70				
11	< 112				

The first (3, 9)-cage was found by Biggs and Hoare (1980), and Brinkmann *et al.* (1995) completed an exhaustive search yielding all 18 (3, 9)-cages (Royle). The three (3, 10)-cages were found by O'Keefe and Wong (1980). Computations by McKay and W. Myrvold have demonstrated that a (3, 11)-cage must have 112 vertices (Royle). The single known example was found by Balaban (1973).

The known (4, g)- and (5, g)-cages are shown above (Wong 1982).

Cake Cutting

It is always possible to "fairly" divide a cake among n people using only vertical cuts. Furthermore, it is possible to cut and divide a cake such that each person believes that *everyone* has received $1/n$ of the cake according to his own measure (Steinhaus 1983, pp. 65–71). Finally, if there is some piece on which two people disagree, then there is a way of partitioning and dividing a cake such that each participant believes that he has obtained more than $1/n$ of the cake according to his own measure.

There are also similar methods of dividing collections of individually indivisible objects among two or more people when cash payments are used to even up the final division (Steinhaus 1983, pp. 67–68).

Ignoring the height of the cake, the cake-cutting problem is really a question of fairly dividing a CIRCLE into n equal AREA pieces using cuts in its plane. One method of proving fair cake cutting to always be possible relies on the FROBENIUS-KÖNIG THEOREM.

Calabi-Yau Manifold

CALABI-YAU SPACE

Calabi-Yau Space

Calabi-Yau spaces are important in string theory, where one model posits the geometry of the universe to consist of a ten-dimensional space OF THE FORM $M \times V$, where M is a four dimensional manifold (space-time) and V is a six dimensional COMPACT Calabi-Yau space. They are related to KUMMER SURFACES. Although the main application of Calabi-Yau spaces is in theoretical physics, they are also interesting from a purely mathematical standpoint. Consequently, they go by slightly different names, depending mostly on context, such as Calabi-Yau manifolds or Calabi-Yau varieties.

Although the definition can be generalized to any dimension, they are usually considered to have three complex dimensions. Since their COMPLEX STRUCTURE may vary, it is convenient to think of them as having six real dimensions and a fixed SMOOTH STRUCTURE.

A Calabi-Yau space is characterized by the existence of a NONVANISHING HARMONIC SPINOR ϕ. This condition implies that its CANONICAL BUNDLE is TRIVIAL.

Consider the local situation using coordinates. In $\mathbb{R}^6$, pick coordinates x_1, x_2, x_3 and y_1, y_2, y_3 so that

$$z_j = x_j + iy_j \tag{1}$$

gives it the structure of $\mathbb{C}^3$. Then

$$\phi_z = dz_1 \wedge dz_2 \wedge dz_3 \tag{2}$$

is a local section of the canonical bundle. A unitary change of coordinates $w = Az$, where A is a UNITARY MATRIX, transforms ϕ by det A, i.e.

$$\phi_w = \det A \phi_z. \tag{3}$$

If the linear transformation A has DETERMINANT 1, that is, it is a special unitary transformation, then ϕ is consistently defined as ϕ_z or as ϕ_w.

On a Calabi-Yau manifold V, such a ϕ can be defined globally, and the LIE GROUP $SU(3)$ is very important in the theory. In fact, one of the many equivalent definitions, coming from RIEMANNIAN GEOMETRY, says that a Calabi-Yau manifold is a $2n$-dimensional manifold whose HOLONOMY GROUP reduces to $SU(n)$. Another is that it is a CALIBRATED MANIFOLD with a CALIBRATION FORM ψ, which is algebraically the same as the REAL PART of

$$dz_1 \wedge \ldots \wedge dz_n. \tag{4}$$

Often, the extra assumptions that V is SIMPLY CONNECTED and/or COMPACT are made.

Whatever definition is used, Calabi-Yau manifolds, as well as their MODULI SPACES, have interesting properties. One is the symmetries in the numbers forming the HODGE DIAMOND of a compact Calabi-Yau manifold. It is surprising that these symmetries, called MIRROR SYMMETRY, can be realized by another Calabi-Yau manifold, the so-called mirror of the original Calabi-Yau manifold. The two manifolds together form a MIRROR PAIR. Some of the symmetries of the geometry of mirror pairs have been the object of recent research.

Calabi-Yau Variety

CALABI-YAU SPACE

Calculus

In general, "a" calculus is an abstract theory developed in a purely formal way.

"The" calculus, more properly called ANALYSIS (or REAL ANALYSIS or, in older literature, INFINITESIMAL ANALYSIS) is the branch of mathematics studying the rate of change of quantities (which can be interpreted as SLOPES of curves) and the length, AREA, and VOLUME of objects. The calculus is sometimes divided into DIFFERENTIAL and INTEGRAL CALCULUS, concerned with DERIVATIVES

$$\frac{d}{dx} f(x)$$

and INTEGRALS

$$\int f(x)\, dx,$$

respectively.

While ideas related to calculus had been known for some time (Archimedes' EXHAUSTION METHOD was a form of calculus), it was not until the independent work of Newton and Leibniz that the modern elegant tools and ideas of calculus were developed. Even so, many years elapsed until the subject was put on a mathematically rigorous footing by mathematicians such as Weierstrass.

Calculus of Variations

A branch of mathematics which is a sort of generalization of CALCULUS. Calculus of variations seeks to find the path, curve, surface, etc., for which a given FUNCTION has a STATIONARY VALUE (which, in physical problems, is usually a MINIMUM or MAXIMUM). Mathematically, this involves finding STATIONARY VALUES of integrals OF THE FORM

$$i = \int_b^a f(y, \dot{y}, x)\, dx. \qquad (1)$$

i has an extremum only if the EULER-LAGRANGE DIFFERENTIAL EQUATION is satisfied, i.e., if

$$\frac{\partial f}{\partial y} - \frac{d}{dx}\left(\frac{\partial f}{\partial \dot{y}}\right) = 0. \qquad (2)$$

the FUNDAMENTAL LEMMA OF CALCULUS OF VARIATIONS states that, if

$$\int_a^b M(x)h(x)\, dx = 0 \qquad (3)$$

for all $h(x)$ with CONTINUOUS second PARTIAL DERIVATIVES, then

$$M(x) = 0 \qquad (4)$$

on (a, b).

A generalization of calculus of variations known as MORSE THEORY (and sometimes called "calculus of variations in the large" uses nonlinear techniques to address variational problems.

Caliban Puzzle

A puzzle in LOGIC in which one or more facts must be inferred from a set of given facts.

Calibration Form

A calibration form on a RIEMANNIAN MANIFOLD M is a DIFFERENTIAL K-FORM ϕ such that

1. ϕ is a CLOSED FORM.
2. The COMASS of ϕ,

$$\sup_{v \in \wedge pTM,\ |v|=1} |\phi(v)| \qquad (1)$$

defined as the largest value of ϕ on a p vector of p-volume one, equals 1.

A p-dimensional submanifold is calibrated when ϕ restricts to give the VOLUME FORM.

It is not hard to see that a calibrated submanifold N minimizes its volume among objects in its HOMOLOGY CLASS. By STOKES' THEOREM, if N' represents the same homology class, then

$$\int_N \phi = \int_{N'} \phi. \qquad (2)$$

Since

$$\text{vol}(N) = \int_N \phi \qquad (3)$$

and

$$\text{vol}(N') \geq \int_{N'} \phi, \qquad (4)$$

it follows that the volume of N is less than or equal to the volume of N'.

A simple example is dx on the plane, for which the lines $y = c$ are calibrated submanifolds. In fact, in this example, the calibrated submanifolds give a FOLIATION. On a KÄHLER MANIFOLD, the KÄHLER FORM ω is a calibration form, which is INDECOMPOSABLE. For example, on

$$\mathbb{C}^2 = \{(x_1 + y_1 i,\ x_2 + y_2 i)\}, \qquad (5)$$

the Kähler form is

$$dx_1 \wedge dy_1 + dx_2 \wedge dy_2. \qquad (6)$$

On a KÄHLER MANIFOLD, the calibrated submanifolds are precisely the complex submanifolds. Consequently, the complex submanifolds are locally volume minimizing.

Campbell's Theorem

Any n-dimensional Riemannian manifold can be locally embedded into an $(n+1)$-dimensional manifold with Ricci curvature $R_{ab}=0$. A similar version of the theorem for a pseudo-Riemannian manifold states that any n-dimensional pseudo-Riemannian manifold can be locally and isometrically embedded in an $n(n+1)/2$-dimensional pseudo-Euclidean space.

Cannonball Problem

Find a way to stack a square of cannonballs laid out on the ground into a square pyramid (i.e., find a square number which is also square pyramidal). This corresponds to solving the Diophantine equation

$$\sum_{i=1}^{k} i^2 = \tfrac{1}{6} k(1+k)(1+2k) = N^2$$

for some pyramid height k. The only solution is $k=24$, $N=70$, corresponding to 4900 cannonballs (Ball and Coxeter 1987, Dickson 1952), as conjectured by Lucas (1875, 1876) and proved by Watson (1918).

Canonical

The word canonical is used to indicate a particular choice from of a number of possible conventions. This

convention allows a mathematical object or class of objects to be uniquely identified or standardized. For example, the RIGHT-HAND RULE for the CROSS PRODUCT is a convention, which corresponds to the canonical ORIENTATION in $\mathbb{R}^3$.

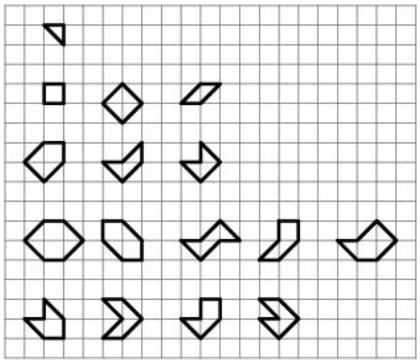
Canonical Bundle

The canonical bundle is a HOLOMORPHIC LINE BUNDLE on a COMPLEX MANIFOLD which is determined by its COMPLEX STRUCTURE. On a coordinate chart $(z_1, \ldots z_n)$, it is spanned by the nonvanishing section $dz_1 \wedge \ldots \wedge dz_n$. The TRANSITION FUNCTION between COORDINATE CHARTS is given by the determinant of the JACOBIAN of the coordinate change.

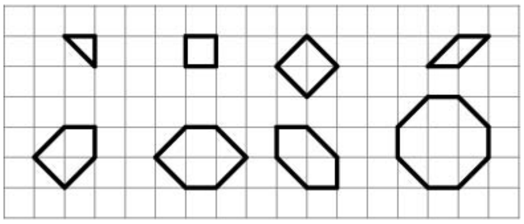
The canonical bundle is defined in a similar way to the HOLOMORPHIC TANGENT BUNDLE. In fact, it is the nth EXTERIOR POWER of the DUAL BUNDLE to the HOLOMORPHIC TANGENT BUNDLE.

Canonical Form



A clear-cut way of describing every object in a class in a ONE-TO-ONE manner.

See also NORMAL FORM, ONE-TO-ONE



References

Canonical Polygon

A closed polygon whose vertices lie on a POINT LATTICE and whose edges consist of vertical and horizontal steps of unit length or diagonal steps (at angles which are multiples of 45° with respect to the lattice axes) of length $\sqrt{2}$. In addition, no two steps may be taken in the same direction, no edge intersections are allowed, and no point may be a vertex of two edges. The numbers of distinct canonical polygons of $n = 1, 2, \ldots$ sides are 0, 0, 1, 3, 3, 9, 13, 48, 125, ... (Sloane's A052436).

There are exactly eight distinct convex canonical polygons, illustrated above.
The concept can also be generalized to diagonals rotated with respect to the lattice axes.

See also GOLYGON, LATTICE POLYGON

Canonical Polyhedron

A POLYHEDRON is said to be canonical if all its EDGES touch a SPHERE and the center of gravity of their contact points is the center of that SPHERE. Each combinatorial type of (GENUS zero) polyhedron contains just one canonical version. The ARCHIMEDEAN SOLIDS and their DUALS are all canonical.

SYMPLECTIC DIFFEOMORPHISM

Cantor Comb

CANTOR SET

Cantor Diagonal Argument

CANTOR DIAGONAL METHOD

Cantor Diagonal Method

A clever technique used by Georg Cantor to show that the INTEGERS and REALS cannot be put into a ONE-TO-ONE correspondence (i.e., the UNCOUNTABLY INFINITE set of REAL NUMBERS is "larger" than the COUNTABLY INFINITE set of INTEGERS).

It proceeds by first considering a countably infinite list of elements from a set S, each of which is an infinite set (in the case of the REALS, the decimal expansion of each REAL). A new member S' of S is then created by arranging its nth term to differ from the nth term of the nth member of S. This shows that S is not COUNTABLE, since any attempt to put it in one-to-one correspondence with the integers will fail to include some elements of S. The argument is rather subtle, and requires some care to describe clearly.

See also CARDINALITY, CONTINUUM HYPOTHESIS, COUNTABLE SET, COUNTABLY INFINITE

Cantor Diagonal Slash

CANTOR DIAGONAL METHOD

Cantor Dust

A FRACTAL which can be constructed using STRING REWRITING by creating a matrix three times the size of the current matrix using the rules

line 1 : "*" → "* *", " " → "   "

line 2 : "*" → "   ", " " → "   "

line 3 : "*" → "* *", " " → "   "

Let N_n be the number of black boxes, L_n the length of a side of a box, and A_n the fractional AREA of black boxes after the nth iteration.

$$N_n = 4^n \quad (1)$$

$$L_n = (\tfrac{1}{3})^n = 3^{-n} \quad (2)$$

$$A_n = L_n^2 N_n = (\tfrac{4}{9})^n. \quad (3)$$

The CAPACITY DIMENSION is therefore

$$d_{\text{cap}} = -\lim_{n\to\infty} \frac{\ln N_n}{\ln L_n} = -\lim_{n\to\infty} \frac{\ln(4^n)}{\ln(3^{-n})} = \frac{2\ln 2}{\ln 3} \approx 1.26186. \quad (4)$$

See also BOX FRACTAL, SIERPINSKI CARPET, SIERPINSKI SIEVE

Weisstein, E. W. "Fractals." MATHEMATICA NOTEBOOK FRACTAL.M.

Cantor Function

The function whose values are

$$\frac{1}{2}\left(\frac{c_1}{2} + \ldots + \frac{c_{m-1}}{2_{m-1}} + \frac{2}{2^m}\right)$$

for any number between

$$a \equiv \frac{c_1}{3} + \ldots + \frac{c_{m-1}}{3^{m-1}} + \frac{1}{3^m}$$

and

$$b \equiv \frac{c_1}{3} + \ldots + \frac{c_{m-1}}{3^{m-1}} + \frac{2}{3^m}.$$

Chalice (1991) shows that any real-valued function $F(x)$ on [0, 1] which is MONOTONE INCREASING and satisfies

1. $F(0) = 0$,
2. $F(x/3) = F(x)/2$,
3. $F(1-x) = 1 - F(x)$

is the Cantor function.

The DEVIL'S STAIRCASE is sometimes also called the Cantor function (Devaney 1987, p. 110).

See also CANTOR SET, DEVIL'S STAIRCASE

References

Chalice, D. R. "A Characterization of the Cantor Function." *Amer. Math. Monthly* **98**, 255–258, 1991.

Devaney, R. L. *An Introduction to Chaotic Dynamical Systems.* Redwood City, CA: Addison-Wesley, 1987.

Wagon, S. "The Cantor Function" and "Complex Cantor Sets." §4.2 and 5.1 in *Mathematica in Action.* New York: W. H. Freeman, pp. 102–108 and 143–149, 1991.

Cantor Set

The Cantor set (T_∞) is given by taking the interval [0, 1] (set T_0), removing the middle third (T_1), removing the middle third of each of the two remaining pieces (T_2), and continuing this procedure ad infinitum. It is therefore the set of points in the INTERVAL [0, 1] whose ternary expansions do not contain 1, illustrated above.

This produces the SET of REAL NUMBERS $\{x\}$ such that

$$x = \frac{c_1}{3} + \ldots + \frac{c_n}{3^n} + \ldots, \tag{1}$$

where c_n may equal 0 or 2 for each n. This is an infinite, PERFECT SET. The total length of the LINE SEGMENTS in the nth iteration is

$$\ell_n = \left(\frac{2}{3}\right)^n, \tag{2}$$

and the number of LINE SEGMENTS is $N_n = 2^n$, so the length of each element is

$$\epsilon_n \equiv \frac{\ell}{N} = \left(\frac{1}{3}\right)^n \tag{3}$$

and the CAPACITY DIMENSION is

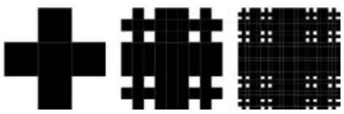
$$d_{\text{cap}} \equiv -\lim_{\epsilon \to 0+} \frac{\ln N}{\ln \epsilon} = -\lim_{n\to\infty} \frac{n \ln 2}{-n \ln 3} = \frac{\ln 2}{\ln 3} = 0.630929\ldots. \tag{4}$$

The Cantor set is nowhere DENSE, so it has LEBESGUE MEASURE 0.

A general Cantor set is a CLOSED SET consisting entirely of BOUNDARY POINTS. Such sets are UNCOUNTABLE and may have 0 or POSITIVE LEBESGUE MEASURE. The Cantor set is the only totally disconnected, perfect, COMPACT METRIC SPACE up to a HOMEOMORPHISM (Willard 1970).

See also ALEXANDER'S HORNED SPHERE, ANTOINE'S NECKLACE, CANTOR FUNCTION, CLOSED SET, SCRAWNY CANTOR SET

References



Boas, R. P. Jr. *A Primer of Real Functions.* Washington, DC: Amer. Math. Soc., 1996.

Harris, J. W. and Stocker, H. "Cantor Set." §4.11.4 in *Handbook of Mathematics and Computational Science.* New York: Springer-Verlag, p. 114, 1998.

Willard, S. §30.4 in *General Topology.* Reading, MA: Addison-Wesley, 1970.

Cantor Square Fractal

A FRACTAL which can be constructed using STRING REWRITING by creating a matrix three times the size of the current matrix using the rules

line 1: "*" → "***", " " → "   "

line 2: "*" → "* *", " " → "   "

line 3: "*" → "***", " " → "   "

The first three steps are illustrated above.

The size of the unit element after the nth iteration is

$$L_n = \left(\frac{1}{3}\right)^n$$

and the number of elements is given by the RECURRENCE RELATION

$$N_n = 4N_{n-1} + 5(9^n)$$

where $N_1 \equiv 5$, and the first few numbers of elements are 5, 65, 665, 6305, ... Expanding out gives

$$N_n = 5 \sum_{k=0}^{n} 4^{n-k} 9^{k-1} = 9^n - 4^n.$$

The CAPACITY DIMENSION is therefore

$$D = -\lim_{n\to\infty} \frac{\ln N_n}{\ln L_n} = -\lim_{n\to\infty} \frac{\ln(9^n - 4^n)}{\ln(3^{-n})} = -\lim_{n\to\infty} \frac{\ln(9^n)}{\ln(3^{-n})} = \frac{\ln 9}{\ln 3} = \frac{2 \ln 3}{\ln 3} = 2.$$

Since the DIMENSION of the filled part is 2 (i.e., the SQUARE is completely filled), Cantor's square fractal is not a true FRACTAL.

See also BOX FRACTAL, CANTOR DUST

Cantor's Intersection Theorem

A theorem about (or providing an equivalent definition of)) COMPACT SETS, originally due to Georg Cantor. Given a decreasing sequence of bounded nonempty CLOSED SETS

$$C_1 \supset C_2 \supset C_3 \supset \ldots$$

in the real numbers, then Cantor's intersection theorem states that there must exist a point p in their intersection, $p \in C_n$ for all n. For example, $0 \in \cap [0, 1/n]$. It is also true in higher DIMENSIONS of EUCLIDEAN SPACE.

Note that the hypotheses stated above are crucial. The infinite intersection of open intervals may be empty, for instance $\cap (0, 1/n)$. Also, the infinite intersection of unbounded closed sets may be EMPTY, e.g., $\cap [n, \infty]$.

Cantor's intersection theorem is closely related to the HEINE-BOREL THEOREM and BOLZANO-WEIERSTRASS THEOREM, each of which can be easily derived from either of the other two. It can be used to show that the CANTOR SET is nonempty.

See also BOLZANO-WEIERSTRASS THEOREM, BOUNDED SET, CANTOR SET, CLOSED SET, COMPACT SET, HEINE-BOREL THEOREM, INTERSECTION, REAL NUMBER, TOPOLOGICAL SPACE

Cantor's Paradox

The SET of all SETS is its own POWER SET. Therefore, the CARDINALITY of the SET of all SETS must be bigger than itself.

See also CANTOR'S THEOREM, POWER SET

References

Curry, H. B. *Foundations of Mathematical Logic.* New York: Dover, p. 5, 1977.

Capacity

TRANSFINITE DIAMETER

Capacity Dimension

A DIMENSION also called the FRACTAL DIMENSION, HAUSDORFF DIMENSION, and HAUSDORFF-BESICOVITCH DIMENSION in which nonintegral values are permitted. Objects whose capacity dimension is different from their TOPOLOGICAL DIMENSION are called FRACTALS. The capacity dimension of a compact METRIC SPACE X is a REAL NUMBER d_{capicity} such that

if $n(\epsilon)$ denotes the minimum number of open sets of diameter less than or equal to ϵ, then $n(\epsilon)$ is proportional to ϵ^{-D} as $\epsilon \to 0$. Explicitly,

$$d_{\text{capacity}} \equiv -\lim_{\epsilon \to 0^+} \frac{\ln N}{\ln \epsilon}$$

(if the limit exists), where N is the number of elements forming a finite COVER of the relevant METRIC SPACE and ϵ is a bound on the diameter of the sets involved (informally, ϵ is the size of each element used to cover the set, which is taken to approach 0). If each element of a FRACTAL is equally likely to be visited, then $d_{\text{capacity}} = d_{\text{information}}$, where $d_{\text{information}}$ is the INFORMATION DIMENSION. The capacity dimension satisfies

$$d_{\text{correlation}} \leq d_{\text{information}} \leq d_{\text{capacity}}$$

where $d_{\text{correlation}}$ is the CORRELATION DIMENSION, and is conjectured to be equal to the LYAPUNOV DIMENSION.

Cap-Cyclide Coordinates

A coordinate system obtained by INVERSION of the BICYCLIDE COORDINATES. They are given by the transformation equations

$$x = \frac{\Lambda}{a\Upsilon} \operatorname{sn} \mu \operatorname{dn} \nu \cos \psi \tag{1}$$

$$y = \frac{\Lambda}{a\Upsilon} \operatorname{sn} \mu \operatorname{dn} \nu \sin \psi \tag{2}$$

$$z = \frac{\sqrt{k} P i}{2a\Upsilon}, \tag{3}$$

where

$$\Lambda = 1 - \operatorname{dn}^2 \mu \operatorname{sn}^2 \nu \tag{4}$$

$$\Upsilon = \operatorname{sn}^2 \mu \operatorname{dn}^2 \nu + \left[\frac{\Lambda}{\sqrt{k}} + \operatorname{cn} \mu \operatorname{dn} \mu \operatorname{sn} \nu \operatorname{cn} \nu\right]^2 \tag{5}$$

$$\Pi = \frac{\Lambda^2}{k} - (\operatorname{sn}^2 \mu \operatorname{dn}^2 \nu + \operatorname{cn}^2 \mu \operatorname{dn}^2 \mu \operatorname{sn}^2 \nu \operatorname{cn}^2 \nu), \tag{6}$$

and $\operatorname{cn} x$, $\operatorname{dn} x$, and $\operatorname{sn} x$ are JACOBI ELLIPTIC FUNCTIONS. Surfaces of constant μ are ring cyclides with complicated equations (Moon and Spencer 1988, p. 133), surfaces of constant ν are cap-cyclides with complicated equations (Moon and Spencer 1988, p. 133), and surfaces of constant ψ are half-planes

$$\tan \psi = \frac{y}{x}. \tag{7}$$

References

Eckhoff, J. "Helly, Radon, and Carathéodory Type Theorems." Ch. 2.1 in *Handbook of Convex Geometry* (Ed. P. M. Gruber and J. M. Wills). Amsterdam, Netherlands: North-Holland, pp. 389–448, 1993.

Carathéodory's Theorem

If Ω_1 and Ω_2 are bounded domains, $\partial\Omega_1$, $\partial\Omega_2$ are JORDAN CURVES, and $\varphi : \Omega_1 \to \Omega_2$ is a CONFORMAL MAPPING, then φ (respectively, φ^{-1}) extends one-to-one and continuously to $\partial\Omega_1$ (respectively, $\partial\Omega_2$).

Cardano's Formula

CUBIC EQUATION

Cardinal Addition

Let A and B be any sets with empty INTERSECTION, and let $|X|$ denote the CARDINAL NUMBER of a SET X. Then

$$|A| + |B| = |A \cup B|$$

(Ciesielski 1997, p. 68; Dauben 1990, p. 173; Rubin 1967, p. 274; Suppes 1972, pp. 112–113).

It is an interesting exercise to show that cardinal addition is WELL DEFINED. The main steps are to show that for any CARDINAL NUMBERS a and b, there exist disjoint sets A and B with CARDINAL NUMBERS a and b, and to show that if A and B are disjoint and C and D disjoint with $|A| = |C|$ and $|B| = |D|$ then $|A \cup B| = |C \cup D|$. The second of these is easy. The first is a little tricky and requires an appeal to the axioms of SET THEORY. Also, one needs to restrict the definition of cardinal to guarantee if a is a cardinal, then there is a set A satisfying $|A| = a$.

See also CARDINAL MULTIPLICATION, CARDINAL EXPONENTIATION

Suppes, P. *Axiomatic Set Theory.* New York: Dover, 1972.

Cardinal Comparison

For any sets A and B, their CARDINAL NUMBERS satisfy $|A| \leq |B|$ IFF there is a one-to-one function f from A into B (Rubin 1967, p. 266; Suppes 1972, pp. 94 and 116). It is easy to show this satisfies the reflexive and transitive axioms of a PARTIAL ORDER. However, it is difficult to show the antisymmetry property, whose proof is known as the SCHRÖDER-BERNSTEIN THEOREM. To show the trichotomy property, one must use the AXIOM OF CHOICE.

Although an order type can be defined similarly, it does not seem usual to do so.

See also SCHRÖDER-BERNSTEIN THEOREM

Cardinal Exponentiation

Let A and B be any sets, and let $|X|$ be the CARDINAL NUMBER of a set X. Then cardinal exponentiation is defined by

$$|A|^{|B|} = |\text{set of all function from } B \text{ into } A|$$

(Ciesielski 1997, p. 68; Dauben 1990, p. 174; Moore 1982, p. 37; Rubin 1967, p. 275, Suppes 1972, p. 116).

It is easy to show that the CARDINAL NUMBER of the POWER SET of A is $2^{|A|}$, sine $|\{0, 1\}| = 2$ and there is a natural BIJECTION between the SUBSETS of A and the functions from A into $\{0, 1\}$.

Cardinal Multiplication

Let A and B be any sets. Then the product of $|A|$ and $|B|$ is defined as the CARTESIAN PRODUCT

$$|A| * |B| = |A \times B|$$

(Ciesielski 1997, p. 68; Dauben 1990, p. 173; Moore 1982, p. 37; Rubin 1967, p. 274; Suppes 1972, pp. 114–115).

Cardinal Number

In common usage, a cardinal number is a number used in counting (a COUNTING NUMBER), such as 1, 2, 3, ...

In formal SET THEORY, a cardinal number (also called "the cardinality") is a type of number defined in such a way that any method of counting SETS using it gives the same result. (This is not true for the ORDINAL NUMBERS.) In fact, the cardinal numbers are obtained by collecting all ORDINAL NUMBERS which are obtainable by counting a given set. A set has $\aleph_0$ (ALEPH-0) members if it can be put into a ONE-TO-ONE correspondence with the finite ORDINAL NUMBERS. The cardinality of a set is also frequently referred to as the "power" of a set (Moore 1982, Dauben 1990, Suppes 1972).

In Cantor's original notation, the symbol for a SET A annotated with a single overbar $\bar{A}$ indicated A stripped of any structure besides order, hence it represented the ORDER TYPE of the set. A double overbar $\bar{\bar{A}}$ then indicated stripping the order from the set and thus indicated the cardinal number of the set. However, in modern notation, the symbol $|A|$ is used to denote the cardinal number of set.

Cantor, the father of modern SET THEORY, noticed that while the ORDINAL NUMBERS $\omega+1$, $\omega+2$, ... were bigger than omega in the sense of order, they were not bigger in the sense of EQUIPOLLENCE. This led him to study what would come to be called cardinal numbers. He called the ordinals ω, $\omega+1$, ... that are equipollent to the integers "the second number class" (as opposed to the finite ordinals, which he called the "first number class"). Cantor showed

1. The second number class is bigger than the first.
2. There is no class bigger than the first number class and smaller than the second.
3. The class of real numbers is bigger than the first number class.

One of the first serious mathematical definitions of cardinal was the one devised by Gottlob Frege and Bertrand Russell, who defined a cardinal number $|A|$ as the set of all sets EQUIPOLLENT to A. (Moore 1982, p. 153; Suppes 1972, p. 109). Unfortunately, the objects produced by this definition are not sets in the sense of ZERMELO-FRAENKEL SET THEORY, but rather "PROPER CLASSES" in the terminology of von Neumann.

Tarski (1924) proposed to instead define a cardinal number by stating that every set A is associated with a cardinal number $|A|$, and two sets A and B have the same cardinal number IFF they are EQUIPOLLENT (Moore 1982, pp. 52 and 214; Rubin 1967, p. 266; Suppes 1972, p. 111). The problem is that this definition requires a special axiom to guarantee that cardinals exist.

A. P. Morse and Dana Scott defined cardinal number by letting A be any set, then calling $|A|$ the set of all sets EQUIPOLLENT to A and of least possible RANK (Rubin 1967, p. 270).

It is possible to associate cardinality with a specific set, but the process required either the AXIOM OF FOUNDATION or the AXIOM OF CHOICE. However, these are two of the more controversial ZERMELO-FRAENKEL AXIOMS. With the AXIOM OF CHOICE, the cardinals can be enumerated through the ordinals. In fact, the two can be put into one-to-one correspondence. The AXIOM OF CHOICE implies that every set can be WELL ORDERED and can therefore be associated with an ORDINAL NUMBER.

This leads to the definition of cardinal number for a SET A as the least ORDINAL NUMBER b such that A and b are EQUIPOLLENT. In this model, the cardinal numbers are just the INITIAL ORDINALS. This definition obviously depends on the AXIOM OF CHOICE, because if the AXIOM OF CHOICE is not true, then there are sets that cannot be well ordered. Cantor believed that every set could be well ordered and used this correspondence to define the $\aleph$s ("alephs"). For any ORDINAL NUMBER α, $\aleph_\alpha = \omega_\alpha$.

An INACCESSIBLE CARDINAL cannot be expressed in terms of a smaller number of smaller cardinals.

Cardinality

CARDINAL NUMBER

Cardioid

The curve given by the POLAR equation

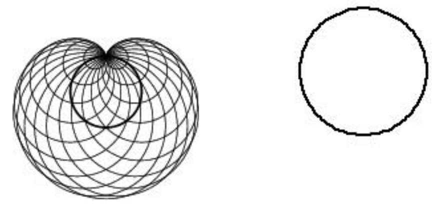
$$r = a(1+\cos\theta), \tag{1}$$

sometimes also written

$$r = 2b(1+\cos\theta), \tag{2}$$

where $b \equiv a/2$, the CARTESIAN equation

$$(x^2+y^2-ax)^2 = a^2(x^2+y^2), \tag{3}$$

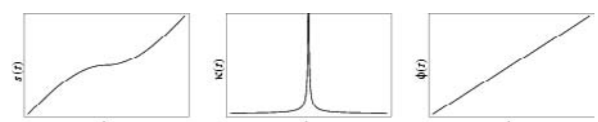


and the PARAMETRIC EQUATIONS

$$x = a\cos t(1+\cos t) \tag{4}$$

$$y = a\sin t(1+\cos t). \tag{5}$$

The cardioid is a degenerate case of the LIMAÇON. It is also a 1-CUSPED EPICYCLOID (with $r=r$) and is the CAUSTIC formed by rays originating at a point on the circumference of a CIRCLE and reflected by the CIRCLE.



the name cardioid was first used by de castillon in *philosophical transactions of the royal society* in 1741. its ARC LENGTH was found by la hire in 1708. there are exactly three PARALLEL TANGENTS to the cardioid with any given gradient. also, the TANGENTS at the ends of any CHORD through the CUSP point are at RIGHT ANGLES. The length of any CHORD through the CUSP point is $2a$.

The cardioid may also be generated as follows. Draw a CIRCLE C and fix a point A on it. Now draw a set of CIRCLES centered on the CIRCUMFERENCE of C and passing through A. The ENVELOPE of these CIRCLES is then a cardioid (Pedoe 1995). Let the CIRCLE C be centered at the origin and have RADIUS 1, and let the fixed point be $A=(1,\ 0)$. Then the RADIUS of a CIRCLE centered at an ANGLE θ from (1, 0) is

$$\begin{aligned} r^2 &= (0-\cos\theta)^2+(1-\sin\theta)^2 \\ &= \cos^2\theta+1-2\sin\theta+\sin^2\theta = 2(1-\sin\theta). \end{aligned} \tag{6}$$

If the fixed point A is not on the circle, then the resulting ENVELOPE is a LIMAÇON instead of a cardioid.

The ARC LENGTH, CURVATURE, and TANGENTIAL ANGLE are

$$s = \int_0^t 2|\cos(\tfrac{1}{2}t)|\,dt = 4a\sin(\tfrac{1}{2}\theta) \tag{7}$$

$$\kappa = \frac{3|\sec(\tfrac{1}{2}\theta)|}{4a} \tag{8}$$

$$\phi = \tfrac{3}{2}\theta. \tag{9}$$

As usual, care must be taken in the evaluation of $s(t)$ for $t>\pi$. Since (7) comes from an integral involving the ABSOLUTE VALUE of a function, it must be monotonic increasing. Each QUADRANT can be treated correctly by defining

$$n = \left\lfloor \frac{t}{\pi} \right\rfloor + 1, \tag{10}$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION, giving the formula

$$s(t) = (-1)^{1+[n \pmod 2]} 4\sin(\tfrac{1}{2}t) + 8\left\lfloor \tfrac{1}{2}n \right\rfloor. \tag{11}$$

The PERIMETER of the curve is

$$L = \int_0^{2\pi} |2a\cos(\tfrac{1}{2}\theta)|\,d\theta = 4a\int_0^{\pi}\cos(\tfrac{1}{2}\theta)\,d\theta$$
$$= 4a\int_0^{\pi/2}\cos\phi(2\,d\phi) = 8a\int_0^{\pi/2}\cos\phi\,d\phi$$
$$= 8a[\sin\phi]_0^{\pi/2} = 8a. \qquad (12)$$

The AREA is

$$A = \tfrac{1}{2}\int_0^{2\pi} r^2\,d\theta = \tfrac{1}{2}a^2\int_0^{2\pi}(1+2\cos\theta+\cos^2\theta)\,d\theta$$
$$= \tfrac{1}{2}a^2\int_0^{2\pi}\{1+2\cos\theta+\tfrac{1}{2}[1+\cos(2\theta)]\}\,d\theta$$
$$= \tfrac{1}{2}a^2\int_0^{2\pi}[\tfrac{3}{2}+2\cos\theta+\tfrac{1}{2}\cos(2\theta)]\,d\theta$$
$$= \tfrac{1}{2}a^2[\tfrac{3}{2}\theta+2\sin\theta+\tfrac{1}{4}\sin(2\theta)]_0^{2\pi} = \tfrac{3}{2}\pi a^2. \qquad (13)$$

Cardioid Caustic

The CATACAUSTIC of a CARDIOID for a RADIANT POINT at the CUSP is a NEPHROID. The CATACAUSTIC for PARALLEL rays crossing a CIRCLE is a CARDIOID.

Cardioid Coordinates

A coordinate system (μ, ν, ψ) defined by the coordinate transformation

$$x = \frac{\mu\nu}{(\mu^2+\nu^2)^2}\cos\psi \qquad (1)$$

$$y = \frac{\mu\nu}{(\mu^2+\nu^2)^2}\sin\psi \qquad (2)$$

$$z = \frac{1}{2}\frac{\nu^2-\nu^2}{(\mu^2+\nu^2)^2} \qquad (3)$$

with $\mu,\ \nu \le 0$ and $\psi \in [0, 2\pi)$. Surfaces of constant μ are given by the cardioids of revolution intersecting the positive half of the z-axis

$$x^2+y^2+z^2 = \frac{1}{4\mu^2}[\sqrt{x^2+y^2+z^2}+1], \qquad (4)$$

surfaces of constant ν by the cardioids of revolution intersecting the negative half of the z-axis

$$x^2+y^2+z^2 = \frac{1}{4\nu^2}[\sqrt{x^2+y^2+z^2}-z], \qquad (5)$$

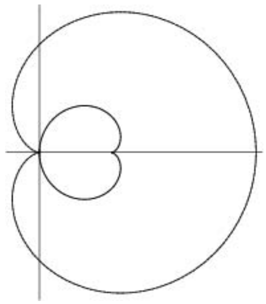
and surfaces of constant ψ by the half-planes

$$\tan\psi = \frac{y}{x}. \qquad (6)$$

The metric coefficients are

$$g_{\mu\mu} = \frac{1}{(\mu^2+\nu^2)^3} \qquad (7)$$

$$g_{\nu\nu} = \frac{1}{(\mu^2+\nu^2)^3} \qquad (8)$$



$$g_{\psi\psi} = \frac{\mu^2\nu^2}{(\mu^2+\nu^2)^4} \qquad (9)$$

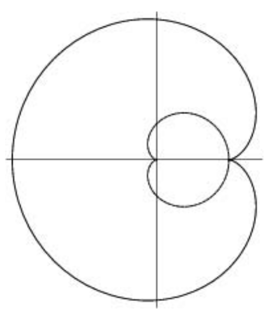
Cardioid Evolute

$$x = \tfrac{2}{3}a + \tfrac{1}{3}a\cos\theta(1-\cos\theta)$$



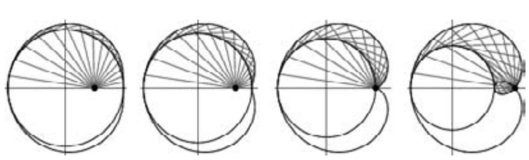
$$y = \tfrac{1}{3}a\sin\theta(1-\cos\theta).$$

This is a mirror-image CARDIOID with $a' = a/3$.

Cardioid Inverse Curve

If the CUSP of the cardioid is taken as the INVERSION CENTER, the cardioid inverts to a PARABOLA.

Cardioid Involute



$$x = 2a + 3a\cos\theta(1-\cos\theta)$$

$$y = 3a\sin\theta(1-\cos\theta).$$

This is a mirror-image CARDIOID with $a' = 3a$.

Cardioid Pedal Curve

The PEDAL CURVE of the CARDIOID where the PEDAL POINT is the CUSP is CAYLEY'S SEXTIC.

Cards

Cards are a set of n rectangular pieces of cardboard with markings on one side and a uniform pattern on the other. The collection of all cards is called a "deck," and a normal deck of cards consists of 52 cards having 14 distinct values for each of four different "suits." The suits are called clubs (♣), diamonds (♢), hearts (♡), and spades (♠). Spades and clubs are colored black, while hearts and diamonds are colored red. The cards of each suit are numbered 1 through 13, where the special terms ace (1), jack (11), queen (12), and king (13) are used instead of numbers 1 and 11–13. However, in BRIDGE and a number of other games, the ace is considered the *highest* card, and so would be assigned a value of 14 instead of 1.

The randomization of the order of cards in a deck is called SHUFFLING. Cards are used in many gambling games (such as POKER), and the investigation of the probabilities of various outcomes in card games was one of the original motivations for the development of modern PROBABILITY theory.

Carleman's Inequality

Let $\{a_i\}_{i=1}^n$ be a SET of POSITIVE numbers. Then

$$\sum_{i=1}^n (a_1 a_2 \ldots a_i)^{1/i} \leq e \sum_{i=1}^n a_i$$

(which is given incorrectly in Gradshteyn and Ryzhik 1994). Here, the constant e is the best possible, in the sense that counterexamples can be constructed for any stricter INEQUALITY which uses a smaller constant. The theorem is suggested by writing $a_i' = a_i^p$ in HARDY'S INEQUALITY

$$\sum_{i=1}^n \left(\frac{a_1 + \ldots + a_i}{i}\right)^p < \left(\frac{p}{p-1}\right)^p \sum_{i=1}^n a_i^p \tag{1}$$

and letting $p \to \infty$.

Carlson-Levin Constant

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Assume that f is a NONNEGATIVE REAL function on $[0, \infty)$ and that the two integrals

$$\int_0^\infty x^{p-1-\lambda}[f(x)]^p\,dx \tag{1}$$

$$\int_0^\infty x^{q-1+\mu}[f(x)]^q\,dx \tag{2}$$

exist and are FINITE. If $p = q = 2$ and $\lambda = \mu = 1$, Carlson (1934) determined

$$\int_0^\infty f(x)\,dx \leq \sqrt{\pi}\left(\int_0^\infty [f(x)]^2\,dx\right)^{1/4}\left(\int_0^\infty x^2[f(x)]^2\,dx\right)^{1/4} \tag{3}$$

and showed that $\sqrt{\pi}$ is the best constant (in the sense that counterexamples can be constructed for any stricter INEQUALITY which uses a smaller constant). For the general case

$$\int_0^\infty f(x)\,dx \leq C\left(\int_0^\infty x^{p-1-\lambda}[f(x)]^p\,dx\right)^s\left(\int_0^\infty x^{q-1+\mu}[f(x)]^q\,dx\right)^t, \tag{4}$$

and Levin (1948) showed that the best constant

$$C = \frac{1}{(ps)^s(qt)^t}\left[\frac{\Gamma\left(\frac{s}{\alpha}\right)\Gamma\left(\frac{t}{\alpha}\right)}{(\lambda+\mu)\Gamma\left(\frac{s+t}{\alpha}\right)}\right]^\alpha, \tag{5}$$

where

$$s \equiv \frac{\mu}{p\mu + q\lambda} \tag{6}$$

$$t \equiv \frac{\lambda}{p\mu + q\lambda} \tag{7}$$

$$\alpha \equiv 1 - s - t \tag{8}$$

and $\Gamma(z)$ is the GAMMA FUNCTION.

Carlyle Circle

Consider a QUADRATIC EQUATION $x^2 - sx + p = 0$ where s and p denote *signed* lengths. The CIRCLE which has the points $A = (0,\ 1)$ and $B = (s,\ p)$ as a DIAMETER is then called the Carlyle circle $C_{s,p}$ of the equation. The CENTER of $C_{s,p}$ is then at the MIDPOINT of AB, $M = (s/2,\ (1+p)/2)$, which is also the MIDPOINT of $S = (s,\ 0)$ and $Y = (0,\ 1+p)$. Call the points at which $C_{s,p}$ crosses the X-AXIS $H_1 = (x_1,\ 0)$ and $H_2 = (x_2,\ 0)$ (with $x_1 \geq x_2$). Then

$$s = x_1 + x_2$$

$$p = x_1 x_2$$

$$(x - x_1)(x - x_2) = x^2 - sx + p,$$

so x_1 and x_2 are the ROOTS of the quadratic equation.

Carmichael Condition

A number n satisfies the Carmichael condition IFF $(p-1)|(n/p-1)$ for all PRIME DIVISORS p of n. This is equivalent to the condition $(p-1)|(n-1)$ for all PRIME DIVISORS p of n.

See also CARMICHAEL NUMBER

References

Carmichael Function

There are two definitions of the Carmichael function. One is the reduced totient function (also called the least universal exponent function), defined as the smallest integer m such that $k^n \equiv 1 \pmod{n}$ for all k RELATIVELY PRIME to n. The ORDER of $a \pmod{n}$ is at most $\lambda(n)$ (Ribenboim 1989). The first few values of this function, implemented in *Mathematica* 4.0 as `CarmichaelLambda[n]`, are 1, 1, 2, 2, 4, 2, 6, 2, 6, 4, 10, ... (Sloane's A002322). It can be defined recursively as

$$\lambda(n) = \begin{cases} \phi(n) & \text{for } n = p^\alpha,\ p = 2 \text{ and } \alpha \leq 2, \text{ or } p \geq 3 \\ \frac{1}{2}\phi(n) & \text{for } n = 2^\alpha \text{ and } \alpha \geq 3 \\ \text{LCM}[\lambda(p_i^{\alpha_i})]_i & \text{for } n = \prod_i p_i^{\alpha_i}. \end{cases}$$

Some special values are

$$\lambda(1) = 1$$

$$\lambda(2) = 1$$

$$\lambda(4) = 2$$

$$\lambda(2^r) = 2^{r-2}$$

for $r \geq 3$, and

$$\lambda'(p^r) = \phi(p^r)$$

for p an ODD PRIME and $r \geq 1$.

The second Carmichael's function $\lambda'(n)$ is given by the LEAST COMMON MULTIPLE (LCM) of all the FACTORS of the TOTIENT FUNCTION $\phi(n)$, except that if $8|n$, then $2^{\alpha-2}$ is a FACTOR instead of $2^{\alpha-1}$. The values of $\lambda'(n)$ for the first few n are 1, 1, 2, 2, 4, 2, 6, 4, 6, 4, 10, 2, 12, ... (Sloane's A011773).

Carmichael Lambda

CARMICHAEL FUNCTION

Carmichael Number

A Carmichael number is an ODD COMPOSITE NUMBER n which satisfies FERMAT'S LITTLE THEOREM

$$a^{n-1} - 1 \equiv 0 \pmod{n} \tag{1}$$

for *every* choice of a satisfying $(a, n) = 1$ (i.e., a and n are RELATIVELY PRIME) with $1 < a < n$. A Carmichael number is therefore a PSEUDOPRIME to any base. Carmichael numbers therefore cannot be found to be COMPOSITE using FERMAT'S LITTLE THEOREM. However, if $(a, n) \neq 1$, the congruence of FERMAT'S LITTLE THEOREM is sometimes NONZERO, thus identifying a Carmichael number n as COMPOSITE.

Carmichael numbers are sometimes called "absolute pseudoprimes" and also satisfy KORSELT'S CRITERION. R. D. Carmichael first noted the existence of such numbers in 1910, computed 15 examples, and conjectured that there were infinitely many. In 1956, Erdos sketched a technique for constructing large Carmichael numbers (Hoffman 1998, p. 183), and a proof was given by Alford *et al.* (1994).

The first few Carmichael numbers are 561, 1105, 1729, 2465, 2821, 6601, 8911, 10585, 15841, 29341, ... (Sloane's A002997). The number of Carmichael numbers less than 10^2, 10^3, ... are 0, 1, 7, 16, 43, 105, ... (Sloane's A055553; Pinch 1993). The smallest Carmichael numbers having 3, 4, ... factors are $561 = 3 \times 11 \times 17$, $41041 = 7 \times 11 \times 13 \times 41$, 825265, 321197185, ... (Sloane's A006931).

Carmichael numbers have at least three PRIME FACTORS. For Carmichael numbers with exactly three PRIME FACTORS, once one of the PRIMES has been specified, there are only a finite number of Carmichael numbers which can be constructed. Indeed, for Carmichael numbers with k prime factors, there are only a finite number with the least $k-2$ specified.

Numbers OF THE FORM $(6k+1)(12k+1)(18k+1)$ are Carmichael numbers if each of the factors is PRIME (Korselt 1899, Ore 1988, Guy 1994). This can be seen since for

$$\begin{aligned} N &\equiv (6k+1)(12k+1)(18k+1) \\ &= 1296k^3 + 396k^2 + 36k + 1, \end{aligned} \tag{2}$$

$N-1$ is a multiple of $36k$ and the LEAST COMMON MULTIPLE of $6k$, $12k$, and $18k$ is $36k$, so $a^{N-1} \equiv 1$ modulo each of the PRIMES $6k+1$, $12k+1$, and $18k+1$, hence $a^{N-1} \equiv 1$ modulo their product. The first few such Carmichael numbers correspond to $k = 1$, 6, 35, 45, 51, 55, 56, ... (Sloane's A046025) and are 1729, 294409, 56052361, 118901521, ... (Sloane's A033502). In Jan. 1999, Dubner found the largest known Carmichael of this form, having 4848 digits and index

$$k = 133752260 \cdot 3003 \cdot 10^{1604} \tag{3}$$

The prime factors of N have 1616, 1616, and 1617 digits.

Let $C(n)$ denote the number of Carmichael numbers less than n. Then, for all sufficiently large n,

$$C(n) > n^{2/7} \tag{4}$$

(Alford *et al.* 1994), which proves that there are infinitely many Carmichael numbers. The upper bound

$$C(n) < n \exp\left(\frac{\ln n \ln \ln \ln n}{\ln \ln n}\right) \tag{5}$$

has also been proved (R. G. E. Pinch).

The Carmichael numbers have the following properties:

1. If a PRIME p divides the Carmichael number n, then $n \equiv 1 \pmod{p-1}$ implies that $n \equiv p \pmod{p(p-1)}$.
2. Every Carmichael number is SQUAREFREE.
3. An ODD COMPOSITE SQUAREFREE number n is a Carmichael number IFF n divides the DENOMINATOR of the BERNOULLI NUMBER B_{n-1}.

The largest known Carmichael numbers having a given number of factors are summarized in the following table (Dubner 1989, Dubner 1998).

Factors	Digits	Discoverer
3	10200	Dubner
4	2467	Caldwell and Dubner
5	1015	Caldwell and Dubner
6	827	Caldwell and Dubner

Carmichael Sequence

A FINITE, INCREASING SEQUENCE of INTEGERS $\{a_1, \ldots, a_m\}$ such that

$$(a_i - 1)|(a_1 \ldots a_{i-1})$$

for $i = 1, \ldots, m$, where $m|n$ indicates that m DIVIDES n. A Carmichael sequence has exclusive EVEN or ODD elements. There are infinitely many Carmichael sequences for every order.

Carmichael's Theorem

If a and n are RELATIVELY PRIME so that the GREATEST COMMON DIVISOR $\text{GCD}(a, n) = 1$, then

$$a^{\lambda(n)} \equiv 1 \pmod{n}$$

where λ is the CARMICHAEL FUNCTION.

Carmichael's Totient Function Conjecture

It is thought that the TOTIENT VALENCE FUNCTION $N_\phi(n) \geq 2$, i.e., if there is an n such that $\phi(x) = n$, then there are at least two solutions x. This assertion is called Carmichael's totient function conjecture and is equivalent to the statement that there exists an $m \neq n$ such that $\phi(n) = \phi(m)$ (Ribenboim 1996, pp. 39–40).

Dickson 1952 (p. 137) states that the conjecture was proved by Carmichael (1907), who also developed a method of finding the solution (Carmichael 1909). The result also appears as in exercise in Carmichael (1914). However, Carmichael (1922) subsequently discovered an error in the proof, and the conjecture currently remain open. Any counterexample to the conjecture must have more than 10,000,000 DIGITS (Schlafly and Wagon 1994; conservatively given as 10,000 in Conway and Guy 1996, p. 155).

Ford (1998ab) showed that if there is a counterexample to Carmichael's conjecture, then a positive proportion of totients are counterexamples.

SIERPINSKI'S CONJECTURE states that all integers > 1 appear as multiplicities of the TOTIENT VALENCE FUNCTION.

Carnot's Polygon Theorem

If a PLANE cuts the sides AB, BC, CD, and DA of a SKEW QUADRILATERAL $ABCD$ in points P, Q, R, and S, then

$$\frac{AP}{PB}\cdot\frac{BQ}{QC}\cdot\frac{CR}{RD}\cdot\frac{DS}{SA}=1$$

both in magnitude and sign (Altshiller-Court 1979, p. 111).

More generally, if P_1, P_2, ..., are the VERTICES of a finite POLYGON with no "minimal sides" and the side P_iP_j meets a curve in the POINTS P_{ij1} and P_{ij2}, then

$$\frac{\prod_i \overline{P_1P_{12i}}\ \prod_i \overline{P_2P_{23i}}\ \cdots\ \prod_i \overline{P_NP_{N1i}}}{\prod_i \overline{P_NP_{N1i}}\ \cdots\ \prod_i \overline{P_2P_{2i1}}}=1,$$

where $\overline{AB}$ denotes the DISTANCE from POINT A to B.

Carotid-Kundalini Fractal

A fractal-like structure is produced for $x<0$ by superposing plots of CAROTID-KUNDALINI FUNCTIONS ck_n of different orders n. the region $-1<x<0$ is called FRACTAL LAND by pickover (1995), the central region the GAUSSIAN MOUNTAIN RANGE, and the region $0<x<1$ OSCILLATION LAND. The plot above shows $n=1$ to 25. Gaps in FRACTAL LAND occur whenever

$$x\cos^{-1}x=2\pi\frac{p}{q}$$

for p and q RELATIVELY PRIME INTEGERS. At such points x, the functions assume the $\lceil (q+1)/2\rceil$ values $\cos(2\pi r/q)$ for $r=0, 1, ..., \lfloor q/2\rfloor$, where $\lceil z\rceil$ is the CEILING FUNCTION and $\lfloor z\rfloor$ is the FLOOR FUNCTION.

Cartan Decomposition

References

Huang, J.-S. "Linear Reductive Groups and Cartan Decomposition." §10.1 in *Lectures on Representation Theory.* Singapore: World Scientific, pp. 129–130, 1999.

Cartan Matrix

A Cartan matrix is a SQUARE INTEGER MATRIX who elements (A_{ij}) satisfy the following conditions.

1. A_{ij} is an integer, one of $\{-3, -2, -1, 0, 2\}$.
2. $A_{ii} = 2$ the diagonal entries are all 2.
3. $A_{ij} \leq 0$ off of the diagonal.
4. $A_{ij} = 0$ iff $A_{ji} = 0$.
5. There exists a DIAGONAL MATRIX D such that DAD^{-1} gives a SYMMETRIC and POSITIVE DEFINITE QUADRATIC FORM.

A Cartan matrix can be associated to a SEMISIMPLE LIE ALGEBRA $\mathfrak{g}$. It is a $k \times k$ SQUARE MATRIX, where k is the RANK of $\mathfrak{g}$. The SIMPLE ROOTS are the basis vectors, and A_{ij} is determined by their inner product, using the KILLING FORM.

$$A_{ij} = 2\langle \alpha_i, \alpha_j \rangle / \langle \alpha_j, \alpha_j \rangle \tag{1}$$

In fact, it is more a table of values than a matrix. By reordering the basis vectors, one gets another Cartan matrix, but it is considered equivalent to the original Cartan matrix.

The Lie algebra $\mathfrak{g}$ can be reconstructed, up to ISOMORPHISM, by the $3k$ generators $\{e_j, f_i, h_i\}$ which satisfy the SERRE RELATIONS. In fact,

$$\mathfrak{g} = \mathfrak{h} \oplus \mathfrak{e} \oplus \mathfrak{f} \tag{2}$$

where $\mathfrak{h}$, $\mathfrak{e}$, $\mathfrak{f}$ are the LIE SUBALGEBRAS generated by the generators of the same letter.

For example,

$$A = \begin{bmatrix} 2 & -1 \\ -1 & 2 \end{bmatrix} \tag{3}$$

is a Cartan matrix. The LIE ALGEBRA $\mathfrak{g}$ has six generators $\{h_1, h_2, e_1, e_2, f_1, f_2\}$. They satisfy the following relations.

1. $[h_1, h_2] = 0$.
2. $[e_1, f_1] = h_1$ and $[e_2, f_2] = h_2$ while $[e_1, f_2] = [e_2, f_1] = 0$.
3. $[h_i, e_j] = -A_{ij} e_j$.
4. $[h_i, f_j] = -A_{ij} f_j$.
5. $e_{12} = [e_1, e_2] \neq 0$ and $f_{12} = [f_1, f_2] \neq 0$.
6. $[e_i, e_{12}] = 0$ and $[f_i, f_{12}] = 0$.

From these relations, it is not hard to see that $\mathfrak{g} = \mathfrak{sl}_3$ with the standard REPRESENTATION

$$h_1 = \begin{bmatrix} 1 & 0 & 1 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{bmatrix} \tag{4}$$

$$h_2 = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -1 \end{bmatrix} \tag{5}$$

$$e_1 = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \tag{6}$$

$$e_2 = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix} \tag{7}$$

$$e_{12} = \begin{bmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \tag{8}$$

$$f_1 = \begin{bmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \tag{9}$$

$$f_2 = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix} \tag{10}$$

$$f_{12} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ -1 & 0 & 0 \end{bmatrix}. \tag{11}$$

In addition, the WEYL GROUP can be constructed directly from the Cartan matrix. Its rows determine the reflections against the simple roots. The following Mathematica command converts a Cartan matrix to a list of generators for the Weyl group, in its representation on the ROOT LATTICE. In particular, its output represents the matrices of the Weyl group as INTEGER MATRICES.

Cartesian Coordinates

Cartesian coordinates are rectilinear 2-D or 3-D coordinates (and therefore a special case of CURVILINEAR COORDINATES) which are also called rectangular coordinates. The three axes of 3-D Cartesian coordinates, conventionally denoted the X-, Y-, and Z-AXES (a NOTATION due to Descartes) are chosen to be linear and mutually PERPENDICULAR. In 3-D, the coordinates x, y, and z may lie anywhere in the INTERVAL $(-\infty, \infty)$.

The INVERSION of 3-D Cartesian is called 6-SPHERE COORDINATES coordinates.

The SCALE FACTORS of Cartesian coordinates are all unity, $h_i = 1$. The LINE ELEMENT is given by

$$d\mathbf{s} = dx\,\hat{\mathbf{x}} + dy\,\hat{\mathbf{y}} + dz\,\hat{\mathbf{z}}, \tag{1}$$

and the VOLUME ELEMENT by

$$dV = dx\,dy\,dz. \tag{2}$$

The GRADIENT has a particularly simple form,

$$\nabla \equiv \hat{\mathbf{x}}\frac{\partial}{\partial x} + \hat{\mathbf{y}}\frac{\partial}{\partial y} + \hat{\mathbf{z}}\frac{\partial}{\partial z}, \tag{3}$$

as does the LAPLACIAN

$$\nabla^2 \equiv \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2}. \tag{4}$$

The LAPLACIAN is

$$\begin{aligned}\nabla^2\mathbf{F} \equiv \nabla\cdot(\nabla\mathbf{F}) &= \frac{\partial^2\mathbf{F}}{\partial x^2} + \frac{\partial^2\mathbf{F}}{\partial y^2} + \frac{\partial^2\mathbf{F}}{\partial z^2}\\ &= \hat{\mathbf{x}}\left(\frac{\partial^2 F_x}{\partial x^2} + \frac{\partial^2 F_x}{\partial y^2} + \frac{\partial^2 F_x}{\partial z^2}\right)\\ &\quad + \hat{\mathbf{y}}\left(\frac{\partial^2 F_y}{\partial x^2} + \frac{\partial^2 F_y}{\partial y^2} + \frac{\partial^2 F_y}{\partial z^2}\right)\\ &\quad + \hat{\mathbf{z}}\left(\frac{\partial^2 F_z}{\partial x^2} + \frac{\partial^2 F_z}{\partial y^2} + \frac{\partial^2 F_z}{\partial z^2}\right).\end{aligned} \tag{5}$$

The DIVERGENCE is

$$\nabla\cdot\mathbf{F} = \frac{\partial F_x}{\partial x} + \frac{\partial F_y}{\partial y} + \frac{\partial F_z}{\partial z}, \tag{6}$$

and the CURL is

$$\begin{aligned}\nabla\times\mathbf{F} \equiv \begin{vmatrix}\hat{\mathbf{x}} & \hat{\mathbf{y}} & \hat{\mathbf{z}}\\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z}\\ F_x & F_y & F_z\end{vmatrix} &= \left(\frac{\partial F_z}{\partial y} - \frac{\partial F_y}{\partial z}\right)\hat{\mathbf{x}} + \left(\frac{\partial F_x}{\partial z} - \frac{\partial F_z}{\partial x}\right)\hat{\mathbf{y}}\\ &\quad + \left(\frac{\partial F_y}{\partial x} - \frac{\partial F_x}{\partial y}\right)\hat{\mathbf{z}}.\end{aligned} \tag{7}$$

The GRADIENT of the DIVERGENCE is

$$\begin{aligned}\nabla(\nabla\cdot\mathbf{u}) &= \begin{bmatrix}\frac{\partial}{\partial x}\left(\frac{\partial u_z}{\partial x} + \frac{\partial u_y}{\partial y} + \frac{\partial u_z}{\partial z}\right)\\ \frac{\partial}{\partial y}\left(\frac{\partial u_z}{\partial x} + \frac{\partial u_y}{\partial y} + \frac{\partial u_z}{\partial z}\right)\\ \frac{\partial}{\partial z}\left(\frac{\partial u_z}{\partial x} + \frac{\partial u_y}{\partial y} + \frac{\partial u_z}{\partial z}\right)\end{bmatrix}\\ &= \begin{bmatrix}\frac{\partial}{\partial x}\\ \frac{\partial}{\partial y}\\ \frac{\partial}{\partial z}\end{bmatrix}\left(\frac{\partial u_x}{\partial x} + \frac{\partial u_y}{\partial y} + \frac{\partial u_z}{\partial z}\right).\end{aligned} \tag{8}$$

LAPLACE'S EQUATION is separable in Cartesian coordinates.

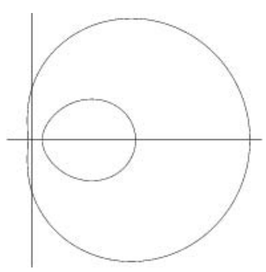
Cartesian Geometry



The use of coordinates (such as CARTESIAN COORDINATES) in the study of GEOMETRY. Cartesian geometry is named after René Descartes (Bell 1986, p. 48), although Descartes may have been anticipated by Fermat (Coxeter and Greitzer 1967, p. 31).

Cartesian Ovals

A curve consisting of two ovals which was first studied by Descartes in 1637. It is the locus of a point P whose distances from two FOCI F_1 and F_2 in two-center BIPOLAR COORDINATES satisfy

$$mr \pm nr' = k, \tag{1}$$

where m, n are POSITIVE INTEGERS, k is a POSITIVE real, and r and r' are the distances from F_1 and F_2. If $m = n$, the oval becomes an ELLIPSE. In CARTESIAN COORDINATES, the Cartesian ovals can be written

$$m\sqrt{(x-a)^2+y^2} + n\sqrt{(x+a)^2+y^2} = k^2 \tag{2}$$

$$(x^2+y^2+a^2)(m^2-n^2) - 2ax(m^2+n^2) - k^2 = -2n\sqrt{(x+a)^2+y^2}, \tag{3}$$

$$[(m^2-n^2)(x^2+y^2+a^2) - 2ax(m^2+n^2)]^2 = 2(m^2+n^2)(n^2+y^2+a^2) - 4ax(m^2-n^2) - k^2. \tag{4}$$

Now define

$$b \equiv m^2 - n^2 \tag{5}$$

$$c \equiv m^2 + n^2, \tag{6}$$

and set $a = 1$. Then

$$[b(x^2+y^2) - 2cx + b]^2 + 4bx + k^2 - 2c = 2c(x^2+y^2). \tag{7}$$

If c' is the distance between F_1 and F_2, and the equation

$$r + mr' = a \tag{8}$$

is used instead, an alternate form is

$$[(1-m^2)(x^2+y^2) + 2m^2c'x + a'^2 - m^2c'^2]^2 = 4a'^2(x^2+y^2). \tag{9}$$

The curves possess three FOCI. If $m = 1$, one Cartesian oval is a central CONIC, while if $m = a/c$, then the curve is a LIMAÇON and the inside oval touches the outside one. Cartesian ovals are ANALLAGMATIC CURVES.

Cartesian Product

The Cartesian product of two sets A and B (also called the product set, set direct product, or cross product) is defined to be the set of all points (a, b) where $a \in A$ and $b \in B$. It is denoted $A \times B$, and is called the Cartesian product since it originated in Descartes' formulation of analytic geometry. In the Cartesian view, points in the plane are specified by their vertical and horizontal coordinates, with points on a line being specified by just one coordinate. The main examples of direct products are EUCLIDEAN 3-space ($\mathbb{R} \times \mathbb{R} \times \mathbb{R}$, where $\mathbb{R}$ are the REAL NUMBERS), and the plane ($\mathbb{R} \times \mathbb{R}$).

The GRAPH PRODUCT is sometimes called the Cartesian product (Vizing 1963, Cark and Suen 2000).

Casey's Theorem
Four CIRCLES c_1, c_2, c_3, and c_4 are TANGENT to a fifth CIRCLE or a straight LINE IFF

$$T_{12}T_{34} \pm T_{13}T_{42} \pm T_{14}T_{23} = 0. \qquad (1)$$

where T_{ij} is the length of a common TANGENT to CIRCLES i and j (Johnson 1929, pp. 121–122). The following cases are possible:

1. If all the Ts are direct common tangents, then c_5 has like contact with all the circles,
2. If the Ts from one circle are transverse while the other three are direct, then this one circle has contact with c_5 unlike that of the other three,
3. If the given circles can be so paired that the common tangents to the circles of each pair are direct, while the other four are transverse, then the members of each pair have like contact with c_5

(Johnson 1929, p. 125).

The special case of Casey's theorem shown above was given in a SANGAKU PROBLEM from 1874 in the Gumma Prefecture. In this form, a single circle is drawn inside a square, and four circles are then drawn around it, each of which is tangent to the square on two of its sides. For a square of side length a with lower left corner at $(0,\ 0)$ containing a central circle of radius r with center $(x,\ y)$, the radii and positions of the four circles can be found by solving

$$(1-r_4-x)^2+(y-r_4)^2=(r+r_4)^2 \qquad (2)$$

$$(1-r_1-x)^2+(1-r_1-y)^2=(r+r_1)^2 \qquad (3)$$

$$(x-r_3)^2+(y-r_3)^2+(r+r_3)^2 \qquad (4)$$

$$(x-r_2)^2+(1-r_2-y)^2=(r+r_2)^2. \qquad (5)$$

Four of the T_{ij} for the theorem are given immediately for the figure as

$$T_{12}=a-r_1-r_2 \qquad (6)$$

$$T_{34}=a-r_r-r_4 \qquad (7)$$

$$T_{14}=a-r_1-r_4 \qquad (8)$$

$$T_{23}=a-r_2-r_3. \qquad (9)$$

The remaining T_{13} and T_{24} can be found as shown in the above right figure. Let c_{ij} be the distance from O_i to O_j, then

$$c_{13}^2=(a-r_1-r_3)^2+(a-r_1-r_3)^2=2(a-r_1-r_3)^2 \qquad (10)$$

$$c_{24}^2=(a-r_2-r_4)^2+(a-r_2-r_4)^2 = 2(a-r_2-r_4)^2, \qquad (11)$$

so

$$T_{13}=\sqrt{c_{13}^2-(r_3-r_1)^2} = \sqrt{2(a-r_1-r_3)^2-(r_3-r_1)^2} \qquad (12)$$

$$T_{24}=\sqrt{c_{24}^2-(r_2-r_4)^2} = \sqrt{2(a-r_2-r_4)^2-(r_2-r_4)^2}. \qquad (13)$$

Since the four circles are all externally tangent to c_5, the relevant form of Casey's theorem to use has signs $(+,\ -)$, so we have the equation

$$(a-r_1-r_2)(a-r_3-r_4)+(a-r_1-r_4)(a-r_2-r_3) -\sqrt{[2(a-r_1-r_3)^2-(r_3-r_1)^2][2(a-r_2-r_4)^2-(r_2-r_4)^2]}=0 \qquad (14)$$

(Rothman 1998). Solving for a then gives the relationship

$$a=\frac{2(r_1r_3-r_2r_4)+\sqrt{2(r_1-r_2)(r_1-r_4)(r_3-r_2)(r_3-r_4)}}{r_1-r_2+r_3-r_4} \qquad (15)$$

Durell (1928) calls the following Casey's theorem: if t is the length of a common tangent of two circles of radii a and b, t' is the length of the corresponding common tangent of their inverses with respect to any point, and a' and b' are the radii of their inverses,

then

$$\frac{t^2}{ab} = \frac{t'^2}{a'b'}. \quad (16)$$

Casoratian

The Casoratian of sequences $x_n^{(1)}, x_n^{(2)}, ..., x_n^{(k)}$ is defined by the $k \times k$ DETERMINANT

$$C(x_n^{(1)}, x_n^{(2)}, x_n^{(k)}) = \begin{vmatrix} x_n^{(1)} & x_n^{(2)} & \cdots & x_n^{(k)} \\ x_{n+1}^{(1)} & x_{n+1}^{(2)} & \cdots & x_{n+1}^{(k)} \\ \vdots & \vdots & \ddots & \vdots \\ x_{n+k-1}^{(1)} & x_{n+k-1}^{(2)} & \cdots & x_{n+k-1}^{(k)} \end{vmatrix}.$$

The solutions $x_n^{(1)}, x_n^{(2)}, ..., x_n^{(k)}$ of the linear difference equation

$$x_{n+k} + b_n^{(k-1)} x_{n+(k-1)} + \ldots + b_n^{(1)} x_{n+1} + b_n^{(0)} x_n = 0$$

for $n = 0, 1, ...$, are linearly independent sequences IFF their Casoratian is nonzero for $n = 0$ (Zwillinger 1995).

Casorati-Weierstrass Theorem

WEIERSTRASS-CASORATI THEOREM

Cassini Ellipses

CASSINI OVALS

Cassini Ovals

The curves, also called Cassini ellipses, described by a point such that the product of its distances from two fixed points a distance $2a$ apart is a constant b^2. The shape of the curve depends on b/a. If $a < b$, the curve is a single loop with an OVAL (left figure above) or dog bone (second figure) shape. The case $a = b$ produces a LEMNISCATE (third figure). If $a > b$, then the curve consists of two loops (right figure). Cassini ovals are ANALLAGMATIC CURVES.

The curve was first investigated by Cassini in 1680 when he was studying the relative motions of the Earth and the Sun. Cassini believed that the Sun traveled around the Earth on one of these ovals, with the Earth at one FOCUS of the oval.

The Cassini ovals are defined in two-center BIPOLAR COORDINATES by the equation

$$r_1 r_2 = b^2, \quad (1)$$

with the origin at a FOCUS. Even more incredible curves are produced by the locus of a point the product of whose distances from 3 or more fixed points is a constant.

The Cassini ovals have the CARTESIAN equation

$$[(x-a)^2 + y^2][(x+a)^2 + y^2] = b^4 \quad (2)$$

or the equivalent form

$$(x^2 + y^2 + a^2)^2 - 4a^2x^2 = b^4 \quad (3)$$

and the polar equation

$$r^4 + a^4 - 2a^2r^2 \cos(2\theta) = b^4. \quad (4)$$

Solving for r^2 using the QUADRATIC EQUATION gives

$$r^2 = \frac{2a^2\cos(2\theta) \pm \sqrt{4a^4\cos^2(2\theta) - 4(a^4 - b^4)}}{2}$$
$$= a^2\cos(2\theta) \pm \sqrt{a^4\cos^2(2\theta) + b^4 - a^4}$$
$$= a^2\cos(2\theta) \pm \sqrt{a^4[\cos^2(2\theta) - 1] + b^4}$$
$$= a^2\cos(2\theta) \pm \sqrt{b^4 - a^4\sin^2(2\theta)}$$
$$= a^2\left[\cos(2\theta) \pm \sqrt{\left(\frac{b}{a}\right)^4 - \sin^2(2\theta)}\right]. \quad (5)$$

Let a TORUS of tube radius a be cut by a plane perpendicular to the plane of the torus's centroid. Call the distance of this plane from the center of the torus hole r, let $a = r$, and consider the intersection of this plane with the torus as r is varied. The resulting curves are Cassini ovals, with a LEMNISCATE occurring at $r = 1/2$ (Gosper). Cassini ovals are therefore TORIC SECTIONS.

If $a < b$, the curve has AREA

$$A = \tfrac{1}{2} r^2\,d\theta = 2(\tfrac{1}{2})\int_{-\pi/4}^{\pi/4} r^2\,d\theta = a^2 + b^2 E\left(\frac{a^4}{b^4}\right), \quad (6)$$

where the integral has been done over half the curve and then multiplied by two and $E(x)$ is the complete ELLIPTIC INTEGRAL OF THE SECOND KIND. If $a = b$, the curve becomes

$$r^2 = a^2\left[\cos(2\theta) + \sqrt{1 - \sin^2\theta}\right] = 2a^2\cos(2\theta), \quad (7)$$

which is a LEMNISCATE having AREA

$$A = 2a^2 \quad (8)$$

(two loops of a curve $\sqrt{2}$ the linear scale of the usual lemniscate $r^2 = a^2\cos(2\theta)$, which has area $A = a^2/2$ for each loop). If $a > b$, the curve becomes two disjoint ovals with equations

$$r = \pm a\sqrt{\cos(2\theta) \pm \sqrt{\left(\frac{b}{a}\right)^2 - \sin^2(2\theta)}}, \quad (9)$$

where $\theta \in [-\theta_0, \theta_0]$ and

$$\theta_0 \equiv \tfrac{1}{2}\sin^{-1}\left[\left(\frac{b}{a}\right)^2\right]. \quad (10)$$

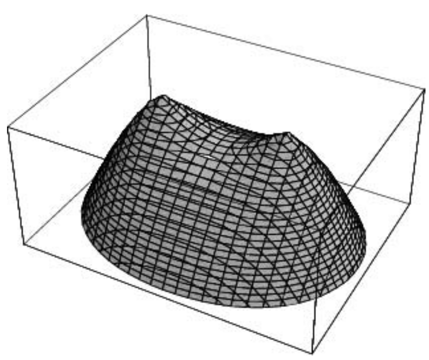
Cassini Surface

The QUARTIC SURFACE obtained by replacing the constant b in the equation of the CASSINI OVALS with $b = z$, obtaining



$$[(x-a)^2 + y^2][(x+a)^2 + y^2] = z^4. \tag{1}$$

As can be seen by letting $y = 0$ to obtain

$$(x^2 - a^2)^2 = z^4 \tag{2}$$

$$x^2 + z^2 = a^2, \tag{3}$$

the intersection of the surface with the $y = 0$ PLANE is a CIRCLE of RADIUS a.

Let a TORUS of tube radius a be cut by a plane perpendicular to the plane of the torus's centroid. Call the distance of this plane from the center of the torus hole r, let $a = r$, and consider the intersection of this plane with the torus as r is varied. The resulting curves are CASSINI OVALS, and the surface having these curves as CROSS SECTIONS is the Cassini surface

$$(x + 2 + z^2 + c^2) - 4c^2x^2 = 4c^2r^2,$$

which has a scaled r^2 on the right side instead of z^4 (Gosper).

Cassini's Identity

For F_n the nth FIBONACCI NUMBER,

$$F_{n-1}F_{n+1} - F_n^2 = (-1)^n.$$

This identity was also discovered by Simson (Coxeter and Greitzer 1967, p. 41; Coxeter 1969, pp. 165–168). It is a special case of CATALAN'S IDENTITY with $r = 1$.

Casting Out Nines

An elementary check of a MULTIPLICATION which makes use of the CONGRUENCE $10^n \equiv 1 \pmod 9$ for $n \geq 2$. From this CONGRUENCE, a MULTIPLICATION $ab = c$ must give

$$a \equiv \sum a_i = a^*$$

$$b \equiv \sum b_i = b^*$$

$$c \equiv \sum c_i = c^*,$$

so $ab \equiv a^*b^*$ must be $\equiv c^*$ (mod 9). Casting out nines was transmitted to Europe by the Arabs, but was probably an Indian invention and is therefore sometimes also called "the Hindu check." The procedure was described by Fibonacci in his *Liber Abaci* (Wells 1986, p. 74).

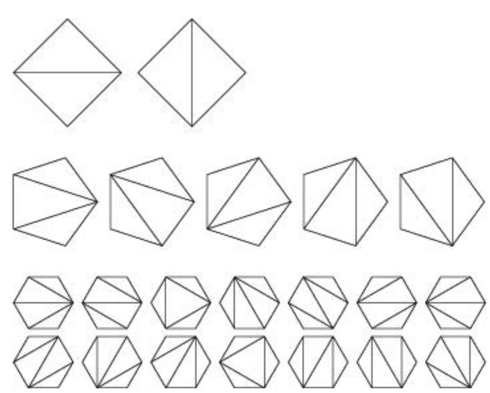
Catalan

CATALAN'S CONSTANT

Catalan Integrals

Special cases of general FORMULAS due to Bessel.



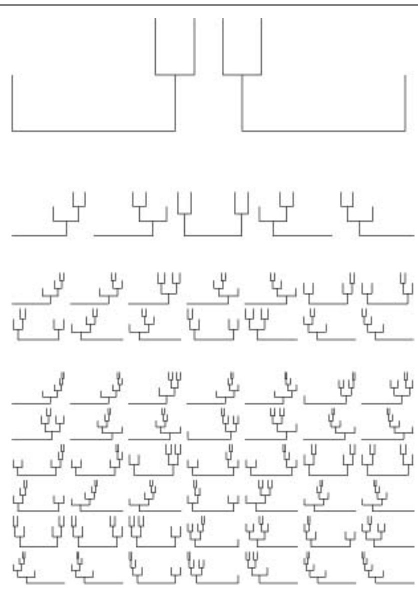
$$J_0(\sqrt{z^2-y^2}) = \frac{1}{\pi}\int_0^\pi e^{y\cos\theta}\cos(z\sin\theta)\,d\theta,$$

where $J_0(z)$ is a BESSEL FUNCTION OF THE FIRST KIND. Now, let $z \equiv 1-z'$ and $y \equiv 1+z'$. Then

$$J_0(2i\sqrt{z}) = \frac{1}{\pi}\int_0^\pi e^{(1+z)\cos\theta}\cos[(1-z)\sin\theta]\,d\theta.$$

See also BESSEL FUNCTION OF THE FIRST KIND

Catalan Number



The Catalan numbers are an INTEGER SEQUENCE $\{C_n\}$ which appears in TREE enumeration problems of the type, "In how many ways can a regular n-gon be

divided into $n-2$ TRIANGLES if different orientations are counted separately?" (EULER'S POLYGON DIVISION PROBLEM). The solution is the Catalan number C_{n-2} (Dörrie 1965, Honsberger 1973), as graphically illustrated above (Dickau). The first few Catalan numbers for $n = 1, 2, \ldots$ are 1, 2, 5, 14, 42, 132, 429, 1430, 4862, 16796, ... (Sloane's A000108).

The only ODD Catalan numbers are those OF THE FORM C_{2^k-1}, and the last DIGIT is five for $k = 9$ to 15. The only PRIME Catalan numbers for $n \le 2^{15}-1$ are $C_2 = 2$ and $C_3 = 5$.

The Catalan numbers turn up in many other related types of problems. C_{n-1} can also be defined as the number of $(-1, 1)$-sequences $\{s_1, s_2, \ldots, s_n\}$ such that $\Sigma_{i=1}^{2n} s_j = 0$ and $\Sigma_{j=1}^{i} s_j \ge 0$ for $i \le 2n-1$ (Mays and Wojciechowski 2000). The following table gives the first few such sequences.

n	lists
1	$\{1, -1\}$
2	$\{1, 1, -1, -1\}$
3	$\{1, 1, -1, 1, -1, -1\}$, $\{1, 1, 1, -1, -1, -1\}$
4	$\{1, 1, -1, 1, -1, 1, -1, -1\}$,
	$\{1, 1, -1, 1, 1, -1, -1, -1\}$,
	$\{1, 1, 1, -1, -1, 1, -1, -1\}$,
	$\{1, 1, 1, -1, 1, -1, -1, -1\}$,
	$\{1, 1, 1, 1, -1, -1, -1, -1\}$

The Catalan number C_{n-1} also gives the number of BINARY BRACKETINGS of n letters (CATALAN'S PROBLEM), the solution to the BALLOT PROBLEM, the number of trivalent PLANTED PLANAR TREES (Dickau; illustrated above), the number of states possible in an n-FLEXAGON, the number of different diagonals possible in a FRIEZE PATTERN with $n+1$ rows, the number of ways of forming an n-fold exponential, the number of rooted planar binary trees with n internal nodes, the number of rooted plane bushes with n EDGES, the number of extended BINARY TREES with n internal nodes, the number of mountains which can be drawn with n upstrokes and n downstrokes, the number of noncrossing handshakes possible across a round table between n pairs of people (Conway and Guy 1996), and the number of SEQUENCES with NONNEGATIVE PARTIAL SUMS which can be formed from n 1s and n -1s (Bailey 1996, Brualdi 1992)!

An explicit formula for C_n is given by

$$C_n \equiv \frac{1}{n+1}\binom{2n}{n} = \frac{1}{n+1}\frac{(2n)!}{n!^2} = \frac{(2n)!}{(n+1)!n!}, \tag{1}$$

where $\binom{2n}{n}$ denotes a BINOMIAL COEFFICIENT and $n!$ is the usual FACTORIAL. A RECURRENCE RELATION for C_n is obtained from

$$\begin{aligned}\frac{C_{n+1}}{C_n} &= \frac{(2n+2)!}{(n+2)[(n+1)!]^2}\frac{(n+1)(n!)^2}{(2n)!}\\ &= \frac{(2n+2)(2n+1)(n+1)}{(n+2)(n+1)^2} = \frac{2(2n+1)(n+1)^2}{(n+1)^2(n+2)}\\ &= \frac{2(2n+1)}{n+2},\end{aligned} \tag{2}$$

so

$$C_{n+1} = \frac{2(2n+1)}{n+2}C_n. \tag{3}$$

Other forms include

$$C_n = \frac{2\cdot 6\cdot 10\cdots(4n-2)}{(n+1)!} \tag{4}$$

$$= \frac{2^n(2n-1)!!}{(n+1)!} \tag{5}$$

$$= \frac{(2n)!}{n!(n+1)!}. \tag{6}$$

SEGNER'S RECURRENCE FORMULA, given by Segner in 1758, gives the solution to EULER'S POLYGON DIVISION PROBLEM

$$E_n = E_2E_{n-1} + E_3E_{n-2} + \ldots + E_{n-1}E_2. \tag{7}$$

With $E_1 = E_2 = 1$, the above RECURRENCE RELATION gives the Catalan number $C_{n-2} = E_n$.

The GENERATING FUNCTION for the Catalan numbers is given by

$$\frac{1-\sqrt{1-4x}}{2x} = \sum_{n=0}^{\infty} C_n x^n = 1 + x + 2x^2 + 5x^3 + \ldots. \quad (8)$$

The asymptotic form for the Catalan numbers is

$$C_k \sim \frac{4^k}{\sqrt{\pi} k^{3/2}} \quad (9)$$

(Vardi 1991, Graham *et al.* 1994).

A generalization of the Catalan numbers is defined by

$$_p d_k = \frac{1}{k}\binom{pk}{k-1} = \frac{1}{(p-1)k+1}\binom{pk}{k} \quad (10)$$

for $k \geq 1$ (Klarner 1970, Hilton and Pederson 1991). The usual Catalan numbers $C_k = {}_2 d_k$ are a special case with $p = 2$. $_p d_k$ gives the number of p-ary TREES with k source-nodes, the number of ways of associating k applications of a given p-ary OPERATOR, the number of ways of dividing a convex POLYGON into k disjoint $(p+1)$-gons with nonintersecting DIAGONALS, and the number of P-GOOD PATHS from $(0, -1)$ to $(k, (p-1)k-1)$ (Hilton and Pederson 1991).

A further generalization is obtained as follows. Let p be an INTEGER > 1, let $P_k = (k, (p-1)k-1)$ with $k \geq 0$, and $q \leq p-1$. Then define $_p d_{q0} = 1$ and let $_p d_{qk}$ be the number of$P$-GOOD PATHS from $(1, q-1)$ to P_k (Hilton and Pederson 1991). Formulas for $_p d_{qi}$ include the generalized JONAH FORMULA

$$\binom{n-q}{k-1} = \sum_{i=1}^{k} {}_p d_{qi} \binom{n-pi}{k-i} \quad (11)$$

and the explicit formula

$$_p d_{qk} = \frac{p-q}{pk-q}\binom{pk-q}{k-1}. \quad (12)$$

A RECURRENCE RELATION is given by

$$_p d_{qk} = \sum_{i,j} {}_p d_{p-r,\, i}\, {}_p d_{q+r,\, j} \quad (13)$$

where $i, j, r \geq 1$, $k \geq 1$, $q < p - r$, and $i + j = k + 1$ (Hilton and Pederson 1991).

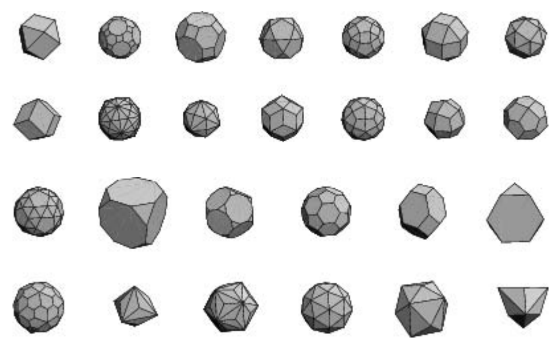
Catalan Solid

The DUAL POLYHEDRA of the ARCHIMEDEAN SOLIDS, given in the following table. They are known as Catalan solids in honor of the French mathematician who first published them in 1862 (Wenninger 1983, p. 1).



n	ARCHIMEDEAN SOLID	DUAL
1	CUBOCTAHEDRON	RHOMBIC DODECAHEDRON
2	GREAT RHOMBICOSIDODECAHEDRON	DISDYAKIS TRIACONTAHEDRON
3	GREAT RHOMBICUBOCTAHEDRON	DISDYAKIS DODECAHEDRON
4	ICOSIDODECAHEDRON	RHOMBIC TRIACONTAHEDRON
5	RHOMBICOSIDODECAHEDRON	DELTOIDAL HEXECONTAHEDRON
6	SMALL RHOMBICUBOCTAHEDRON	DELTOIDAL ICOSITETRAHEDRON
7	SNUB CUBE (laevo)	PENTAGONAL ICOSITETRAHEDRON (dextro)
8	SNUB DODECAHEDRON (laevo)	PENTAGONAL HEXECONTAHEDRON (dextro)
9	TRUNCATED CUBE	SMALL TRIAKIS OCTAHEDRON
10	TRUNCATED DODECAHEDRON	TRIAKIS ICOSAHEDRON
11	TRUNCATED ICOSAHEDRON	PENTAKIS DODECAHEDRON
12	TRUNCATED OCTAHEDRON	TETRAKIS HEXAHEDRON
13	TRUNCATED TETRAHEDRON	TRIAKIS TETRAHEDRON

Here are the ARCHIMEDEAN DUALS (Pearce 1978, Holden 1991) displayed in the order listed above (left to right, then continuing to the next row).

Here are the Archimedean solids paired with the corresponding Catalan solids.

Catalan's Aliquot Sequence Conjecture

The conjecture proposed by Catalan in 1888 and extended by E. Dickson that each ALIQUOT SEQUENCE ends in a PRIME, a PERFECT NUMBER, or a set of SOCIABLE NUMBERS. The conjecture remains open to this day.

See also ALIQUOT SEQUENCE, SOCIABLE NUMBERS

References

Creyaufmüller, W. "Aliquot Sequences." http://home.t-online.de/home/Wolfgang.Creyaufmueller/aliquote.htm.

Catalan's Conjecture

8 and 9 (2^3 and 3^2) are the only consecutive POWERS (excluding 0 and 1), i.e., the only solution to CATALAN'S DIOPHANTINE PROBLEM. Solutions to this problem (CATALAN'S DIOPHANTINE PROBLEM) are equivalent to solving the simultaneous DIOPHANTINE EQUATIONS

$$X^2 - Y^3 = 1$$
$$X^3 - Y^2 = 1.$$

This CONJECTURE has not yet been proved or refuted, although it has been shown to be decidable in a FINITE (but more than astronomical) number of steps. In particular, if n and $n+1$ are POWERS, then $n <$ exp exp exp exp 730 (Guy 1994, p. 155), which follows from R. Tijdeman's proof that there can be only a FINITE number of exceptions should the CONJECTURE not hold.

Hyyro and Makowski proved that there do not exist three consecutive POWERS (Ribenboim 1996), and it is also known that 8 and 9 are the only consecutive CUBIC and SQUARE NUMBERS (in either order).

Catalan's Constant

A constant which appears in estimates of combinatorial functions. It is usually denoted K, $\beta(2)$, or G. It is not known if K is IRRATIONAL. Numerically,

$$K = 0.915965594177\ldots \quad (1)$$

(Sloane's A006752). The CONTINUED FRACTION for K is [0, 1, 10, 1, 8, 1, 88, 4, 1, 1, ...] (Sloane's A014538). K can be given analytically by the following expressions,

$$K \equiv \beta(2) \quad (2)$$

$$= -i\chi_2(i) \quad (3)$$

$$= \sum_{k=0}^{\infty} \frac{(-1)^k}{(2k+1)^2} = \frac{1}{1^2} - \frac{1}{3^2} + \frac{1}{5^2} + \ldots \quad (4)$$

$$= 1 + \sum_{n=1}^{\infty} \frac{1}{(4n+1)^2} - \frac{1}{9} - \sum_{n=1}^{\infty} \frac{1}{(4n+3)^2} \quad (5)$$

$$= \int_0^1 \frac{\tan^{-1} x\, dx}{x} \quad (6)$$

$$= -\int_0^1 \frac{\ln x\, dx}{1+x^2}, \quad (7)$$

where $\beta(z)$ is the DIRICHLET BETA FUNCTION and $\chi_\nu(z)$ is LEGENDRE'S CHI-FUNCTION. In terms of the POLYGAMMA FUNCTION $\Psi_1(x)$,

$$K = \tfrac{1}{16}\Psi_1(\tfrac{1}{4}) - \tfrac{1}{16}\Psi_1(\tfrac{3}{4}) \quad (8)$$

$$= \tfrac{1}{80}\Psi_1(\tfrac{5}{12}) + \tfrac{1}{80}\Psi_1(\tfrac{1}{12}) - \tfrac{1}{10}\pi^2 \quad (9)$$

$$= \tfrac{1}{32}\Psi_1(\tfrac{1}{8}) - \tfrac{1}{32}\Psi_1(\tfrac{3}{8}) - \tfrac{1}{16}\sqrt{2}. \quad (10)$$

Applying CONVERGENCE IMPROVEMENT to (4) gives

$$K = \frac{1}{16}\sum_{m=1}^{\infty}(m+1)\frac{3^m-1}{4^m}\zeta(m+2), \quad (11)$$

where $\zeta(z)$ is the RIEMANN ZETA FUNCTION and the identity

$$\frac{1}{(1-3z)^2} - \frac{1}{(1-z)^2} = \sum_{m=1}^{\infty}(m+1)\frac{3^m-1}{4^m}z^m \quad (12)$$

has been used (Flajolet and Vardi 1996). The Flajolet and Vardi algorithm also gives

$$K = \frac{1}{\sqrt{2}}\prod_{k=1}^{\infty}\left[\left(1-\frac{1}{2^{2^k}}\right)\frac{\zeta(2^k)}{\beta(2^k)}\right]^{1/(2^{k+1})}, \quad (13)$$

where $\beta(z)$ is the DIRICHLET BETA FUNCTION. Glaisher (1913) gave

$$K = 1 - \sum_{n=1}^{\infty}\frac{n\zeta(2n+1)}{16^n} \quad (14)$$

(Vardi 1991, p. 159). W. Gosper used the related FORMULA

$$K = \frac{1}{\sqrt{2}}\left[\frac{1}{\Psi(2)-1}\right]^{2^{1/2}}\prod_{k=2}^{\infty}\left[\frac{1}{-\Psi(2^k)-1}\right]^{1/(2^{k+1})}, \quad (15)$$

where

$$\Psi(m) = \frac{m\psi_{m-1}(\frac{1}{4})}{\pi^m(2^m-1)4^{m-1}B_m}, \quad (16)$$

where B_n is a BERNOULLI NUMBER and $\psi(x)$ is a POLYGAMMA FUNCTION (Finch). The Catalan constant may also be defined by

$$K \equiv \tfrac{1}{2}\int_0^1 K(k)\,dk, \quad (17)$$

where $K(k)$ (not to be confused with Catalan's constant itself, denoted K) is a complete ELLIPTIC INTEGRAL OF THE FIRST KIND.

$$K = \frac{\pi \ln 2}{8} + \sum_{i=1}^{\infty} \frac{a_i}{2^{\lfloor (i+1)/2 \rfloor} i^2}, \quad (18)$$

where

$$\{a_i\} = \{\overline{1,\ 1,\ 1,\ 0,\ -1,\ -1,\ -1,\ 0}\} \quad (19)$$

is given by the periodic sequence obtained by appending copies of $\{1, 1, 1, 0, -1, -1, -1, 0\}$ (in other words, $a_i \equiv a_{[i-1 \pmod 8]+1}$ for $i > 8$) and $\lfloor x \rfloor$ is the FLOOR FUNCTION (Nielsen 1909).

Catalan's Diophantine Problem

Find consecutive POWERS, i.e., solutions to

$$a^b - c^d = 1,$$

excluding 0 and 1. CATALAN'S CONJECTURE is that the only solution is $3^2 - 2^3 = 1$, so 8 and 9 (2^3 and 3^2) are the only consecutive POWERS (again excluding 0 and 1).

Catalan's Identity

$$F_n^2 - F_{n+r}F_{n-r} = (-1)^{n-r}F_r^2,$$

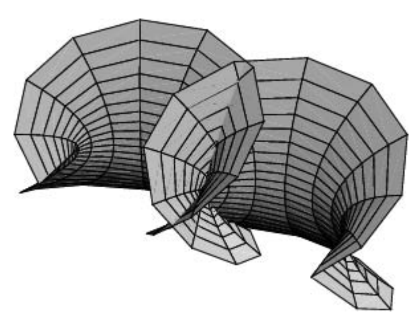
where F_n is a FIBONACCI NUMBER. Letting $r = 1$ gives CASSINI'S IDENTITY.

See also CASSINI'S IDENTITY, D'OCAGNE'S IDENTITY, FIBONACCI NUMBER

Catalan's Problem

The problem of finding the number of different ways in which a PRODUCT of n different ordered FACTORS can be calculated by pairs (i.e., the number of BINARY BRACKETINGS of n letters). For example, for the four FACTORS a, b, c, and d, there are five possibilities: $((ab)c)d$, $(a(bc))d$, $(ab)(cd)$, $a((bc)d)$, and $a(b(cd))$. The solution was given by Catalan in 1838 as

$$C'_n = \frac{(4n-6)!!!!}{n!} = \frac{2 \cdot 6 \cdot 10 \cdots (4n-6)}{n!},$$



where $n!!!!$ is a MULTIFACTORIAL and $n!$ is the usual FACTORIAL, which is equal to the CATALAN NUMBER $C_{n-1} = C'_n$.

Catalan's Surface

A MINIMAL SURFACE given by the PARAMETRIC EQUA-

TIONS

$$x(u, v) = u - \sin u \cosh v \quad (1)$$

$$y(u, v) = 1 - \cos u \cosh v \quad (2)$$

$$z(u, v) = 4 \sin(\tfrac{1}{2}u) \sinh(\tfrac{1}{2}v) \quad (3)$$

(Gray 1997), or

$$x(r, \phi) = a \sin(2\phi) - 2a\phi + \tfrac{1}{2}av^2 \cos(2\phi) \quad (4)$$

$$y(r, \phi) = -a \cos(2\phi) - \tfrac{1}{2}av^2 \cos(2\phi) \quad (5)$$

$$z(r, \phi) = 2av \sin \phi, \quad (6)$$

where

$$v = -r + \frac{1}{r} \quad (7)$$

(do Carmo 1986).

Catalan's Triangle

A triangle of numbers with entries given by

$$c_{nm} = \frac{(n+m)!(n-m+1)}{m!(n+1)!}$$

for $0 \leq m \leq n$, where each element is equal to the one above plus the one to the left. Furthermore, the sum of each row is equal to the last element of the next row and also equal to the CATALAN NUMBER C_n.

Catastrophe

For any system that seeks to minimize a function, only seven different local forms of CATASTROPHE "typically" occur for four or fewer variables:

1. FOLD CATASTROPHE,
2. CUSP CATASTROPHE,
3. SWALLOWTAIL CATASTROPHE,
4. BUTTERFLY CATASTROPHE,
5. ELLIPTIC UMBILIC CATASTROPHE,
6. HYPERBOLIC UMBILIC CATASTROPHE, and
7. PARABOLIC UMBILIC CATASTROPHE.

More specifically, for any system with fewer than five control factors and fewer than three behavior axes, these are the only seven catastrophes possible. The following tables gives the possible catastrophes as a function of control factors and behavior axes (Goetz).

Control Factors	1 Behavior Axis	2 Behavior Axes
1	FOLD	
2	CUSP	
3	SWALLOWTAIL	HYPERBOLIC UMBILIC, ELLIPTIC UMBILIC
4	BUTTERFLY	PARABOLIC UMBILIC

The following table gives prototypical examples for equations showing each type of catastrophe.

equation	catastrophe
x^3+ux	FOLD CATASTROPHE
x^4+ux^2+vx	CUSP CATASTROPHE, Riemann-Hugoniot catastrophe
$x^5+ux^3+vx^2+wx$	SWALLOWTAIL CATASTROPHE
$x^3+y^3+uxy+vx+wy$	HYPERBOLIC UMBILIC CATASTROPHE
$x^3-xy^2+u(x^2+y^2)+vx+wy$	ELLIPTIC UMBILIC CATASTROPHE
$x^6+ux^4+vx^3+wx^2+tx$	BUTTERFLY CATASTROPHE
$x^2y+y^4+ux^2+vy^2+wx+ty$	PARABOLIC UMBILIC CATASTROPHE

See also BUTTERFLY CATASTROPHE, CATASTROPHE THEORY, CUSP CATASTROPHE, ELLIPTIC UMBILIC CATASTROPHE, FOLD CATASTROPHE, HYPERBOLIC UMBILIC CATASTROPHE, PARABOLIC UMBILIC CATASTROPHE, SWALLOWTAIL CATASTROPHE

Catastrophe Theory

Catastrophe theory studies how the qualitative nature of equation solutions depends on the parameters that appear in the equations. Subspecializations include bifurcation theory, nonequilibrium thermodynamics, singularity theory, synergetics, and topological dynamics. For any system that seeks to minimize a function, only seven different local forms of CATASTROPHE "typically" occur for four or fewer variables.

See also CATASTROPHE

Categorical Game

A GAME in which no DRAW is possible. All CATEGORICAL GAMES are unfair (Steinhaus 1983, p. 16).

See also DRAW, GAME

References

Steinhaus, H. *Mathematical Snapshots, 3rd ed.* New York: Dover, p. 16 1999.

Categorical Variable

A variable which belongs to exactly one of a finite number of CATEGORIES.

See also CATEGORY

Category

A category consists of two things: a collection of OBJECTS and, for each pair of OBJECTS, a collection of MORPHISMS (sometimes called "arrows") from one to another.

In most concrete categories over sets, an OBJECT is some mathematical structure (e.g., a GROUP, VECTOR SPACE, or DIFFERENTIABLE MANIFOLD) and a MORPHISM is a MAP between two OBJECTS. The MORPHISMS are then required to satisfy some fairly natural conditions; for instance, the IDENTITY MAP between any object and itself is always a MORPHISM, and the composition of two MORPHISMS (if defined) is always a MORPHISM.

One usually requires the MORPHISMS to preserve the mathematical structure of the objects. So if the objects are all groups, a good choice for a MORPHISM would be a group HOMOMORPHISM. Similarly, for vector spaces, one would choose linear maps, and for differentiable manifolds, one would choose differentiable maps.

In the category of TOPOLOGICAL SPACES, homomorphisms are usually continuous maps between topological spaces. However, there are also other category structures having TOPOLOGICAL SPACES as objects, but they are not nearly as important as the "standard" category of TOPOLOGICAL SPACES and continuous maps.

Category Theory

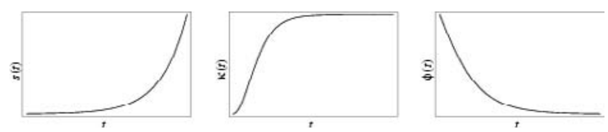
The branch of mathematics which formalizes a number of algebraic properties of collections of transformations between mathematical objects (such as binary relations, groups, sets, topological spaces, etc.) of the same type, subject to the constraint that the collections contain the identity mapping and are closed with respect to compositions of mappings. The objects studied in category theory are called CATEGORIES.

See also CATEGORY

Catenary

The curve a hanging flexible wire or chain assumes when supported at its ends and acted upon by a uniform gravitational force. The word catenary is derived from the Latin word for "chain." In 1669, Jungius disproved Galileo's claim that the curve of a chain hanging under gravity would be a PARABOLA (MacTutor Archive). The curve is also called the alysoid and chainette. The equation was obtained by Leibniz, Huygens, and Johann Bernoulli in 1691 in response to a challenge by Jakob Bernoulli.

Huygens was the first to use the term catenary in a letter to Leibniz in 1690, and David Gregory wrote a treatise on the catenary in 1690 (MacTutor Archive). If you roll a PARABOLA along a straight line, its FOCUS traces out a catenary. As proved by Euler in 1744, the catenary is also the curve which, when rotated, gives the surface of minimum SURFACE AREA (the CATENOID) for the given bounding CIRCLE.



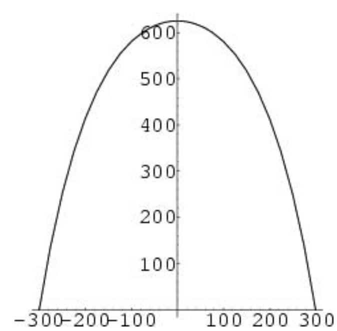
The PARAMETRIC EQUATIONS for the catenary are given by

$$x(t) = t \tag{1}$$

$$y(t) = \tfrac{1}{2} a(e^{t/a} + e^{-t/a}) = a \cosh\left(\frac{t}{a}\right), \tag{2}$$

where $t = 0$ corresponds to the vertex, and the CESÀRO EQUATION is

$$(s^2 + a^2)\kappa = -a. \tag{3}$$



The ARC LENGTH, CURVATURE, and TANGENTIAL ANGLE are

$$s(t) = a \sinh\left(\frac{t}{a}\right), \tag{4}$$

$$\kappa(t) = -\frac{1}{a} \operatorname{sech}^2\left(\frac{t}{a}\right), \tag{5}$$

$$\phi(t) = -2 \tan^{-1}\left[\tanh\left(\frac{t}{2a}\right)\right]. \tag{6}$$

The slope is proportional to the ARC LENGTH as measured from the center of symmetry.

The St. Louis Arch closely approximates an inverted catenary, but it has a finite thickness and varying cross sectional area (thicker at the base; thinner at the apex). The centroid has half-length of $L = 299.2239$ feet at the base, height of 625.0925 feet, top cross sectional area 125.1406 square feet, and bottom cross sectional area 1262.6651 square feet.

The catenary also gives the shape of the road (ROULETTE) over which a regular polygonal "wheel" can travel smoothly. For a regular n-gon, the Cartesian equation of the corresponding catenary is

$$y = -A \cosh\left(\frac{x}{A}\right), \tag{7}$$

where

$$A \equiv R \cos\left(\frac{\pi}{n}\right). \quad (8)$$

Catenary Evolute

$$x = a[x - \tfrac{1}{2}\sinh(2t)]$$

$$y = 2a \cosh t.$$

Catenary Involute

The parametric equation for a catenary is

$$\mathbf{r}(t) = a\begin{bmatrix} t \\ \cosh t \end{bmatrix}, \quad (1)$$

so

$$\frac{d\mathbf{r}}{dt} = a\begin{bmatrix} 1 \\ \sinh t \end{bmatrix} \quad (2)$$

$$\left|\frac{d\mathbf{r}}{dt}\right| = a\sqrt{1+\sinh^2 t} = a \cosh t \quad (3)$$

and

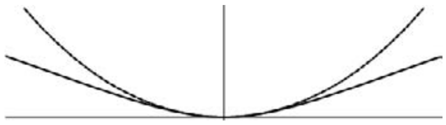
$$\hat{\mathbf{T}} = \frac{\frac{d\mathbf{r}}{dt}}{\left|\frac{d\mathbf{r}}{dt}\right|} = \begin{bmatrix} \operatorname{sech} t \\ \tanh t \end{bmatrix} \quad (4)$$

$$ds^2 = |d\mathbf{r}^2| = a^2(1+\sinh^2 t)\, dt^2 = a^2 \cosh^2 dt^2 \quad (5)$$

$$\frac{ds}{dt} = a \cosh t. \quad (6)$$

Therefore,

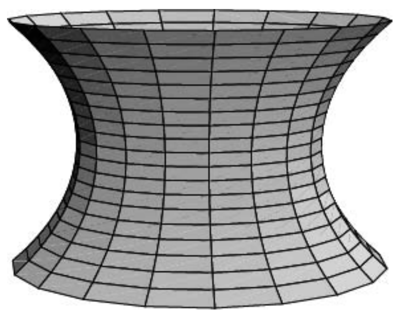
$$s = a\int \cosh t\, dt = a \sinh t \quad (7)$$



and the equation of the involute is

$$x = a(t - \tanh t) \quad (8)$$

$$y = a \operatorname{sech} t. \quad (9)$$



This curve is called a tractrix.

Catenary Radial Curve

The KAMPYLE OF EUDOXUS.

Catenoid

A CATENARY of REVOLUTION. The catenoid and PLANE are the only SURFACES OF REVOLUTION which are also MINIMAL SURFACES. The catenoid can be given by the PARAMETRIC EQUATIONS

$$x = c \cosh\left(\frac{v}{c}\right) \cos u \tag{1}$$

$$y = c \cosh\left(\frac{v}{c}\right) \sin u \tag{2}$$

$$z = v, \tag{3}$$

where $u \in [0, 2\pi)$. The differentials are

$$dx = \sinh\left(\frac{v}{c}\right) \cos u \, dv - \cosh\left(\frac{v}{c}\right) \sin u \, du \tag{4}$$

$$dy = \sinh\left(\frac{v}{c}\right) \sin u \, dv + \cosh\left(\frac{v}{c}\right) \cos u \, du \tag{5}$$

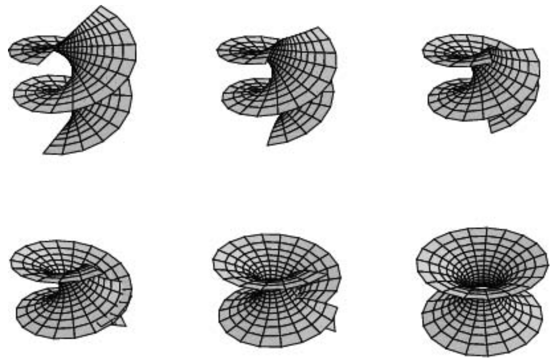
$$dz = du, \tag{6}$$

so the LINE ELEMENT is

$$\begin{aligned} ds^2 &= dx^2 + dy^2 + dz^2 \\ &= \left[\sinh^2\left(\frac{v}{c}\right) + 1\right] dv^2 + \cosh^2\left(\frac{v}{c}\right) du^2 \\ &= \cosh^2\left(\frac{v}{c}\right) dv^2 + \cosh^2\left(\frac{v}{c}\right) du^2. \end{aligned} \tag{7}$$

The PRINCIPAL CURVATURES are

$$\kappa_1 = -\frac{1}{c} \operatorname{sech}^2\left(\frac{v}{c}\right) \tag{8}$$



$$\kappa_2 = \frac{1}{c} \operatorname{sech}^2\left(\frac{v}{c}\right). \tag{9}$$

The MEAN CURVATURE of the catenoid is

$$H = 0 \tag{10}$$

and the GAUSSIAN CURVATURE is

$$K = -\frac{1}{c^2} \operatorname{sech}^4\left(\frac{v}{c}\right). \tag{11}$$

The HELICOID can be continuously deformed into a catenoid with $c = 1$ by the transformation

$$x(u, v) = \cos\alpha \sinh v \sin u + \sin\alpha \cosh v \cos u \tag{12}$$

$$y(u, v) = -\cos\alpha \sinh v \cos u + \sin\alpha \cosh v \sin u \tag{13}$$

$$z(u, v) = u \cos\alpha + v \sin\alpha, \tag{14}$$

where $\alpha = 0$ corresponds to a HELICOID and $\alpha = \pi/2$ to a catenoid.

Caterpillar Graph

A TREE with every NODE on a central stalk or only one EDGE away from the stalk. A tree is a caterpillar graph IFF all nodes of degree ≥ 3 are surrounded by at most two nodes of degree two or greater. The number of caterpillar graphs on $n = 1, 2, ...$ nodes are 1, 1, 1, 2, 3, 6, 10, 20, 36, 72, 136, ... (Sloane's A005418), giving the number of noncaterpillar graphs on $n = 7, 8, ...$ as 1, 3, 11, 34, 99, ... (Sloane's A052471). The noncaterpillar graphs on $n \leq 9$ nodes are illustrated above.

Cattle Problem of Archimedes

ARCHIMEDES' CATTLE PROBLEM

Cauchy Binomial Theorem

$$\prod_{k=1}^{n}(1+yq^k) = \sum_{m=0}^{n} y^m q^{m(m+1)/2} \begin{bmatrix} n \\ m \end{bmatrix}_q = \sum_{m=0}^{n} y^m q^{m(m+1)/2} \frac{(q)_n}{(q)_m (q)_{n-m}},$$

where $[n\mathbf{r}m]_q$ is a Q-BINOMIAL COEFFICIENT.

See also Q-BINOMIAL COEFFICIENT, Q-BINOMIAL THEOREM

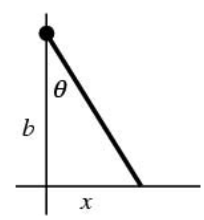
Cauchy Boundary Conditions

BOUNDARY CONDITIONS of a PARTIAL DIFFERENTIAL EQUATION which are a weighted AVERAGE of DIRICHLET BOUNDARY CONDITIONS (which specify the value of the function on a surface) and NEUMANN BOUNDARY CONDITIONS (which specify the normal derivative of the function on a surface).

See also BOUNDARY CONDITIONS, CAUCHY PROBLEM, DIRICHLET BOUNDARY CONDITIONS, NEUMANN BOUNDARY CONDITIONS

References

Morse, P. M. and Feshbach, H. *Methods of Theoretical Physics, Part I.* New York: McGraw-Hill, pp. 678–679, 1953.



Cauchy Condition

UNIFORMLY CAUCHY

Cauchy Criterion

A NECESSARY and SUFFICIENT condition for a SEQUENCE S_i to CONVERGE. The Cauchy criterion is satisfied when, for all $\epsilon > 0$, there is a fixed number N such that $|S_j - S_i| < \epsilon$ for all $i, j > N$.

Cauchy Distribution

The Cauchy distribution, also called the LORENTZIAN DISTRIBUTION, is a continuous distribution describing resonance behavior. It also describes the distribution of horizontal distances at which a LINE SEGMENT tilted at a random ANGLE cuts the X-AXIS. Let θ represent the ANGLE that a line, with fixed point of rotation, makes with the vertical axis, as shown above. Then

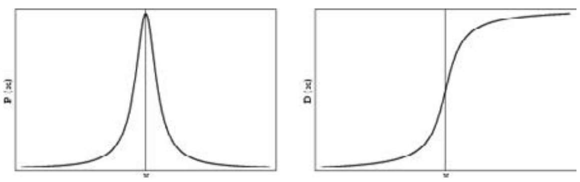
$$\tan\theta = \frac{x}{b} \tag{1}$$

$$\theta = \tan^{-1}\left(\frac{x}{b}\right) \tag{2}$$

$$d\theta = -\frac{1}{1+\frac{x^2}{b^2}}\frac{dx}{b} = -\frac{b\,dx}{b^2+x^2}, \tag{3}$$

so the distribution of ANGLE θ is given by

$$\frac{d\theta}{\pi} = -\frac{1}{\pi}\frac{b\,dx}{b^2+x^2}. \tag{4}$$



This is normalized over all angles, since

$$\int_{-\pi/2}^{\pi/2}\frac{d\theta}{\pi} = 1 \tag{5}$$

and

$$-\int_{-\infty}^{\infty} \frac{1}{\pi} \frac{b\,dx}{b^2+x^2} = \frac{1}{\pi}\left[\tan^{-1}\left(\frac{b}{x}\right)\right]_{-\infty}^{\infty}$$

$$= \frac{1}{\pi}[\tfrac{1}{2}\pi - (-\tfrac{1}{2}\pi)] = 1. \qquad (6)$$

The general Cauchy distribution and its cumulative distribution can be written as

$$P(x) = \frac{1}{\pi} \frac{\frac{1}{2}\Gamma}{(x-m)^2 + (\frac{1}{2}\Gamma)^2} \qquad (7)$$

$$D(x) = \frac{1}{2} + \frac{1}{\pi}\tan^{-1}\left(\frac{x-m}{b}\right), \qquad (8)$$

where Γ is the FULL WIDTH AT HALF MAXIMUM ($\Gamma = 2b$ in the above example) and m is the MEDIAN ($m = 0$ in the above example). The CHARACTERISTIC FUNCTION is

$$\phi(t) = \frac{1}{\pi}\int_{-\infty}^{\infty} e^{itx} \frac{\frac{1}{2}\Gamma}{(\frac{1}{2}\Gamma)^2 + (x-m)^2}\,dx = e^{imt - \Gamma|t|/2}. \qquad (9)$$

The MOMENTS μ_n of the distribution are undefined since the integrals

$$\mu_n = \int_{-\infty}^{\infty} \frac{\Gamma}{2\pi} \frac{x^n}{(x-m)^2 + (\frac{1}{2}\Gamma)^2} \qquad (10)$$

diverge for $n \geq 1$.
If X and Y are variates with a NORMAL DISTRIBUTION, then $Z \equiv X/Y$ has a Cauchy distribution with MEDIAN $m = 0$ and full width

$$\Gamma = \frac{2\sigma_y}{\sigma_x}. \qquad (11)$$

The sum of n variates each from a Cauchy distribution has itself a Cauchy distribution, as can be seen from

$$P_n(x) = \mathcal{F}^{-1}\{[\phi(t)]^n\} = \frac{(\frac{1}{2}n\Gamma)}{\pi[(\frac{1}{2}n\Gamma)^2 + (x-nm)^2]}, \qquad (12)$$

where $\phi(t)$ is the CHARACTERISTIC FUNCTION and $\mathcal{F}^{-1}|f|$ is the inverse FOURIER TRANSFORM, taken with parameters $a = b = 1$.

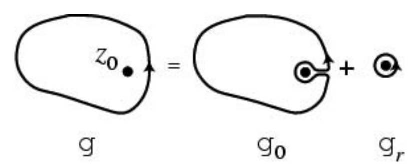
Cauchy Equation



EULER EQUATION

Cauchy Functional Equation

The fifth of HILBERT'S PROBLEMS is a generalization of this equation.

See also HILBERT'S PROBLEMS

Cauchy Integral Formula

Given a CONTOUR INTEGRAL OF THE FORM

$$\oint_\gamma \frac{f(z)\,dz}{z-z_0}, \qquad (1)$$

define a path γ_r as an infinitesimal clockwise CIRCLE around the point z_0 (the dot in the above illustration), and define the path γ_0 as an arbitrary loop with a cut line (on which the forward and reverse contributions cancel each other out) so as to go around z_0.
The total path is then

$$\gamma = \gamma_0 + \gamma_r, \qquad (2)$$

so

$$\oint_\gamma \frac{f(z)\,dz}{z-z_0} = \oint_{\gamma_0} \frac{f(z)\,dz}{z-z_0} + \oint_{\gamma_r} \frac{f(z)\,dz}{z-z_0}. \qquad (3)$$

From the CAUCHY INTEGRAL THEOREM, the CONTOUR INTEGRAL along any path not enclosing a POLE is 0. Therefore, the first term in the above equation is 0 since γ_0 does not enclose the POLE, and we are left with

$$\oint_\gamma \frac{f(z)\,dz}{z-z_0} = \oint_{\gamma_r} \frac{f(z)\,dz}{z-z_0}. \qquad (4)$$

Now, let $z \equiv z_0 + re^{i\theta}$, so $dz = ire^{i\theta}\,d\theta$. Then

$$\oint_\gamma \frac{f(z)\,dz}{z-z_0} = \oint_{\gamma_r} \frac{f(z_0+re^{i\theta})}{re^{i\theta}} ire^{i\theta}\,d\theta$$

$$= \oint_{\gamma_r} f(z_0+re^{i\theta})i\,d\theta. \qquad (5)$$

But we are free to allow the radius r to shrink to 0, so

$$\oint_\gamma \frac{f(z)\,dz}{z - z_0} = \lim_{r\to 0} \oint_{\gamma_r} f(z_0 + re^{i\theta})i\,d\theta = \oint_{\gamma_r} f(z_0)i\,d\theta$$
$$= if(z_0) \oint_{\gamma_r} d\theta = 2\pi i f(z_0), \tag{6}$$

and

$$f(z_0) = \frac{1}{2\pi i} \oint_\gamma \frac{f(z)\,dz}{z - z_0}. \tag{7}$$

If multiple loops are made around the POLE, then equation (7) becomes

$$n(\gamma,\ z_0) f(z_0) = \frac{1}{2\pi i} \oint_\gamma \frac{f(z)\,dz}{z - z_0}, \tag{8}$$

where $n(\gamma,\ z_0)$ is the WINDING NUMBER.

A similar formula holds for the derivatives of $f(z)$,

$$f'(z_0) = \lim_{h\to 0} \frac{f(z_0 + h) - f(z_0)}{h}$$
$$= \lim_{h\to 0} \frac{1}{2\pi i h} \left[\oint_\gamma \frac{f(z)\,dz}{z - z_0 - h} - \oint_\gamma \frac{f(z)\,dz}{z - z_0} \right]$$
$$= \lim_{h\to 0} \frac{1}{2\pi i h} \oint_\gamma \frac{f(z)[(z - z_0) - (z - z_0 - h]\,dz}{(z - z_0 - h)(z - z_0)}$$
$$= \lim_{h\to 0} \frac{1}{2\pi i h} \oint_\gamma \frac{hf(z)\,dz}{(z - z_0 - h)(z - z_0)}$$
$$= \frac{1}{2\pi i} \oint_\gamma \frac{f(z)\,dz}{(z - z_0)^2}. \tag{9}$$

Iterating again,

$$f''(z_0) = \frac{2}{2\pi i} \oint_\gamma \frac{f(z)\,dz}{(z - z_0)^3}. \tag{10}$$

Continuing the process and adding the WINDING NUMBER n,

$$n(\gamma,\ z_0) f^{(r)}(z_0) = \frac{r!}{2\pi i} \oint_\gamma \frac{f(z)\,dz}{(z - z_0)^{r+1}}. \tag{11}$$

Cauchy Integral Test

INTEGRAL TEST

Cauchy Integral Theorem

If $f(z)$ is analytic in some simply connected region R, then

$$\oint_\gamma f(z)\,dz = 0 \tag{1}$$

for any closed CONTOUR γ completely contained in R. Writing z as

$$z \equiv x + iy \tag{2}$$

and $f(z)$ as

$$f(z) \equiv u + iv \tag{3}$$

then gives

$$\oint_\gamma f(z)\,dz = \int_\gamma (u + iv)(dx + i\,dy)$$
$$= \int_\gamma u\,dx - v\,dy + i\int_\gamma v\,dx + u\,dy. \tag{4}$$

From GREEN'S THEOREM,

$$\int_\gamma f(x,\ y)\,dx - g(x,\ y)\,dy = -\iint \left(\frac{\partial g}{\partial x} + \frac{\partial f}{\partial y} \right) dx\,dy, \tag{5}$$

$$\int_\gamma f(x,\ y)\,dx + g(x,\ y)\,dy = \iint \left(\frac{\partial g}{\partial x} - \frac{\partial f}{\partial y} \right) dx\,dy \tag{6}$$

so (4) becomes

$$\oint_\gamma f(z)\,dz = -\iint \left(\frac{\partial v}{\partial x} + \frac{\partial u}{\partial y} \right) dx\,dy$$
$$+ i \iint \left(\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) dx\,dy. \tag{7}$$

But the CAUCHY-RIEMANN EQUATIONS require that

$$\frac{\partial u}{\partial x} = \frac{\partial v}{\partial y} \tag{8}$$

$$\frac{\partial u}{\partial y} = -\frac{\partial v}{\partial x}, \tag{9}$$

so

$$\oint_{\gamma} f(z)\,dz = 0, \tag{10}$$

Q.E.D.

For a MULTIPLY CONNECTED region,

$$\oint_{C_1} f(z)\,dz = \oint_{C_2} f(z)\,dz. \tag{11}$$

Cauchy Problem

If $f(x, y)$ is an ANALYTIC FUNCTION in a NEIGHBORHOOD of the point (x_0, y_0) (i.e., it can be expanded in a series of NONNEGATIVE INTEGER POWERS of $(x - x_0)$ and $(y - y_0)$), find a solution $y(x)$ of the DIFFERENTIAL EQUATION

$$\frac{dy}{dx} = f(x),$$

with initial conditions $y = y_0$ and $x = x_0$. The existence and uniqueness of the solution were proven by Cauchy and Kovalevskaya in the CAUCHY-KOVALEVSKAYA THEOREM. The Cauchy problem amounts to determining the shape of the boundary and type of equation which yield unique and reasonable solutions for the CAUCHY BOUNDARY CONDITIONS.

See also CAUCHY BOUNDARY CONDITIONS, CAUCHY-KOVALEVSKAYA THEOREM

Cauchy Product

The Cauchy product of two sequences $f(n)$ and $g(n)$ defined for nonnegative integers n is defined by

$$(f \circ g)(n) = \sum_{k=0}^{n} f(k)g(n-k).$$

Cauchy Ratio Test

RATIO TEST

Cauchy Remainder

The remainder after n terms of a TAYLOR SERIES is given by

$$R_n = \frac{(x - x^*)^n (x - x_0)^{n+1}}{n!} f^{(n+1)}(x^*),$$

where $x^* \in (x_0, x)$.

Note that the Cauchy remainder R_n is also sometimes taken to refer to the remainder when terms up to the $(n-1)$st power are taken in the TAYLOR SERIES, and that a notation in which $h \to x - x_0$, $x^* \to a + \theta h$, and $x - x^* \to 1 - \theta$ is sometimes used (Blumenthal 1926; Whittaker and Watson 1990, pp. 95–96).

Cauchy Root Test

ROOT TEST

Cauchy Sequence

A SEQUENCE $a_1, a_2, \ldots$ such that the METRIC $d(a_m, a_n)$ satisfies

$$\lim_{\min(m,\, n)\to\infty} d(a_m, a_n) = 0.$$

Cauchy sequences in the rationals do not necessarily CONVERGE, but they do CONVERGE in the REALS.

REAL NUMBERS can be defined using either DEDEKIND CUTS or Cauchy sequences.

See also DEDEKIND CUT

Cauchy Test

RATIO TEST

Cauchy-Davenport Theorem

Let t be a NONNEGATIVE INTEGER and let $x_1, \ldots, x_t$ be nonzero elements of $\mathbb{Z}_p$ which are not necessarily distinct. Then the number of elements of $\mathbb{Z}_p$ that can be written as the sum of some SUBSET (possibly empty) of the x_i is at least $\min\{p, t+1\}$. In particular, if $t \geq p-1$, then every element of $\mathbb{Z}_p$ can be so written.

Cauchy-Frobenius Lemma

Let J be a FINITE GROUP and the image $R(J)$ be a representation which is a HOMEOMORPHISM of J into a PERMUTATION GROUP $S(X)$, where $S(X)$ is the GROUP of all permutations of a SET X. Define the orbits of $R(J)$ as the equivalence classes under $x \sim y$, which is true if there is some permutation p in $R(J)$ such that $p(x) = y$. Define the fixed points of p as the elements x of X for which $p(x) = x$. Then the AVERAGE number of FIXED POINTS of permutations in $R(J)$ is equal to the number of orbits of $R(J)$.

The LEMMA was apparently known by Cauchy (1845) in obscure form and Frobenius (1887) prior to Burnside's (1900) rediscovery. It is sometimes also called BURNSIDE'S LEMMA, the PÓLYA-BURNSIDE LEMMA, or even "the LEMMA THAT IS NOT BURNSIDE'S!" Whatever its name, the lemma was subsequently extended and refined by Pólya (1937) for applications in COMBINATORIAL counting problems. In this form, it is known as PÓLYA ENUMERATION THEOREM.

LAGRANGE'S IDENTITY

Cauchy-Maclaurin Theorem

MACLAURIN-CAUCHY THEOREM

Cauchy-Riemann Equations

Let

$$f(x, y) \equiv u(x, y) + iv(x, y), \tag{1}$$

where

$$z \equiv x + iy, \tag{2}$$

so

$$dz = dx + i\,dy. \tag{3}$$

The total derivative of f with respect to z may then be computed as follows.

$$y = \frac{z - x}{i} \tag{4}$$

$$x = z - iy, \tag{5}$$

so

$$\frac{\partial y}{\partial z} = \frac{1}{i} = -i \tag{6}$$

$$\frac{\partial x}{\partial z} = 1, \tag{7}$$

and

$$\frac{df}{dz} = \frac{\partial f}{\partial x}\frac{\partial x}{\partial z} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial z} = \frac{\partial f}{\partial x} - i\,\frac{\partial f}{\partial y}. \tag{8}$$

In terms of u and v, (8) becomes

$$\begin{aligned}\frac{df}{dz} &= \left(\frac{\partial u}{\partial x} + i\,\frac{\partial v}{\partial x}\right) - i\left(\frac{\partial u}{\partial y} + i\,\frac{\partial v}{\partial y}\right)\\ &= \left(\frac{\partial u}{\partial x} + i\,\frac{\partial v}{\partial x}\right) + \left(-i\,\frac{\partial u}{\partial y} + \frac{\partial v}{\partial y}\right).\end{aligned} \tag{9}$$

Along the real, or X-AXIS, $\partial f/\partial y = 0$, so

$$\frac{df}{dz} = \frac{\partial u}{\partial x} + i\,\frac{\partial v}{\partial x}. \tag{10}$$

Along the imaginary, or Y-AXIS, $\partial f/\partial x = 0$, so

$$\frac{df}{dz} = -i\,\frac{\partial u}{\partial y} + \frac{\partial v}{\partial y}. \tag{11}$$

If f is COMPLEX DIFFERENTIABLE, then the value of the derivative must be the same for a given dz, regardless of its orientation. Therefore, (10) must equal (11), which requires that

$$\frac{\partial u}{\partial x} = \frac{\partial v}{\partial y} \tag{12}$$

and

$$\frac{\partial v}{\partial x} = -\frac{\partial u}{\partial y}. \tag{13}$$

These are known as the Cauchy-Riemann equations. They lead to the condition

$$\frac{\partial^2 u}{\partial x\,\partial y} = -\frac{\partial^2 v}{\partial x\,\partial y}. \tag{14}$$

The Cauchy-Riemann equations may be concisely written as

$$\begin{aligned}\frac{df}{d\bar{z}} &= \frac{\partial f}{\partial x} + i\,\frac{\partial f}{\partial y} = \left(\frac{\partial u}{\partial x} + i\,\frac{\partial v}{\partial x}\right) + i\left(\frac{\partial u}{\partial y} + i\,\frac{\partial v}{\partial y}\right)\\ &= \left(\frac{\partial u}{\partial x} - \frac{\partial v}{\partial y}\right) + i\left(\frac{\partial u}{\partial y} + \frac{\partial v}{\partial x}\right) = 0,\end{aligned} \tag{15}$$

where $\bar{z}$ is the COMPLEX CONJUGATE.

If $z = re^{i\theta}$, then the Cauchy-Riemann equations become

$$\frac{\partial u}{\partial r} = \frac{1}{r}\frac{\partial v}{\partial \theta} \tag{16}$$

$$\frac{1}{r}\frac{\partial u}{\partial \theta} = -\frac{\partial v}{\partial r} \tag{17}$$

(Abramowitz and Stegun 1972, p. 17).

If u and v satisfy the Cauchy-Riemann equations, they also satisfy LAPLACE'S EQUATION in 2-D, since

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = \frac{\partial}{\partial x}\left(\frac{\partial v}{\partial y}\right) + \frac{\partial}{\partial y}\left(-\frac{\partial v}{\partial x}\right) = 0 \tag{18}$$

$$\frac{\partial^2 v}{\partial x^2} + \frac{\partial^2 v}{\partial y^2} = \frac{\partial}{\partial x}\left(-\frac{\partial u}{\partial y}\right) + \frac{\partial}{\partial y}\left(\frac{\partial u}{\partial x}\right) = 0. \tag{19}$$

By picking an arbitrary $f(z)$, solutions can be found which automatically satisfy the Cauchy-Riemann equations and LAPLACE'S EQUATION. This fact is used to use CONFORMAL MAPPINGS to find solutions to physical problems involving scalar potentials such as fluid flow and electrostatics.

Cauchy's Cosine Integral Formula

$$\int_{-\pi/2}^{\pi/2} \cos^{\mu+\nu-2}\theta e^{i\theta(\mu-\nu+2\xi)}\,d\theta = \frac{\pi\Gamma(\mu+\nu-1)}{2^{\mu+\nu-2}\Gamma(\mu+\xi)\Gamma(\nu-\xi)},$$

where $\Gamma(z)$ is the GAMMA FUNCTION.

Cauchy's Determinant Theorem

Any row r and column s of a DETERMINANT being selected, if the element common to them be multiplied by its COFACTOR in the DETERMINANT, and every product of another element of the row by another element of the columns be multiplied by its COFACTOR, the sum of the results is equal to the given DETERMINANT. Symbolically,

$$\Delta = a_{rs}\frac{\partial\Delta}{\partial a_{rs}} + \sum a_{ri}a_{ks}\frac{\partial^2\Delta}{\partial a_{ri}\,\partial a_{ks}} \quad (1)$$

$$= (-1)^{r+s}a_{rs}A_{rs} + \sum \pm a_{ri}a_{ks}A_{rk,\,is}, \quad (2)$$

where $i,\ k = 1, 2, ..., n;\ i \neq s;\ k \neq r$; and the sign before $a_{ri}a_{ks}A_{rk,\,is}$ is determined by the formula $(-1)^{\nu_1+\nu_2}$, with ν_1 the total number of PERMUTATION INVERSIONS in the suffix and $\nu_2 = r+i+k+s$.

See also DETERMINANT

Muir, T. "Cauchy's Theorem." §110 in *A Treatise on the Theory of Determinants.* New York: Dover, pp. 95–96, 1960.

Cauchy's Formula

The GEOMETRIC MEAN is smaller than the ARITHMETIC MEAN,

$$\left(\prod_{i=1}^{N} n_i\right)^{1/N} \leq \frac{\sum_{i=1}^{N} n_i}{N},$$

with equality in the cases (1) $N=1$ or (2) $n_i = n_j$ for all i, j.

See also ARITHMETIC MEAN, GEOMETRIC MEAN

Cauchy's Inequality

A special case of HÖLDER'S SUM INEQUALITY with $p = q = 2$,

$$\left(\sum_{k=1}^{n} a_k b_k\right)^2 \leq \left(\sum_{k=1}^{n} a_k^2\right)\left(\sum_{k=1}^{n} b_k^2\right), \quad (1)$$

where equality holds for $a_k = cb_k$. The inequality is sometimes also called Lagrange's inequality (Mitrinovic 1970, p. 42), and can be written in vector form as

$$|\mathbf{a}\cdot\mathbf{b}| \leq |\mathbf{a}||\mathbf{b}|. \quad (2)$$

In 2-D, it becomes

$$(a^2+b^2)(c^2+d^2) \geq (ac+bd)^2. \quad (3)$$

It can be proven by writing

$$\sum_{i=1}^{n}(a_i x + b_i)^2 = \sum_{i=1}^{n} a_i^2\left(x + \frac{b_i}{a_i}\right)^2 = 0. \quad (4)$$

If b_i/a_i is a constant c, then $x = -c$. If it is not a constant, then all terms cannot simultaneously vanish for REAL x, so the solution is COMPLEX and can be found using the QUADRATIC EQUATION

$$x = \frac{-2\sum a_i b_i \pm \sqrt{4(\sum a_i b_i)^2 - 4\sum a_i^2 \sum b_i^2}}{2\sum a_i^2}. \quad (5)$$

In order for this to be COMPLEX, it must be true that

$$\left(\sum_i a_i b_i\right)^2 \leq \left(\sum_i a_i^2\right)\left(\sum_i b_i^2\right), \quad (6)$$

with equality when b_i/a_i is a constant. The VECTOR derivation is much simpler,

$$(\mathbf{a}\cdot\mathbf{b})^2 = a^2 b^2 \cos^2\theta \leq a^2 b^2, \quad (7)$$

where

$$a^2 \equiv \mathbf{a}\cdot\mathbf{a} = \sum_i a_i^2, \quad (8)$$

and similarly for b.

Cayley Cubic

A cubic ruled surface (Fischer 1986) in which the director line meets the director conic section. Cayley's surface is the unique cubic surface having four ordinary double points (Hunt), the maximum possible for cubic surface (Endraß). The Cayley cubic is invariant under the tetrahedral group and contains exactly nine lines, six of which connect the four nodes pairwise and the other three of which are coplanar (Endraß).

If the ordinary double points in projective 3-space are taken as (1, 0, 0, 0), (0, 1, 0, 0), (0, 0, 1, 0), (0, 0, 0, 1), then the equation of the surface in projective coordinates is

$$\frac{1}{x_0}+\frac{1}{x_1}+\frac{1}{x_2}+\frac{1}{x_3}=0 \tag{1}$$

(Hunt). Defining "affine" coordinates with plane at infinity $v=x_0+x_1+x_2+2x_3$ and

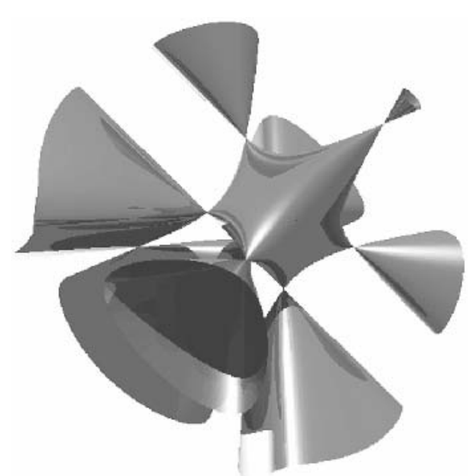
$$x=\frac{x_0}{v} \tag{2}$$

$$y=\frac{x_1}{v} \tag{3}$$

$$z=\frac{x_2}{v} \tag{4}$$

then gives the equation

$$-5(x^2y+x^2z+y^2x+y^2z+z^2y+z^2x)+2(xy+xz+yz)=0 \tag{5}$$



plotted in the left figure above (Hunt). The slightly different form

$$4(x^3+y^3+z^3+w^3)-(x+y+z+w)^3=0 \tag{6}$$

is given by Endraß which, when rewritten in tetrahedral coordinates, becomes

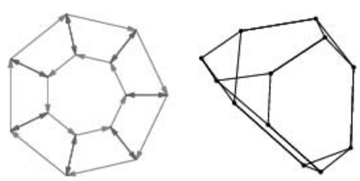
$$x^2+y^2-x^2z+y^2z+z^2-1=0, \tag{7}$$

plotted in the right figure above.

The Hessian of the Cayley cubic is given by

$$\begin{aligned}0=&x_0^2(x_1x_2+x_1x_3+x_2x_3)+x_1^2(x_0x_2+x_0x_3+x_2x_3)\\&+x_2^2(x_0x_1+x_0x_3+x_1x_3)+x_3^2(x_0x_1+x_0x_2+x_1x_2)\end{aligned} \tag{8}$$

in homogeneous coordinates x_0, x_1, x_2, and x_3. Taking the plane at infinity as $v=5(x_0+x_1+x_2+2x_3)/2$ and setting x, y, and z as above gives the equation



$$\begin{aligned}&25[x^3(y+z)+y^3(x+z)+z^3(x+y)]+50(x^2y^2+x^2z^2+y^2z^2)\\&-125(x^2yz+y^2xz+z^2xy)+60xyz-4(xy+xz+yz)=0,\end{aligned} \tag{9}$$

plotted above (Hunt). The Hessian of the Cayley cubic has 14 ordinary double points, four more than a the general Hessian of a smooth cubic surface (Hunt).

Cayley Graph

The Cayley graph of a GROUP G is a DIRECTED GRAPH determined by a set of generators g_1, ..., g_k. The vertices correspond to the elements of the group, and whenever $g_i a = b$, an edge is drawn between a and b. For example, the DIHEDRAL GROUP D_7 (left figure) is generated by the two elements, flips (red) and rotations (blue). The Cayley graph depends on the choice of a generating set. The right figure above illustrates the Cayley graph for the ALTERNATING GROUP A_4.
Royle has constructed all cubic Cayley graphs up to 1000 vertices, excluding those on 512 and 768 vertices.

The Cayley graphs of infinite groups provide interesting geometries. For example, the Cayley graphs of the FREE GROUP on two generators are illustrated above (drawn out to successive levels), representing horizontal and vertical displacement respectively. Each new edge is drawn at half the size to give FRACTAL images.

Cayley Lines

The 60 PASCAL LINES of a hexagon inscribed in a conic intersect three at a time through 20 STEINER POINTS, and also three at a time in 60 KIRKMAN POINTS. Each STEINER POINT lies together with three KIRKMAN POINTS on a total of 20 lines known as Cayley lines. The 20 Cayley lines pass four at a time though 15 points known as SALMON POINTS (Wells 1991). There is a dual relationship between the 20 Cayley lines and the 20 STEINER POINTS.

Cayley Number

There are two completely different definitions of Cayley numbers. The first and most commonly encountered type of Cayley number is the eight elements in a CAYLEY ALGEBRA, also known as octonions. The set of octonions is sometimes denoted $\mathbb{O}$. A typical Cayley number is OF THE FORM

$$a + bi_0 + ci_1 + di_2 + ei_3 + fi_4 + gi_5 + hi_6,$$

where each of the triples (i_0, i_1, i_3), (i_1, i_2, i_4), (i_2, i_3, i_5), (i_3, i_4, i_6), (i_4, i_5, i_0), (i_5, i_6, i_1), (i_6, i_0, i_2) behaves like the QUATERNIONS (i, j, k). Cayley numbers are *not* ASSOCIATIVE. They have been used in the study of 7- and 8-D space, and a general rotation in 8-D space can be written

$$x' \to ((((((xc_1)c_2)c_3)c_4)c_5)c_6)c_7.$$

A quantity which describes a DEL PEZZO SURFACE is sometimes also called a Cayley number (Coxeter 1973, p. 211).

Cayley Surface

In affine 3-space the Cayley surface is given by

$$x_3 = x_1 x_2 - \tfrac{1}{3} x_1^3$$

(Nomizu and Sasaki 1994). The surface has been generalized by Eastwood and Ezhov (2000) to

$$\Phi_N(x_1,\ x_2,\ \ldots,\ x_N) \equiv \sum_{d=1}^{N} (-1)^d \sum_{i+j+\ldots+m=N} \underbrace{x_i x_j \ldots x_m}_{d} = 0.$$

This gives the first few hypersurfaces as

$$x_4 = x_1 x_3 + \tfrac{1}{2} x_2^2 - x_1^2 x_2 + \tfrac{1}{4} x_1^4$$

$$x_5 = x_1 x_4 + x_2 x_3 - x_1^2 x_3 - x_1 x_2^2 + x_1^3 x_2 - \tfrac{1}{5} x_1^5.$$

Cayley Tree

A tree in which each non-leaf node has a constant number of branches n is called an n-Cayley tree. 2-Cayley trees are path graphs. The unique n-Cayley tree on $n+1$ nodes is the star graph. The illustration above shows the first few 3-Cayley trees (also called trivalent trees, binary trees, or boron trees). The numbers of binary trees on $n = 1, 2, \ldots$ nodes (i.e., n-node trees having vertex degree either 1 or 3; also called 3-Cayley trees, 3-valent trees, or boron trees) are 1, 1, 0, 1, 0, 1, 0, 1, 0, 2, 0, 2, 0 ,4, 0, 6, 0, 11, ... (Sloane's A052120).

The illustrations above show the first few 4-Cayley and 5-Cayley trees.

The percolation threshold for a Cayley tree having z branches is

$$p_c = \frac{1}{z-1}.$$

Cayley-Bacharach Theorem

Let $X_1,\ X_2 \subset \mathbb{P}^2$ be cubic plane curves meeting in nine points $p_1, \ldots, p_9$. If $X \subset \mathbb{P}^2$ is any cubic containing $p_1, \ldots, p_8$, then X contains p_9 as well. It is related to Gorenstein rings, and is a generalization of Pappus's hexagon theorem and Pascal's theorem.

Cayley-Dickson Algebra

CAYLEY ALGEBRA

Cayley-Hamilton Theorem

Given

$$\begin{vmatrix} a_{11}-x & a_{12} & \cdots & a_{1m} \\ a_{21} & a_{22}-x & \cdots & a_{2m} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & \cdots & a_{mm}-x \end{vmatrix} = x^m + c_{m-1}x^{m-1} + \ldots + c_0, \quad (1)$$

then

$$\mathsf{A}^m + c_{m-1}\mathsf{A}^{m-1} + \ldots + c_0\mathsf{I} = 0, \quad (2)$$

where I is the IDENTITY MATRIX. Cayley verified this identity for $m = 2$ and 3 and postulated that it was true for all m. For $m = 2$, direct verification gives

$$\begin{vmatrix} a-x & b \\ c & d-x \end{vmatrix} = (a-x)(d-x) - bc = x^2 - (a+d)x + (ad-bc) \equiv x^2 + c_1 x + c_2 \quad (3)$$

$$\mathsf{A} = \begin{bmatrix} a & b \\ c & d \end{bmatrix} \quad (4)$$

$$\mathsf{A}^2 = \begin{bmatrix} a & b \\ c & d \end{bmatrix}\begin{bmatrix} a & b \\ c & d \end{bmatrix} = \begin{bmatrix} a^2+bc & ab+bd \\ ac+cd & bc+d^2 \end{bmatrix} \quad (5)$$

$$-(a+d)\mathsf{A} = \begin{bmatrix} -a^2-ad & -ab-bd \\ -ac-dc & -ad-d^2 \end{bmatrix} \quad (6)$$

$$(ad-bc)\mathsf{I} = \begin{bmatrix} ad-bc & 0 \\ 0 & ad-bc \end{bmatrix}, \quad (7)$$

so

$$\mathsf{A}^2 - (a+d)\mathsf{A} + (ad-bc)\mathsf{I} = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}. \quad (8)$$

The Cayley-Hamilton theorem states that a $n \times n$ MATRIX A is annihilated by its CHARACTERISTIC POLYNOMIAL $\det(x\mathsf{I} - \mathsf{A})$, which is monic of degree n.

Cayleyian Curve

The ENVELOPE of the lines connecting corresponding points on the JACOBIAN CURVE and STEINERIAN CURVE. The Cayleyian curve of a net of curves of order n has the same GENUS (CURVE) as the JACOBIAN CURVE and STEINERIAN CURVE and, in general, the class $3n(n-1)$.

Coolidge, J. L. *A Treatise on Algebraic Plane Curves.* New York: Dover, p. 150, 1959.

Cayley-Klein Parameters

The parameters α, β, γ, and δ which, like the three EULER ANGLES, provide a way to uniquely characterize the orientation of a solid body. These parameters satisfy the identities

$$\alpha\bar{\alpha} + \gamma\bar{\gamma} = 1 \quad (1)$$

$$\alpha\bar{\alpha} + \beta\bar{\beta} = 1 \quad (2)$$

$$\beta\bar{\beta} + \delta\bar{\delta} = 1 \quad (3)$$

$$\bar{\alpha}\beta + \bar{\gamma}\delta = 0 \quad (4)$$

$$\alpha\delta - \beta\gamma = 1 \quad (5)$$

and

$$\beta = -\bar{\gamma} \quad (6)$$

$$\delta = \bar{\alpha}, \quad (7)$$

where $\bar{z}$ denotes the COMPLEX CONJUGATE. In terms of the EULER ANGLES θ, ϕ, and ψ, the Cayley-Klein parameters are given by

$$\alpha = e^{i(\psi+\phi)/2}\cos(\tfrac{1}{2}\theta) \quad (8)$$

$$\beta = ie^{i(\psi+\phi)/2}\sin(\tfrac{1}{2}\theta) \quad (9)$$

$$\gamma = ie^{i(\psi+\phi)/2}\sin(\tfrac{1}{2}\theta) \quad (10)$$

$$\delta = e^{i(\psi+\phi)/2}\cos(\tfrac{1}{2}\theta) \quad (11)$$

(Goldstein 1960, p. 155).

The transformation matrix is given in terms of the Cayley-Klein parameters by

$$\mathsf{A} = \begin{bmatrix} \tfrac{1}{2}(\alpha^2-\gamma^2+\delta^2-\beta^2) & \tfrac{1}{2}i(\gamma^2-\alpha^2+\delta^2-\beta^2) & \gamma\delta-\alpha\beta \\ \tfrac{1}{2}i(\alpha^2+\gamma^2-\beta^2-\delta^2) & \tfrac{1}{2}(\alpha^2+\gamma^2+\beta^2+\delta^2) & -i(\alpha\beta+\gamma\delta) \\ \beta\delta-\alpha\gamma & i(\alpha\gamma+\beta\delta) & \alpha\delta+\beta\gamma \end{bmatrix} \quad (12)$$

(Goldstein 1960, p. 153).

The Cayley-Klein parameters may be viewed as parameters of a matrix (denoted Q for its close relationship with QUATERNIONS)

$$\mathsf{Q} = \begin{bmatrix} \alpha & \beta \\ \gamma & \delta \end{bmatrix} \quad (13)$$

which characterizes the transformations

$$u' = \alpha u + \beta v \quad (14)$$

$$v' = \gamma u + \delta v. \quad (15)$$

of a linear space having complex axes. This matrix satisfies

$$Q^* Q = Q Q^* = I, \quad (16)$$

where I is the IDENTITY MATRIX and A^* the ADJOINT MATRIX, as well as

$$|Q|^* |Q| = 1. \quad (17)$$

In terms of the EULER PARAMETERS e_i and the PAULI MATRICES σ_i, the Q-matrix can be written as

$$Q = e_0 I + i(e_1\sigma_1 + e_2\sigma_2 + e_3\sigma_3) \quad (18)$$

(Goldstein 1980, p. 156).

Cayley-Klein-Hilbert Metric

The METRIC of Felix Klein's model for HYPERBOLIC GEOMETRY,

$$g_{11} = \frac{a^2(1 - x_2^2)}{(1 - x_1^2 - x_2^2)^2}$$

$$g_{12} = \frac{a^2 x_1 x_2}{(1 - x_1^2 - x_2^2)^2}$$

$$g_{22} = \frac{a^2(1 - x_1^2)}{(1 - x_1^2 - x_2^2)^2}.$$

See also HYPERBOLIC GEOMETRY

Cayley-Menger Determinant

This entry contributed by KAREN D. COLLINS

A DETERMINANT that gives the volume of a SIMPLEX in j dimensions. If S is a j-simplex in $\mathbb{R}^n$ with vertices $v_1, \ldots, v_j + 1$ and $B = (\beta_{ik})$ denotes the $(j+1) \times (j+1)$ matrix given by

$$\beta_{ik} = \|v_i - v_k\|_2^2, \quad (1)$$

then the CONTENT V_j is given by

$$V_j^2(S) = \frac{(-1)^{j+1}}{2^j (j!)^2} \det(\hat{B}), \quad (2)$$

where $\hat{B}$ is the $(j+2) \times (j+2)$ matrix obtained from B by bordering B with a top row $(0, 1, \ldots, 1)$ and a left column $(0, 1, \ldots, 1)^T$. Here, the vector L^2-NORMS $\|v_i - v_k\|_2$ are the edge lengths and the DETERMINANT in (2) is the Cayley-Menger determinant (Sommerville 1958, Gritzmann and Klee 1994). The first few coefficients for $j = 0, 1, \ldots$ are $-1, 2, -16, 288, -9216, 460800, \ldots$ (Sloane's A055546).

For $j = 2$, (2) becomes

$$-16\Delta^2 = \begin{vmatrix} 0 & 1 & 1 & 1 \\ 1 & 0 & c^2 & b^2 \\ 1 & c^2 & 0 & a^2 \\ 1 & b^2 & a^2 & 0 \end{vmatrix}, \quad (3)$$

which gives the AREA for a plane triangle with side lengths a, b, and c, and is a form of HERON'S FORMULA.

For $j = 3$, the content of the 3-simplex (i.e., volume of the general TETRAHEDRON) is given by the determinant

$$288V^2 = \begin{vmatrix} 0 & 1 & 1 & 1 & 1 \\ 1 & 0 & d_{12}^2 & d_{13}^2 & d_{14}^2 \\ 1 & d_{21}^2 & 0 & d_{23}^2 & d_{24}^2 \\ 1 & d_{31}^2 & d_{32}^2 & 0 & d_{34}^2 \\ 1 & d_{41}^2 & d_{42}^2 & d_{43}^2 & 0 \end{vmatrix}, \quad (4)$$

where the edge between vertices i and j has length d_{ij}. Setting the left side equal to 0 (corresponding to a TETRAHEDRON of volume 0) gives a relationship between the DISTANCES between vertices of a planar QUADRILATERAL (Uspensky 1948, p. 256).

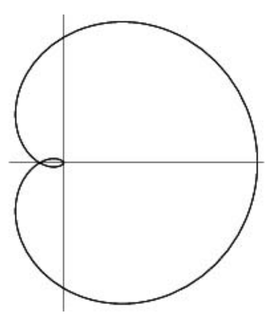
Cayley's Hypergeometric Function Theorem

If

$$(1-z)^{a+b-c}\,{}_2F_1(2a,\ 2b;\ 2c;\ z)=\sum_{n=0}^{\infty} a_n z^n,$$

then

$$ {}_2F_1(a,\ b;\ c+\tfrac{1}{2};\ z)\,{}_2F_1(c-a,\ c-b;\ c\tfrac{1}{2};\ z) = \sum_{n=0}^{\infty} \frac{(c)_n}{(c+\frac{1}{2})}\, a_n z^n, $$



where ${}_2F_1(a,\ b;\ c;\ z)$ is a HYPERGEOMETRIC FUNCTION.

See also HYPERGEOMETRIC FUNCTION

Cayley's Ruled Surface

CAYLEY CUBIC

Cayley's Sextic

A plane curve discovered by Maclaurin but first studied in detail by Cayley. The name Cayley's sextic is due to R. C. Archibald, who attempted to classify curves in a paper published in Strasbourg in 1900 (MacTutor Archive). Cayley's sextic is given in POLAR COORDINATES by

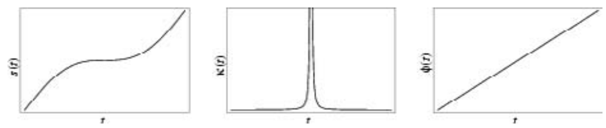
$$r=4a\cos^3(\tfrac{1}{3}\theta). \tag{1}$$

Parametric equations can be given by

$$x(t)=4a\cos^4(\tfrac{1}{2}t)(2\cos t-1) \tag{2}$$

$$y(t)=4a\cos^3(\tfrac{1}{2}t)\sin(\tfrac{3}{2}t) \tag{3}$$

(Gray 1997, p. 119). Calculating r gives



$$r=\sqrt{x^2+y^2}=4\cos^3(\tfrac{1}{2}t), \tag{4}$$

and t is related to θ by

$$\theta=\tan^{-1}\left(\frac{y}{x}\right)=\tfrac{3}{2}t, \tag{5}$$

thus recovering (1). The CARTESIAN equation is

$$4(x^2+y^2-ax)^3=27a^2(x^2+y^2)^2. \tag{6}$$

The ARC LENGTH, CURVATURE, and TANGENTIAL ANGLE for the curve with $a=1$ are

$$s(t)=3(t+\sin t), \tag{7}$$

$$\kappa(t)=\tfrac{1}{3}\sec^2(\tfrac{1}{2}t), \tag{8}$$

$$\phi(t)=2t. \tag{9}$$

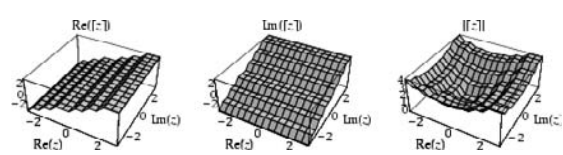
Cech Cohomology



The direct limit of the COHOMOLOGY groups with COEFFICIENTS in an ABELIAN GROUP of certain coverings of a TOPOLOGICAL SPACE.

Ceiling

CEILING FUNCTION

Ceiling Function

The function $\lceil x \rceil$ which gives the smallest INTEGER $\geq x$, shown as the thick curve in the above plot. Schroeder (1991) calls the ceiling function symbols the "GALLOWS" because of the similarity in appearance to the structure used for hangings. The name and symbol for the ceiling function were coined by K. E. Iverson (Graham *et al.* 1990). Although some authors used the symbol $]x[$ to denote the ceiling function (by analogy with the older notation $[x]$ for the FLOOR FUNCTION), this practice is strongly discouraged (Graham *et al.* 1990, p. 67).

Since usage concerning fractional part/value and integer part/value can be confusing, the following table gives a summary of names and notations used (D. W. Cantrell). Here, S&O indicates Spanier and Oldham (1987).

notation	name	S&O	Graham *et al.*	*Mathematica*
$\lfloor x \rfloor$	integer-value	Int(x)	floor or integer part	`Floor[x]`
$\mathrm{sgn}(x)\lfloor \lvert x \rvert \rfloor$	integer-part	Ip(x)	no name	`IntegerPart[x]`
$x - \lfloor x \rfloor$	fractional-value	frac(x)	fractional part or $\{x\}$	no name
$\mathrm{sgn}(x)(\lvert x \rvert - \lfloor \lvert x \rvert \rfloor)$	fractional-part	Fp(x)	no name	`FractionalPart[x]`

Odlyzko and Wilf (1991) have shown that the sequence $\{x_n\}$ defined by $x_0 = 1$ and

$$x_{n+1} = \left\lceil \tfrac{3}{2} x_n \right\rceil$$

satisfies

$$x_n = \left\lfloor K(\tfrac{3}{2})^n \right\rfloor$$

for all n, where $K = 1.6222705028\ldots$ is analogous to MILLS' CONSTANT in the sense that the formula is useless unless K is known exactly ahead of time (Finch).

Cellular Automaton

A cellular automaton is a grid (possibly 1-D) of cells which evolves according to a set of rules based on the states of surrounding cells. von Neumann was one of the first people to consider such a model, and incorporated a cellular model into his "universal constructor." von Neumann proved that an automaton consisting of cells with four orthogonal neighbors and 29 possible states would be capable of simulating a TURING MACHINE for some configuration of about 200,000 cells (Gardner 1983, p. 227).

1-D automata called "ELEMENTARY CELLULAR AUTOMATA" are represented by a row of pixels with states

either 0 or 1. These can be indexed with an 8-bit binary number, as shown by Stephen Wolfram. Wolfram further restricted the number from $2^8 = 256$ to 32 by requiring certain symmetry conditions.

The most well-known cellular automaton is Conway's game of LIFE, popularized in Martin Gardner's *Scientific American* columns. Although the computation of successive LIFE generations was originally done by hand, the computer revolution soon arrived and allowed more extensive patterns to be studied and propagated.

Cellular Space

A HAUSDORFF SPACE which has the structure of a so-called CW-COMPLEX.

Center

A special POINT which usually has some symmetric placement with respect to points on a curve or in a SOLID. The center of a CIRCLE is equidistant from all points on the CIRCLE and is the intersection of any two distinct DIAMETERS. The same holds true for the center of a SPHERE.

See also CENTER (GROUP), CENTER OF MASS, CIRCLE, CIRCUMCENTER, CLEAVANCE CENTER, CURVATURE CENTER, ELLIPSE, EQUI-BROCARD CENTER, EXCENTER, FUHRMANN CENTER, HOMOTHETIC CENTER, INCENTER, INVERSION CENTER, MAJOR TRIANGLE CENTER, NINE-POINT CENTER, ORTHOCENTER, PERSPECTIVE CENTER, POINT, RADICAL CENTER, SIMILITUDE CENTER, SPHERE, SPIEKER CENTER, TAYLOR CENTER, TRIANGLE CENTER, TRIANGLE CENTER FUNCTION, YFF CENTER OF CONGRUENCE

Center (Group)

The center of a GROUP is the set of elements which commute with every element of the GROUP. It is equal to the intersection of the CENTRALIZERS of the GROUP elements.

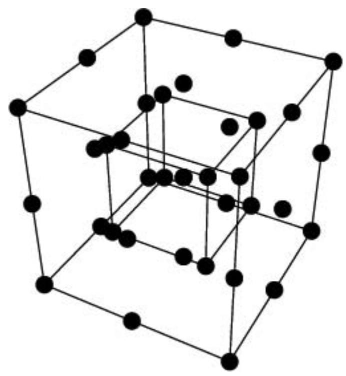
Center Function

TRIANGLE CENTER FUNCTION

Center of Gravity

CENTROID (GEOMETRIC)



Center of Mass

CENTROID (GEOMETRIC)

Center of Similitude

SIMILITUDE CENTER

Centered Cube Number

A FIGURATE NUMBER OF THE FORM,

$$CCub_n = n^3 + (n-1)^3 = (2n-1)(n^2 - n + 1).$$

The first few are 1, 9, 35, 91, 189, 341, ... (Sloane's A005898). The GENERATING FUNCTION for the centered cube numbers is

$$\frac{x(x^3 + 5x^2 + 5x + 1)}{(x-1)^4} = x + 9x^2 + 35x^3 + 91x^4 + \ldots.$$

See also CUBIC NUMBER

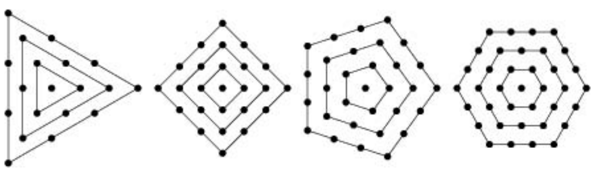
Centered Hexagonal Number

HEX NUMBER

Centered Pentagonal Number

A CENTERED POLYGONAL NUMBER consisting of a central dot with five dots around it, and then additional dots in the gaps between adjacent dots. The general term is $(5n^2 - 5n + 2)/2$, and the first few such numbers are 1, 6, 16, 31, 51, 76, ... (Sloane's A005891). The GENERATING FUNCTION of the centered pentagonal numbers is



$$\frac{x(x^2 + 3x + 1)}{(1-x)^3} = x + 6x^2 + 16x^3 + 31x^4 + \ldots.$$

See also CENTERED POLYGONAL NUMBER, CENTERED SQUARE NUMBER, CENTERED TRIANGULAR NUMBER, HEX NUMBER

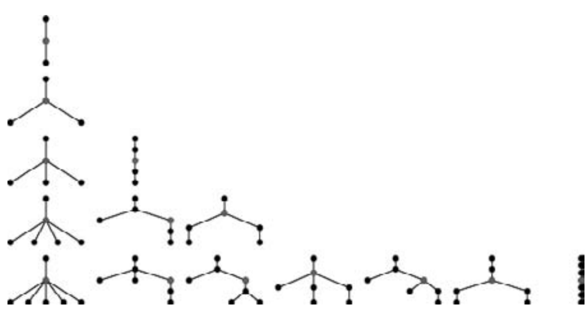
Centered Square Number

A CENTERED POLYGONAL NUMBER consisting of a central dot with four dots around it, and then additional dots in the gaps between adjacent dots. The general term is $n^2 + (n-1)^2$, and the first few

such numbers are 1, 5, 13, 25, 41, ... (Sloane's A001844). Centered square numbers are the sum of two consecutive SQUARE NUMBERS and are congruent to 1 (mod 4). The GENERATING FUNCTION giving the centered square numbers is

$$\frac{x(x+1)^2}{(1-x)^3} = x + 5x^2 + 13x^3 + 25x^4 + \ldots.$$



See also CENTERED PENTAGONAL NUMBER, CENTERED POLYGONAL NUMBER, CENTERED TRIANGULAR NUMBER, SQUARE NUMBER

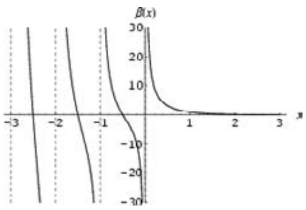
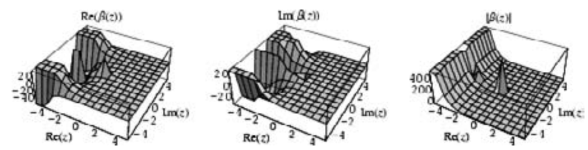
Central Angle

An ANGLE having its VERTEX at a CIRCLE's center which is formed by two points on the CIRCLE'S CIRCUMFERENCE. For angles with the same endpoints,



$$\theta_c = 2\theta_i,$$



where θ_i is the INSCRIBED ANGLE.

Central Beta Function

The central beta function is defined by

$$\beta(p) \equiv B(p,\ p), \tag{1}$$

where $B(p,\ q)$ is the BETA FUNCTION. It satisfies the identities

$$\beta(p) = 2^{1-2p} B(p,\ \tfrac{1}{2}) \tag{2}$$

$$= 2^{1-2p} \cos(\pi p)(\tfrac{1}{2} - p,\ p) \tag{3}$$

$$= \int_0^1 \frac{t^p dt}{(1+t)^{2p}} \tag{4}$$

$$\frac{2}{p} \prod_{n=1}^{\infty} \frac{n(n+2p)}{(n+p)(n+p)}. \tag{5}$$

With $p = 1/2$, the latter gives the WALLIS FORMULA. When $p = a/b$,

$$b\beta(a/b) = 2^{1-2a/b} J(a,\ b), \tag{6}$$

where

$$J(a,\ b) \equiv \int_0^1 \frac{t^{\alpha-1}\, dt}{\sqrt{1-t^b}}. \tag{7}$$

The central beta function satisfies

$$(2+4x)\beta(1+x) = x\beta(x) \tag{8}$$

$$(1-2x)\beta(1-x)\beta(x) = 2\pi \cot(\pi x) \tag{9}$$

$$\beta(\tfrac{1}{2} - x) = 2^{4x-1} \tan(\pi x)\beta(x) \tag{10}$$

$$\beta(x)\beta(x + \tfrac{1}{2}) = 2^{4x+1} \pi \beta(2x)\beta(2x + \tfrac{1}{2}). \tag{11}$$

For p an ODD POSITIVE INTEGER, the central beta function satisfies the identity

$$\beta(px) = \frac{1}{\sqrt{p}} \prod_{k=1}^{(p-1)/2} \frac{2x + \dfrac{2k-1}{p}}{2\pi} \prod_{k=0}^{p-1} \beta\left(x + \frac{k}{p}\right). \tag{12}$$

Central Binomial Coefficient

The nth central binomial coefficient is defined as $\binom{n}{\lfloor n/2 \rfloor}$, where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT and $\lfloor n \rfloor$ is the FLOOR FUNCTION. The first few values are 1, 2, 3, 6, 10, 20, 35, 70, 126, 252, ... (Sloane's A001405). The central binomial coefficients have GENERATING FUNCTION

$$\frac{1 - 4x^2 - \sqrt{1-4x^2}}{2(2x^3 - x^2)} = 1 + 2x + 3x^2 + 6x^3 + 10x^4 + \ldots.$$

The central binomial coefficients are SQUAREFREE only for $n = 1$, 2, 3, 4, 5, 7, 8, 11, 17, 19, 23, 71, ... (Sloane's A046098), with no others less than 7320.

The above coefficients are a superset of the alternative "central" binomial coefficients

$$\binom{2n}{n} = \frac{(2n)!}{(n!)^2},$$

which have GENERATING FUNCTION

$$\frac{1}{\sqrt{1-4x}} = 1 + 2x + 6x^2 + 20x^3 + 70x^4 + \ldots.$$

The first few values are 2, 6, 20, 70, 252, 924, 3432, 12870, 48620, 184756, ... (Sloane's A000984).

A fascinating series of identities involving inverse central binomial coefficients times small powers are given by

$$\sum_{n=1}^{\infty} \frac{1}{\binom{2n}{n}} = \tfrac{1}{27}(2\pi\sqrt{3} + 9) = 0.7363998587\ldots \tag{1}$$

$$\sum_{n=1}^{\infty} \frac{1}{n\binom{2n}{n}} = \tfrac{1}{9}\pi\sqrt{3} = 0.6045997881\ldots \tag{2}$$

$$\sum_{n=1}^{\infty} \frac{1}{n^2\binom{2n}{n}} = \tfrac{1}{3}\zeta(2) = \tfrac{1}{8}\pi^2 \tag{3}$$

$$\sum_{n=1}^{\infty} \frac{1}{n^4 \binom{2n}{n}} = \tfrac{17}{36}\zeta(4) = \tfrac{17}{3240}\pi^4 \quad (4)$$

(Comtet 1974, p. 89; Le Lionnais 1983, pp. 29, 30, 41, 36), which follow from the beautiful formula

$$\sum_{n=1}^{\infty} \frac{1}{n^k \binom{2n}{n}} = \tfrac{1}{2}{}_{k+1}F_k(\underbrace{1, \ldots, 1}_{k+1}; \tfrac{3}{2}, \underbrace{2, \ldots, 2}_{k-1}; \tfrac{1}{4}). \quad (5)$$

for $k \geq 1$, where ${}_mF_n(a_1, \ldots, a_m; b_1, \ldots, b_n; x)$ is a GENERALIZED HYPERGEOMETRIC FUNCTION. Additional sums of this type include

$$\sum_{n=1}^{\infty} \frac{1}{n^3 \binom{2n}{n}} = \tfrac{1}{18}\pi\sqrt{3}[\psi_1(\tfrac{1}{3}) - \psi_1(\tfrac{2}{3})] - \tfrac{4}{3}\zeta(3) \quad (6)$$

$$\sum_{n=1}^{\infty} \frac{1}{n^5 \binom{2n}{n}} = \tfrac{1}{432}\pi\sqrt{3}[\psi_3(\tfrac{1}{3}) - \psi_3(\tfrac{2}{3})] - \tfrac{19}{3}\zeta(5) + \tfrac{1}{9}\zeta(3)\pi^3, \quad (7)$$

$$\sum_{n=1}^{\infty} \frac{1}{n^7 \binom{2n}{n}} = \tfrac{11}{311040}\pi\sqrt{3}[\psi_5(\tfrac{1}{3}) - \psi_5(\tfrac{2}{3})] - \tfrac{493}{24}\zeta(7) + \tfrac{1}{3}\zeta(5)\pi^2 + \tfrac{17}{1620}\zeta(3)\pi^4, \quad (8)$$

where $\psi_n(x)$ is the POLYGAMMA FUNCTION and $\zeta(x)$ is the RIEMANN ZETA FUNCTION (Plouffe 1998).

Similarly, we have

$$\sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{\binom{2n}{n}} = \tfrac{1}{25}[5 + 4\sqrt{5}\,\mathrm{csch}^{-1}(2)] \quad (9)$$

$$\sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n\binom{2n}{n}} = \tfrac{2}{5}\sqrt{5}\,\mathrm{csch}^{-1}(2) \quad (10)$$

$$\sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n^2\binom{2n}{n}} = 2[\mathrm{csch}^{-1}(2)]^2 \quad (11)$$

$$\sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n^3\binom{2n}{n}} = \tfrac{2}{5}\,\zeta(3) \quad (12)$$

(Le Lionnais 1983, p. 35; Guy 1994, p. 257), where $\zeta(z)$ is the RIEMANN ZETA FUNCTION. These follow from the analogous identity

$$\sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n^k\binom{2n}{n}} = \tfrac{1}{2}{}_{k+1}F_k(\underbrace{1, \ldots, 1}_{k+1}; \tfrac{3}{2}, \underbrace{2, \ldots, 2}_{k-1}; -\tfrac{1}{4}). \quad (13)$$

Erdos and Graham (1980, p. 71) conjectured that the central binomial coefficient $\binom{2n}{n}$ is *never* SQUAREFREE for $n > 4$, and this is sometimes known as the ERDOS SQUAREFREE CONJECTURE. SÁRKOZY'S THEOREM (Sárkozy 1985) provides a partial solution which states that the BINOMIAL COEFFICIENT $\binom{2n}{n}$ is never SQUAREFREE for all sufficiently large $n \geq n_0$ (Vardi 1991). Granville and Ramare (1996) proved that the *only* SQUAREFREE values are $n = 2$ and 4. Sander (1992) subsequently showed that $\binom{2n\pm d}{n}$ are also never SQUAREFREE for sufficiently large n as long as d is not "too big."

Central Difference

The central difference for a function tabulated at equal intervals f_n is defined by

$$\delta(f_n) = \delta_n = \delta_n^1 = f_{n+1/2} - f_{n-1/2}. \quad (1)$$

First and higher order central differences arranged so as to involve integer indices are then given by

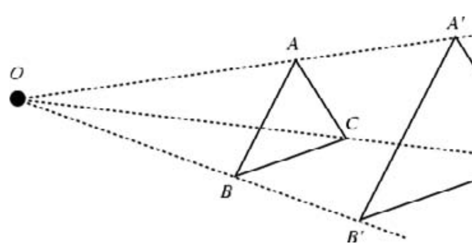
$$\delta_{n+1/2} = \delta_{n+1/2}^1 = f_{n+1} - f_n \quad (2)$$

$$\delta_n^2 = \delta_{n+1/2}^1 - \delta_{n-1/2}^1 = f_{n+1} - 2f_n + f_{n-1} \tag{3}$$

$$\delta_{n+1/2}^3 = \delta_{n+1}^2 - \delta_n^2 = f_{n+2} - 3f_{n+1} + 3f_n - f_{n-1}. \tag{4}$$

Higher order differences may be computed for EVEN and ODD powers,

$$\delta_{n+1/2}^{2k} = \sum_{j=0}^{2k} (-1)^j \binom{2k}{j} f_{n+k-j} \tag{5}$$



$$\delta_{n+1/2}^{2k+1} = \sum_{j=0}^{2k+1} (-1)^j \binom{2k+1}{j} f_{n+k+1-j}. \tag{6}$$

Central Factorial

The central factorials $x^{[k]}$ form an associated SHEFFER SEQUENCE with

$$f(t) = e^{t/2} - e^{-t/2} = 2\sinh(\tfrac{1}{2}t),$$

giving the GENERATING FUNCTION

$$\sum_{k=0}^{\infty} \frac{x^{[k]}}{k!} t^k = e^{2x \sinh^{-1}(t/2)}.$$

The first central factorials are

$$\begin{aligned}
x^{[0]} &= 1 \\
x^{[1]} &= x \\
x^{[2]} &= x^2 \\
x^{[3]} &= \tfrac{1}{4}(4x^3 - x) = -\tfrac{1}{4}(1-2x)x(1+2x) \\

Central Limit Theorem

Let $x_1, x_2, \ldots, x_N$ be a set of N INDEPENDENT random variates and each x_i have an *arbitrary* probability distribution $P(x_1, \ldots, x_N)$ with MEAN μ_i and a finite VARIANCE σ_i^2. Then the normal form variate

$$X_{\text{norm}} \equiv \frac{\sum_{i=1}^N x_i - \sum_{i=1}^N \mu_i}{\sqrt{\sum_{i=1}^N \sigma_i^2}} \tag{1}$$

has a limiting cumulative distribution function which approaches a NORMAL (GAUSSIAN).

Under additional conditions on the distribution of the summand, the probability density itself is also GAUSSIAN (Feller 1971) with MEAN $\mu = 0$ and VARIANCE $\sigma^2 = 1$. If conversion to normal form is not performed, then the variate

$$X \equiv \frac{1}{N} \sum_{i=1}^N x_i \tag{2}$$

is NORMALLY DISTRIBUTED with $\mu_X = \mu_x$ and $\sigma_X = \sigma_x/\sqrt{N}$.

Kallenberg (1997) gives a six-line proof of the central limit theorem. An elementary, but slightly more cumbersome proof of the central limit theorem, consider the INVERSE FOURIER TRANSFORM of $P_X(f)$.

$$\mathscr{F}^{-1}[P_X(f)] \equiv \int_{-\infty}^{\infty} e^{2\pi i f X} P(X)\,dX$$
$$= \int_{-\infty}^{\infty} \sum_{n=0}^{\infty} \frac{(2\pi i f X)^n}{n!} P(X)\,dX$$
$$= \sum_{n=0}^{\infty} \frac{(2\pi i f)^n}{n!} \int_{-\infty}^{\infty} X^n P(X)\,dX$$
$$= \sum_{n=0}^{\infty} \frac{(2\pi i f)^n}{n!} \langle X^n \rangle. \tag{3}$$

Now write

$$\langle X^n \rangle = \langle N^{-n}(x_1 + x_2 + \ldots + x_N)^n \rangle$$
$$= \int_{-\infty}^{\infty} N^{-n}(x_1 + \ldots + x_N)^n P(x_1)\cdots P(x_N)\,dx_1 \cdots dx_N, \tag{4}$$

so we have

$$\mathscr{F}^{-1}[P_X(f)] = \sum_{n=0}^{\infty} \frac{(2\pi i f)^n}{n!} \langle X^n \rangle$$
$$= \sum_{n=0}^{\infty} \frac{(2\pi i f)^n}{n!} \int_{-\infty}^{\infty} N^{-n}(x_1 + \ldots + x_N)^n \times P(x_1)\cdots P(x_N)\,dx_1 \cdots dx_N$$
$$= \int_{-\infty}^{\infty} \sum_{n=0}^{\infty} \left[\frac{2\pi i f(x_1 + \ldots + x_N)}{N}\right]^n \frac{1}{n!} \times P(x_1)\cdots P(x_N)\,dx_1 \cdots dx_N$$
$$= \int_{-\infty}^{\infty} e^{2\pi i f(x_1 + \ldots + x_N)/N} P(x_1)\cdots P(x_N)\,dx_1 \cdots dx_N$$
$$= \left[\int_{-\infty}^{\infty} e^{2\pi i f x_1/N} P(x_1)\,dx_1\right] \times \cdots \times \left[\int_{-\infty}^{\infty} e^{2\pi i f x_N/N} P(x_N)\,dx_N\right]$$
$$= \left[\int_{-\infty}^{\infty} e^{2\pi i f x/N} P(x)\,dx\right]^N$$

$$= \left\{\int_{-\infty}^{\infty} \left[1 + \left(\frac{2\pi i f}{N}\right)x + \frac{1}{2}\left(\frac{2\pi i f}{N}\right)^2 x^2 + \ldots\right] P(x)\,dx\right\}^N$$

$$= \left[\int_{-\infty}^{\infty} P(x)\,dx + \frac{2\pi i f}{N}\int_{-\infty}^{\infty} xP(x)\,dx - \frac{(2\pi f)^2}{2N^2}\int_{-\infty}^{\infty} x^2 P(x)\,dx + \mathcal{O}(N^{-3})\right]^N$$
$$= \left[1 + \frac{2\pi i f}{N}\langle x \rangle - \frac{(2\pi f)^2}{2N^2}\langle x^2 \rangle + \mathcal{O}(N^{-3})\right]^N$$
$$= \exp\left\{N \ln\left[1 + \frac{2\pi i f}{N}\langle x \rangle - \frac{(2\pi f)^2}{2N^2}\langle x^2 \rangle + \mathcal{O}(N^{-3})\right]\right\} \tag{5}$$

Now expand

$$\ln(1+x) = x - \tfrac{1}{2}x^2 + \tfrac{1}{3}x^3 + \ldots, \tag{6}$$

so

$$\mathscr{F}^{-1}[P_X(f)] \approx \exp\left\{N\left[\frac{2\pi i f}{N}\langle x \rangle - \frac{(2\pi f)^2}{2N^2}\langle x^2 \rangle + \frac{1}{2}\frac{(2\pi i f)^2}{N^2}\langle x \rangle^2 + \mathcal{O}(N^{-3})\right]\right\}$$
$$= \exp\left[2\pi i f \langle x \rangle - \frac{(2\pi f)^2(\langle x^2 \rangle - \langle x \rangle^2)}{2N} + \mathcal{O}(N^{-2})\right]$$
$$\approx \exp\left[2\pi i f \mu_x - \frac{(2\pi f)^2 \sigma_x^2}{2N}\right], \tag{7}$$

since

$$\mu_x \equiv \langle x \rangle \tag{8}$$

$$\sigma_x^2 \equiv \langle x^2 \rangle - \langle x \rangle^2. \tag{9}$$

Taking the FOURIER TRANSFORM,

$$P_X \equiv \int_{-\infty}^{\infty} e^{-2\pi i f x} \mathscr{F}^{-1}[P_X(f)]\,df$$
$$= \int_{-\infty}^{\infty} e^{2\pi i f(\mu_x - x) - (2\pi f)^2 \sigma_x^2/2N}\,df. \tag{10}$$

This is OF THE FORM

$$\int_{-\infty}^{\infty} e^{iaf - bf^2}\,df, \tag{11}$$

where $a \equiv 2\pi(\mu_x - x)$ and $b \equiv (2\pi\sigma_x)^2/2N$. But, from Abramowitz and Stegun (1972, p. 302, equation 7.4.6),

$$\int_{-\infty}^{\infty} e^{iaf - bf^2}\,df = e^{-a^2/4b}\sqrt{\frac{\pi}{b}}. \tag{12}$$

Therefore,

$$P_X = \sqrt{\frac{\pi}{\frac{(2\pi\sigma_z)^2}{2N}}} \exp\left\{\frac{-[2\pi(\mu_x - x)]^2}{4\frac{(2\pi\sigma_z)^2}{2N}}\right\}$$

$$= \sqrt{\frac{2\pi N}{4\pi^2\sigma_x^2}} \exp\left[-\frac{4\pi^2(\mu_x - x)^2 2N}{4 \cdot 4\pi^2\sigma_x^2}\right]$$

$$= \frac{\sqrt{N}}{\sigma_x\sqrt{2\pi}} e^{-(\mu_z - x)^2 N/2\sigma_z^2}. \quad (13)$$

But $\mu_X = \mu_x$ and $\mu_X = \mu_x$, so

$$P_X = \frac{1}{\sigma_X\sqrt{2\pi}} e^{-(\mu_X - x)^2/2\sigma_X^2}. \quad (14)$$

The "fuzzy" central limit theorem says that data which are influenced by many small and unrelated random effects are approximately NORMALLY DISTRIBUTED.

Central Moment

A MOMENT μ_n of a probability function $P(x)$ taken about the mean μ,

$$\mu_n = \int (x-\mu)^n P(x)\, dx. \quad (1)$$

The central moments μ_n can be expressed as terms of the RAW MOMENTS μ'_n (i.e., those taken about zero) using the BINOMIAL TRANSFORM

$$\mu_n = \sum_{k=0}^{n} \binom{n}{k} (-1)^{n-k} \mu'_k {\mu'_1}^{n-k}, \quad (2)$$

with $\mu'_0 = 1$ (Papoulis 1986, p. 146). The first few values are therefore

$$\mu_1 = 0 \quad (3)$$

$$\mu_2 = -{\mu'_1}^2 + \mu'_2 \quad (4)$$

$$\mu_3 = 2{\mu'_1}^3 - 3\mu'_1\mu'_2 + \mu'_3 \quad (5)$$

$$\mu_4 = -3{\mu'_1}^4 + 6{\mu'_1}^2\mu'_2 - 4\mu'_1\mu'_3 + \mu'_4 \quad (6)$$

$$\mu_5 = 4{\mu'_1}^5 - 10{\mu'_1}^3\mu'_2 + 10{\mu'_1}^2\mu'_3 - 5\mu'_1\mu'_4 + \mu'_5. \quad (6)$$

Central Tree

CENTERED TREE

Central Trinomial Coefficient

The nth central trinomial coefficient is defined as the coefficient of x_n in the expansion of $(1+x+x^2)^n$. It is also the number of permutations of n symbols, each -1, 0, or 1, which sum to 0. For example, there are seven such permutations of three symbols: $\{-1, 0, 1\}$, $\{-1, 1, 0\}$, $\{0, -1, 1\}$, $\{0, 0, 0\}$, and $\{0, 1, -1\}$, $\{1, -1, 0\}$, $\{1, 0, -1\}$. The first few central binomial coefficients are 1, 3, 7, 19, 51, 141, 393, ... (Sloane's A002426). This sequence cannot be expressed as a fixed number of hypergeometric terms (Petkovsek *et al.* 1996, p. 160). The GENERATING FUNCTION is given by

$$f(x) = \frac{1}{\sqrt{(1+x)(1-3x)}} = 1 + x + 3x^2 + 7x^3 + \ldots.$$

Central Value

CLASS MARK

Centralizer

The centralizer of an element z of a GROUP G is the set of elements of G which commute with z,

$$C_G(z) = \{x \in G,\ xz = zx\}.$$

Likewise, the centralizer of a SUBGROUP H of a GROUP G is the set of elements of G which commute with every element of H,

$$C_G(H) = \{x \in G,\ \forall h \in H,\ xh = hx\}.$$

The centralizer always contains the CENTER of the group and is contained in the corresponding NORMALIZER. In an ABELIAN GROUP, the centralizer is the whole group.

See also ABELIAN GROUP, CENTER (GROUP), GROUP, NORMALIZER, SUBGROUP

Centrally Symmetric Set

CENTROSYMMETRIC SET

Centric Perspective

PERSPECTIVE

Centrode

$$\mathbf{C} \equiv \tau\mathbf{T} + \kappa\mathbf{B},$$

where τ is the TORSION, κ is the CURVATURE, $\mathbf{T}$ is the TANGENT VECTOR, and $\mathbf{B}$ is the BINORMAL VECTOR.

Centroid (Function)

By analogy with the GEOMETRIC CENTROID, the centroid of an arbitrary function $f(x)$ is defined as

$$\langle x \rangle = \frac{\int_{-\infty}^{\infty} x f(x)\,dx}{\int_{-\infty}^{\infty} f(x)\,dx}.$$

References

Bracewell, R. *The Fourier Transform and Its Applications, 3rd ed.* New York: McGraw-Hill, pp. 139–140 and 156, 1999.

Centroid (Geometric)

The CENTER OF MASS of a 2-D planar LAMINA or a 3-D solid. The mass of a LAMINA with surface density function $\sigma(x, y)$ is

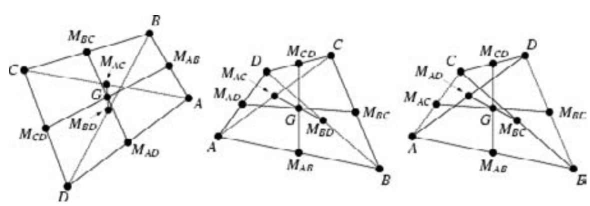
$$M = \iint \sigma(x, y)\,dA, \tag{1}$$

and the coordinates of the centroid (also called the CENTER OF GRAVITY) are

$$\bar{x} = \frac{\iint x\sigma(x, y)\,dA}{M} \tag{2}$$

$$\bar{y} = \frac{\iint y\sigma(x, y)\,dA}{M}. \tag{3}$$

The centroid of a lamina is the point on which it would balance when placed on a needle. The centroid of a solid is the point on which the solid would "balance."



The centroid of a set of n point masses m_i located at positions $\mathbf{x}_i$ is

$$\bar{\mathbf{x}} = \frac{\sum_{i=1}^{n} m_i \mathbf{x}_i}{\sum_{i=1}^{n} m_i}, \tag{4}$$

which, if all masses are equal, simplifies to

$$\bar{\mathbf{x}} = \frac{\sum_{i=1}^{n} \mathbf{x}_i}{n}. \tag{5}$$

The centroid of n point masses also gives the location at which a school should be built in order to minimize the distance travelled by children from n cities, located at the positions of the masses, and with m_i equal to the number of students from city i (Steinhaus 1983, pp. 113–116).

The centroid of the vertices of a quadrilateral occurs at the point of intersection of the BIMEDIANS (i.e., the lines $M_{AB}M_{CD}$ and $M_{AD}M_{BC}$ joining pairs of opposite MIDPOINTS) (Honsberger 1995, pp. 36–37). In addition, it is the MIDPOINT of the line $M_{AC}M_{BD}$ connecting the midpoints of the diagonals AC and BD (Honsberger 1995, pp. 39–40).

Given an arbitrary HEXAGON, connecting the centroids of each consecutive three sides gives the so-called CENTROID HEXAGON, a hexagon with equal and

parallel sides (Wells 1991).

The centroids of several common laminas along the nonsymmetrical axis are summarized in the following table.

Figure	$\bar{y}$
PARABOLIC SEGMENT	$\frac{2}{5}h$
SEMICIRCLE	$\frac{4r}{3\pi}$

In 3-D, the mass of a solid with density function $\rho(x, y, z)$ is

$$M = \iiint \rho(x, y, z)\, dV, \tag{6}$$

and the coordinates of the center of mass are

$$\bar{x} = \frac{\iiint x\rho(x, y, z)\, dV}{M} \tag{7}$$

$$\bar{y} = \frac{\iiint y\rho(x, y, z)\, dV}{M} \tag{8}$$

$$\bar{z} = \frac{\iiint z\rho(x, y, z)\, dV}{M}. \tag{9}$$

Centroid (Orthocentric System)

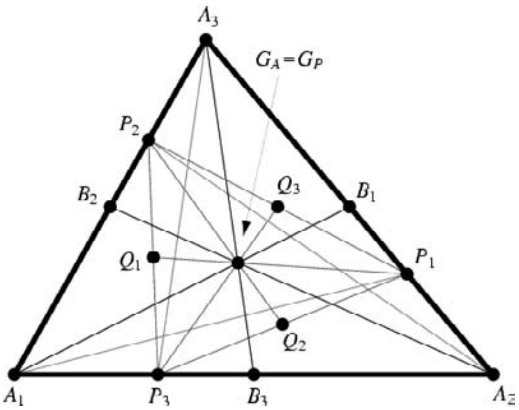
The centroid of the four points constituting an ORTHOCENTRIC SYSTEM is the center of the common NINE-POINT CIRCLE (Johnson 1929, p. 249). This fact automatically guarantees that the centroid of the INCENTER and EXCENTERS of a TRIANGLE is located at the CIRCUMCENTER.

References

Johnson, R. A. *Modern Geometry: An Elementary Treatise on the Geometry of the Triangle and the Circle.* Boston, MA: Houghton Mifflin, 1929.

Centroid (Triangle)

The CENTROID (CENTER OF MASS) of the VERTICES of a TRIANGLE is the point G (sometimes also denoted M) which is also the intersection of the TRIANGLE'S three MEDIANS (Johnson 1929, p. 249; Wells 1991, p. 150). The point is therefore sometimes called the median point. The centroid is always in the interior of the TRIANGLE. It has TRILINEAR COORDINATES

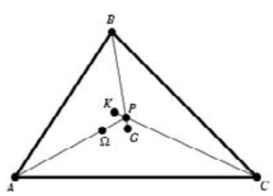


$$\frac{1}{a} : \frac{1}{b} : \frac{1}{c}, \tag{1}$$

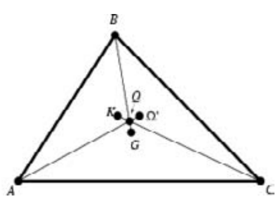
or

$$\csc A : \csc B : \csc C, \tag{2}$$

and homogeneous BARYCENTRIC COORDINATES



(1, 1, 1).



If the sides of a TRIANGLE $\Delta A_1A_2A_3$ are divided by points P_1, P_2, and P_3 so that

$$\frac{\overline{A_2P_1}}{\overline{P_1A_3}} = \frac{\overline{A_3P_2}}{\overline{P_2A_1}} = \frac{\overline{A_1P_3}}{\overline{P_3A_2}} = \frac{p}{q}, \tag{3}$$

then the centroid of the TRIANGLE $\Delta P_1P_2P_3$ is M, the centroid of the original triangle $\Delta A_1A_2A_3$ (Johnson 1929, p. 250).

One BROCARD LINE, MEDIAN, and SYMMEDIAN (out of the three of each) are CONCURRENT, with $A\Omega$, CK, and BG meeting at a point, where Ω is the first BROCARD POINT and K is the SYMMEDIAN POINT. Similarly, $A\Omega'$, BG, and CK, where Ω' is the second BROCARD POINT, meet at a point which is the ISOGONAL CONJUGATE of the first (Johnson 1929, pp. 268–269).

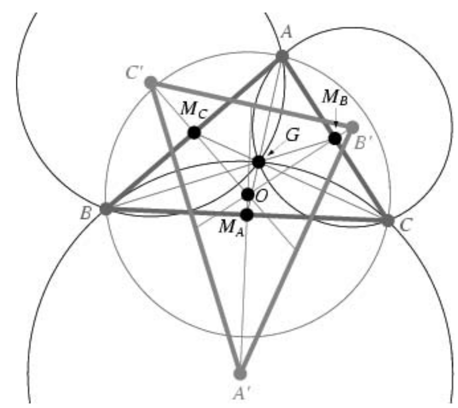
Pick an interior point X. The TRIANGLES BXC, CXA, and AXB have equal areas IFF X corresponds to the centroid. The centroid is located one third of the way from each VERTEX to the MIDPOINT of the opposite side. Each median divides the triangle into two equal areas; all the medians together divide it into six equal parts, and the lines from the MEDIAN POINT to the VERTICES divide the whole into three equivalent TRIANGLES. In general, for any line in the plane of a TRIANGLE ABC,

$$d = \tfrac{1}{3}(d_A + d_B + d_C), \tag{4}$$

where d, d_A, d_B, and d_C are the distances from the centroid and VERTICES to the line.

A TRIANGLE will balance at the centroid, and along any line passing through the centroid. The TRILINEAR POLAR of the centroid is called the LEMOINE AXIS. The PERPENDICULARS from the centroid are proportional to s_i^{-1},

$$a_1p_2 = a_2p_2 = a_3p_3 = \tfrac{2}{3}\Delta, \tag{5}$$



where Δ is the AREA of the TRIANGLE. Let P be an arbitrary point, the VERTICES be A_1, A_2, and A_3, and the centroid G. Then

$$\overline{PA_1}^2 + \overline{PA_2}^2 + \overline{PA_3}^2 = \overline{GA_1}^2 + \overline{GA_2}^2 + \overline{GA_3}^2 + 3\overline{PG}^2. \tag{6}$$

If O is the CIRCUMCENTER of the triangle's centroid, then

$$\overline{OG}^2 = R^2 - \tfrac{1}{9}(a^2 + b^2 + c^2). \tag{7}$$

The centroid lies on the EULER LINE and NAGEL LINE. The centroid of the PERIMETER of a TRIANGLE is the triangle's SPIEKER CENTER (Johnson 1929, p. 249). The SYMMEDIAN POINT of a triangle is the centroid of its PEDAL TRIANGLE (Honsberger 1995, pp. 72–74).

Given a triangle ΔABC, construct circles through each pair of vertices which also pass through the CENTROID G. The TRIANGLE $\Delta A'B'C'$ determined by the center of these circles then satisfies a number of interesting properties. The first is that the CIRCUMCIRCLE O and CENTROID G of ΔABC are, respectively, the CENTROID G' and SYMMEDIAN POINT K' of the triangle $\Delta A'B'C'$ (Honsberger 1995, p. 77). In addition, the MEDIANS of ΔABC and $\Delta A'B'C$ intersect in the midpoints of the sides of ΔABC.

Ceva's Theorem

Given a TRIANGLE with VERTICES A, B, and C and points along the sides D, E, and F, a NECESSARY and SUFFICIENT condition for the CEVIANS AD, BE, and CF to be CONCURRENT (intersect in a single point) is that

$$BD \cdot CE \cdot AF = DC \cdot EA \cdot FB. \qquad (1)$$

This theorem was first published by Giovanni Cevian 1678.

Let $P = [V_1, \ldots, V_n]$ be an arbitrary n-gon, C a given point, and k a POSITIVE INTEGER such that $1 \leq k \leq n/2$. For $i = 1, ..., n$, let W_i be the intersection of the lines CV_i and $V_{i-k}V_{i+k}$, then

$$\prod_{i=1}^{n} \left[\frac{V_{i-k}W_i}{W_i V_{i+k}}\right] = 1. \qquad (2)$$

Here, $AB \| CD$ and

$$\left[\frac{AB}{CD}\right] \qquad (3)$$

is the RATIO of the lengths $[A, B]$ and $[C, D]$ with a plus or minus sign depending on whether these segments have the same or opposite directions (Grünbaum and Shepard 1995).

Another form of the theorem is that three CONCURRENT lines from the VERTICES of a TRIANGLE divide the opposite sides in such fashion that the product of three nonadjacent segments equals the product of the other three (Johnson 1929, p. 147).

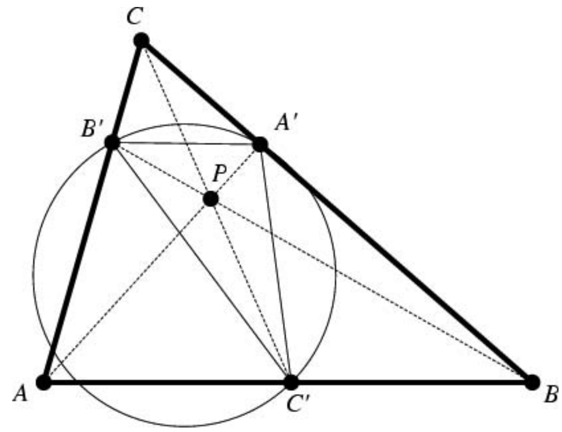
Cevian

A line segment which joins a VERTEX of a TRIANGLE with a point on the opposite side (or its extension). In the above figure,

$$s = \frac{b \sin \alpha'}{\sin(\gamma + \alpha')}.$$

The condition for Cevians from the three sides of a TRIANGLE to CONCUR is known as CEVA'S THEOREM. If AD, BE, and CF are cevians of a TRIANGLE ΔABC through an arbitrary point P inside ΔABC, then the ratios

$$\frac{AP}{PD}, \frac{BP}{PE}, \frac{CP}{PF}$$



into which P divides the Cevians have a sum ≥ 6 and a product ≥ 8 (Ramler 1958; Honsberger 1995, pp. 138–141).

Cevian Triangle

Given a point P and a TRIANGLE ΔABC, the Cevian triangle $\Delta A'B'C'$ is defined as the triangle composed of the endpoints of the CEVIANS though P. If the point P has TRILINEAR COORDINATES $\alpha:\beta:\gamma$, then the Cevian triangle has VERTICES $0:\beta:\gamma$, $\alpha:0:\gamma$, and $\alpha:\beta:0$. If $A'B'C'$ is the CEVIAN TRIANGLE of X and $A''B''C''$ is the ANTICEVIAN TRIANGLE, then X and A'' are HARMO-

NIC CONJUGATE POINTS with respect to A and A'.

If $\Delta A'B'C'$ is the Cevian triangle of ΔABC, then the triangle $\Delta A''B''C''$ obtained by reflecting A', B', and C' across the midpoints of their sides is also a Cevian triangle of ΔABC (Honsberger 1995, p. 141; left figure). Furthermore, if the CEVIAN CIRCLE crosses the sides of ΔABC in three points A'', B'', and C'', then $\Delta A''B''C''$ is also a Cevian triangle of ΔABC (Honsberger 1995, pp. 141–142; right figure).

CG

Given a GROUP G, the algebra $\mathbb{C}G$ is a VECTOR SPACE

$$\mathbb{C}G = \left\{\sum a_i g_i | a_i \in \mathbb{C},\ g_i \in G\right\}$$

of finite sums of elements of G, with multiplication defined by $g \cdot h = gh$, the group operation. It is an example of a GROUP RING.

For example, when the group is the SYMMETRIC GROUP on three letters, S_3, the GROUP RING $\mathbb{C}S_3$ is a six-dimensional algebra. An example of the product of elements is

$$(3\{1,\ 3,\ 2\} + i\{1,\ 2,\ 3\})(-2\{2,\ 1,\ 3\} + \{3,\ 2,\ 1\})$$
$$= -6\{2,\ 3,\ 1\} - 2i\{2,\ 1,\ 3\} + i\{3,\ 2,\ 1\} + 3\{3,\ 1,\ 2\}.$$

MODULES over $\mathbb{C}G$ correspond to complex REPRESENTATIONS of G. When G is a FINITE GROUP then $\mathbb{C}G$ is a finite-dimensional algebra.

Ch

HYPERBOLIC COSINE

Chain

Let P be a finite PARTIALLY ORDERED SET. A chain in P is a set of pairwise comparable elements (i.e., a TOTALLY ORDERED subset). The LENGTH of P is the maximum CARDINALITY of a chain in P. For a PARTIAL ORDER, the size of the longest chain is called the LENGTH.

See also ADDITION CHAIN, ANTICHAIN, BRAUER CHAIN, CHAIN (GRAPH), CHAIN OF CIRCLES, DILWORTH'S LEMMA, HANSEN CHAIN, LENGTH (PARTIAL ORDER), PAPPUS CHAIN, PARTIAL ORDER

Chain (Graph)

A chain of a GRAPH is a SEQUENCE $\{x_1,\ x_2,\ \ldots,\ x_n\}$ such that $(x_1,\ x_2)$, $(x_2,\ x_3)$, ..., $(x_{n-1},\ x_n)$ are EDGES of the GRAPH.

See also GRAPH

Chain Complex

A chain complex is a sequence of maps

$$\cdots \xrightarrow{\partial_{i+1}} C_i \xrightarrow{\partial_i} C_{i-1} \xrightarrow{\partial_{i-1}} \cdots, \qquad (1)$$

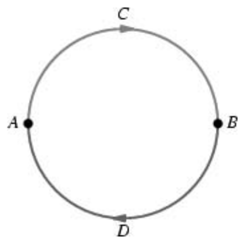
where the spaces C_i may be GROUPS or MODULES. The maps must satisfy $\partial_{i-1} \circ \partial_i = 0$. Making the domain implicitly understood, the maps are denoted by ∂, called the BOUNDARY OPERATOR or the differential. Chain complexes are an algebraic tool for computing or defining HOMOLOGY and have a variety of applications. A COCHAIN COMPLEX is used in the case of COHOMOLOGY.

Elements of C_p are called CHAINS. For each p, the kernel of $\partial_p : C_p \to C_{p-1}$ is called the group of cycles,

$$Z_p = \{c \in C_p : \partial(c) = 0\}. \qquad (2)$$

The letter Z is short for the German word for cycle, "Zyklus." The image $\partial(C_{p+1})$ is contained in the group of cycles because $\partial \circ \partial = 0$. It is called the group of boundaries.

$$B_p = \{c \in C_p : \text{there exists } b \in C_{p+1} \text{ such that } \partial(b) = c\}. \qquad (3)$$



The quotients $H_p = Z_p / B_p$ are the HOMOLOGY GROUPS of the chain.

For example, the sequence

$$\cdots \xrightarrow{\times 4} \mathbb{Z}/8\mathbb{Z} \xrightarrow{\times 4} \mathbb{Z}/8\mathbb{Z} \xrightarrow{\times 4} \cdots, \qquad (4)$$

where every space is $\mathbb{Z}/8\mathbb{Z}$ and each map is given by multiplication by 4 is a chain complex. The cycles at each stage are $Z_p = \{0,\ 2,\ 4,\ 6\}$ and the boundaries are $B_p = \{0,\ 4\}$. So the homology at each stage is the group of two elements $\mathbb{Z}/2\mathbb{Z}$. A simpler example is given by a LINEAR TRANSFORMATION $\alpha : V \to W$, which can be extended to a chain complex by the zero vector

space and the ZERO MAP. Then the nontrivial homology groups are ker α and $W/\text{im}(\alpha)$.

The terminology of chain complexes comes from the calculation for HOMOLOGY of geometric objects in a TOPOLOGICAL SPACE, like a MANIFOLD. For example, the figure above is the circle as a SIMPLICIAL COMPLEX. Let A and B denote the points, and C and D denote the oriented segments, which are the chains. The boundary of C is $B-A$, and the boundary of D is $A-B$.

The group C_1 is the FREE ABELIAN GROUP $\langle C, D\rangle$ and the group C_0 is the FREE ABELIAN GROUP $\langle A, B\rangle$. The BOUNDARY OPERATOR is

$$\begin{aligned}\partial(nC+mD) &= n(B-A)+m(A-B)\\ &= (m-n)A+(n-m)B. \quad (5)\end{aligned}$$

The other groups C_p are the TRIVIAL GROUP, and the other maps are the ZERO MAP. Then Z_1 is generated by $C+D$ and B_1 is the trivial subgroup. So H_1 is the rank one FREE ABELIAN GROUP isomorphic to $\mathbb{Z}$. The zero-dimensional case is slightly more interesting. Every element of C_0 has no boundary and so is in Z_0 while the boundaries B_0 are generated by $A-B$. Hence, $H_0=Z_0/B_0$ is also isomorphic to $\mathbb{Z}$. Note that the result is not affected by how the circle is cut into pieces, or by how many cuts are used.

Chain Equivalence

Chain equivalences give an EQUIVALENCE RELATION on the space of CHAIN HOMOMORPHISMS. Two CHAIN COMPLEXES are chain equivalent if there are chain maps $\phi: C_* \to D_*$ and $\gamma: D_* \to C_*$ such that $\phi\circ\gamma$ is CHAIN HOMOTOPIC to the identity on D_* and $\gamma\circ\phi$ is CHAIN HOMOTOPIC to the identity on C_*.

Chain Fraction

CONTINUED FRACTION

Chain Homomorphism

Also called a chain map. Given two CHAIN COMPLEXES C_* and D_*, a chain homomorphism is given by homomorphisms $\alpha_i: C_i \to D_i$ such that

$$\alpha\circ\partial_C = \partial_D\circ\alpha,$$

where ∂_C and ∂_D are the BOUNDARY OPERATORS.

See also CHAIN COMPLEX, CHAIN EQUIVALENCE, CHAIN HOMOTOPY, HOMOMORPHISM (MODULE)

Chain Homotopy

Suppose $\alpha: C_* \to D_*$ and $\beta: C_* \to D_*$ are two CHAIN HOMOMORPHISMS. Then a chain homotopy is given by a sequence of maps

$$\delta_p: C_p \to D_{p+1}$$

such that

$$\partial_D\circ\delta+\delta\circ\partial_C=\alpha-\beta,$$

where ∂ denotes the BOUNDARY OPERATOR.

Chain Map

CHAIN HOMOMORPHISM

Chain of Circles

A sequence of circles which closes (such as a STEINER CHAIN or the circles inscribed in the ARBELOS) is called a chain.

See also ARBELOS, COXETER'S LOXODROMIC SEQUENCE OF TANGENT CIRCLES, NINE CIRCLES THEOREM, PAPPUS CHAIN, SEVEN CIRCLES THEOREM, SIX CIRCLES THEOREM, STEINER CHAIN, STEINER'S PORISM

References

Evelyn, C. J. A.; Money-Coutts, G. B.; and Tyrrell, J. A. "Chains of Circles." Ch. 3 in *The Seven Circles Theorem and Other New Theorems.* London: Stacey International, pp. 31–68, 1974.

Chain Rule

If $g(x)$ is DIFFERENTIABLE at the point x and $f(x)$ is DIFFERENTIABLE at the point $g(x)$, then $f \circ g$ is DIFFERENTIABLE at x. Furthermore, let $y = f(g(x))$ and $u = g(x)$, then

$$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx}. \tag{1}$$

There are a number of related results which also go under the name of "chain rules." For example, if $z = f(x, y)$, $x = g(t)$, and $y = h(t)$, then

$$\frac{dz}{dt} = \frac{\partial z}{\partial x}\frac{dx}{dt} + \frac{\partial z}{\partial y}\frac{dy}{dt}. \tag{2}$$

The "general" chain rule applies to two sets of functions

$$\begin{aligned} y_1 &= f_1(u_1, \ldots, u_p) \\ &\vdots \\ y_m &= f_m(u_1, \ldots, u_p) \end{aligned} \tag{3}$$

and

$$\begin{aligned} u_1 &= g_1(x_1, \ldots, x_n) \\ &\vdots \\ u_p &= g_p(x_1, \ldots, x_n). \end{aligned} \tag{4}$$

Defining the $m \times n$ JACOBI MATRIX by

$$\left(\frac{\partial y_i}{\partial x_j}\right) = \begin{bmatrix} \frac{\partial y_1}{\partial x_1} & \frac{\partial y_1}{\partial x_2} & \cdots & \frac{\partial y_1}{\partial x_n} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial y_m}{\partial x_1} & \frac{\partial y_m}{\partial x_2} & \cdots & \frac{\partial y_m}{\partial x_n} \end{bmatrix}, \tag{5}$$

and similarly for $(\partial y_i/\partial u_j)$ and $(\partial u_i/\partial x_j)$ then gives

$$\left(\frac{\partial y_i}{\partial x_j}\right) = \left(\frac{\partial y_i}{\partial u_j}\right)\left(\frac{\partial u_i}{\partial x_j}\right). \tag{6}$$

In differential form, this becomes

$$dy_1 = \left(\frac{\partial y_1}{\partial u_1}\frac{\partial u_1}{\partial x_1} + \ldots + \frac{\partial y_1}{\partial u_p}\frac{\partial u_p}{\partial x_1}\right) dx_1 + \left(\frac{\partial y_1}{\partial u_1}\frac{\partial u_1}{\partial x_2} + \ldots + \frac{\partial y_1}{\partial u_p}\frac{\partial u_p}{\partial x_2}\right) dx_2 + \ldots \tag{7}$$

(Kaplan 1984).

CHAITIN'S CONSTANT

Champernowne Constant

Champernowne's constant 0.1234567891011... (Sloane's A033307) is the number obtained by concatenating the POSITIVE INTEGERS and interpreting them as decimal digits to the right of a decimal point. It is NORMAL in base 10. In 1961, Mahler showed it to also be TRANSCENDENTAL.

The first few terms in the CONTINUED FRACTION of the Champernowne constant are 0, 8, 9, 1, 149083, 1, 1, 1, 4, 1, 1, 1, 3, 4, 1, 1, 1, 15,

$$4575401113910310764836466282429561185996039 39\ldots$$

$$7104575550006620043930902626592563149379532 07\ldots$$

$$7471286563138641209375503552094607183089984 57\ldots$$

$$58014698631488335921417830109 87,$$

6, 1, 1, 21, 1, 9, 1, 1, 2, 3, 1, 7, 2, 1, 83, 1, 156, 4, 58, 8, 54, ... (Sloane's A030167). The next term of the CONTINUED FRACTION is huge, having 2504 digits.

In fact, the coefficients eventually become unbounded, making the continued fraction difficult to calculate for too many more terms. Large terms greater than 10^5 occur at positions 5, 19, 41, 102, 163, 247, 358, 460, ... and have 6, 166, 2504, 140, 33102, 109, 2468, 136, ... digits, respectively (Plouffe). The 527th partial quotient of the continued fraction expansion has 411,100 decimal digits and the 1709th partial quotient has 4,911,098 decimal digits, as computed using *Mathematica* 4.0. This result was obtained by Mark Sofroniou and Giulia Spaletta and presented at the conference on Foundations of Computational Mathematics in Oxford, UK, July 1999.

Interestingly, the COPELAND-ERDOS CONSTANT, which is the decimal number obtained by concatenating the PRIMES (instead of all the positive integers), has a well-behaved CONTINUED FRACTION that does not show the "large term" phenomenon.

Change of Variables Theorem

A theorem which effectively describes how lengths, areas, volumes, and generalized n-dimensional volumes (CONTENTS) are distorted by DIFFERENTIABLE FUNCTIONS. In particular, the change of variables theorem reduces the whole problem of figuring out the distortion of the content to understanding the infinitesimal distortion, i.e., the distortion of the DERIVATIVE (a linear MAP), which is given by the linear MAP's DETERMINANT. So $f: \mathbb{R}^n \to \mathbb{R}^n$ is an AREA-PRESERVING linear MAP IFF $|\det(f)|=1$, and in more generality, if S is any subset of $\mathbb{R}^n$, the CONTENT of its image is given by $|\det(f)|$ times the CONTENT of the original. The change of variables theorem takes this infinitesimal knowledge, and applies CALCULUS by breaking up the DOMAIN into small pieces and adds up the change in AREA, bit by bit.

The change of variable formula persists to the generality of DIFFERENTIAL FORMS on MANIFOLDS, giving the formula

$$\int_M (f^*\omega) = \int_W (\omega) \tag{1}$$

under the conditions that M and W are compact connected oriented MANIFOLDS with nonempty boundaries, $f: M \to W$ is a smooth map which is an orientation-preserving DIFFEOMORPHISM of the boundaries.

In 1-D, the explicit statement of the theorem for f a continuous function of y is

$$\int_s f(\phi(x)) \frac{d\phi}{dx}\, dx = \int_T f(y)\, dy, \tag{2}$$

where $y=\phi(x)$ is a differential mapping on the interval $[c, d]$ and T is the interval $[a, b]$ with $\phi(c)=a$ and $\phi(d)=b$ (Lax 1999). In 2-D, the explicit statement of the theorem is

$$\int_R f(x, y)\,dx\,dy = \int_{R^*} f[x(u, v), y(u, v)] \left|\frac{\partial(x, y)}{\partial(u, v)}\right| du\,dv$$

and in 3-D, it is

$$\int_R f(x, y, z)\,dx\,dy\,dz = \int_{R^*} f[x(u, v, w), y(u, v, w), z(u, v, w)] \times \left|\frac{\partial(x, y, z)}{\partial(u, v, w)}\right| du\,dv\,dw, \tag{3}$$

where $R=f(R^*)$ is the image of the original region R^*,

$$\left|\frac{\partial(x, y, z)}{\partial(u, v, w)}\right| \tag{4}$$

is the JACOBIAN, and f is a global orientation-preserving DIFFEOMORPHISM of R and R^* (which are open subsets of $\mathbb{R}^n$).

The change of variables theorem is a simple consequence of the CURL THEOREM and a little DE RHAM COHOMOLOGY. The generalization to n-D requires no additional assumptions other than the regularity conditions on the boundary.

Chaos

A DYNAMICAL SYSTEM is chaotic if it

1. Has a DENSE collection of points with periodic orbits,
2. Is sensitive to the initial condition of the system (so that initially nearby points can evolve quickly into very different states), and
3. Is TOPOLOGICALLY TRANSITIVE.

Chaotic systems exhibit irregular, unpredictable behavior (the BUTTERFLY EFFECT). The boundary between linear and chaotic behavior is often characterized by PERIOD DOUBLING, followed by quadrupling, etc., although other routes to chaos are also possible (Abarbanel *et al.* 1993; Hilborn 1994; Strogatz 1994, pp. 363–365).

An example of a simple physical system which displays chaotic behavior is the motion of a magnetic pendulum over a plane containing two or more attractive magnets. The magnet over which the pendulum ultimately comes to rest (due to frictional damping) is highly dependent on the starting position and velocity of the pendulum (Dickau). Another such system is a double pendulum (a pendulum with another pendulum attached to its end).

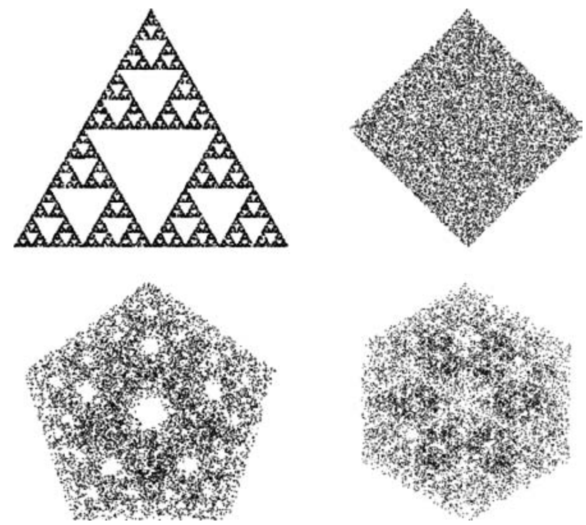
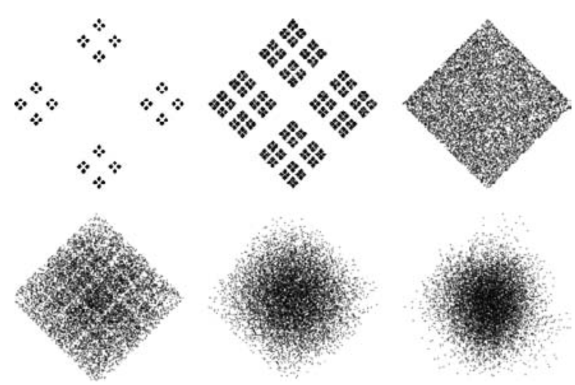
Chaos Game



Pick a point at random inside a regular n-gon. Then draw the next point a fraction r of the distance between it and a VERTEX picked at random. Continue the process (after throwing out the first few points). The result of this "chaos game" is sometimes, but not always, a FRACTAL. The case $(n, r) = (4, 1/2)$ gives the interior of a SQUARE with all points visited with equal probability.



(3, 1/2) (5, 1/3)

(5, 3/8) (6, 1/3)

The above plots show the chaos game for 10,000 points in the regular 3-, 4-, 5-, and 6-gons with $r = 1/2$.

The above plots show the chaos game for 10,000 points in the square with $r = 0.25$, 0.4, 0.5, 0.6, 0.75, and 0.9.

Character (Group)

The GROUP THEORETICAL term for what is known to physicists, by way of its connection with matrix TRACES, as the trace. The powerful GROUP ORTHOGONALITY THEOREM gives a number of important properties about the structures of GROUPS, many of which are most easily expressed in terms of characters. In essence, group characters can be thought of as the TRACES of a special set of matrices (a so-called IRREDUCIBLE REPRESENTATION) used to represent group elements and whose multiplication corresponds to the multiplication table of the group. The explicit construction of a set of characters (CHARACTER TABLE) is illustrated for the FINITE GROUP $D3$.

All members of the same CONJUGACY CLASS in the same representation have the same character. Members of other CONJUGACY CLASSES may also have the same character, however. An (abstract) GROUP can be uniquely identified by a listing of the characters of its various representations, known as a CHARACTER TABLE. Some of the SCHÖNFLIES SYMBOLS denote different sets of symmetry operations but correspond to the same abstract GROUP and so have the same CHARACTER TABLES.

See also CHARACTER TABLE, CONJUGACY CLASS, GROUP ORTHOGONALITY THEOREM, TRACE (MATRIX)

Character (Number Theory)

A number theoretic function $\chi_k(n)$ for POSITIVE integral n is a character modulo k if

$$\chi_k(1) = 1$$

$$\chi_k(n) = \chi_k(n+k)$$

$$\chi_k(m)\chi_k(n) = \chi_k(mn)$$

for all m, n, and

$$\chi_k(n) = 0$$

if $(k, n) \neq 1$. χ_k can only assume values which are $\phi(k)$ ROOTS OF UNITY, where ϕ is the TOTIENT FUNCTION.

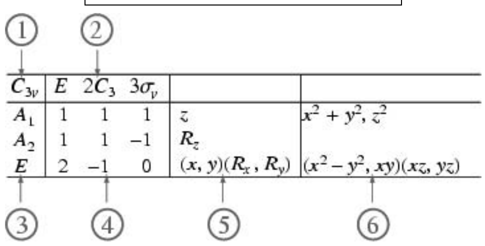
See also DIRICHLET L-SERIES, MULTIPLICATIVE CHARACTER, PRIMITIVE CHARACTER

Character Table

A FINITE GROUP G has a finite number of CONJUGACY CLASSES and a finite number of distinct IRREDUCIBLE REPRESENTATIONS. The CHARACTER of a REPRESENTATION is constant on a CONJUGACY CLASS. Hence, the values of the characters can be written as an array, known as a character table. Typically, the rows are given by the IRREDUCIBLE REPRESENTATIONS and the columns are given the CONJUGACY CLASSES. A character table contains enough information to uniquely identify a given abstract group and distinguish it from others.

For example, the SYMMETRIC GROUP on three letters S_3 has three CONJUGACY CLASSES, represented by the PERMUTATIONS $\{1, 2, 3\}$, $\{2, 1, 3\}$, and $\{2, 3, 1\}$. It also has three IRREDUCIBLE REPRESENTATIONS; two are one-dimensional and the third is two-dimensional:

1. The TRIVIAL REPRESENTATION $\phi_1(g)(\alpha) = \alpha$.
2. The ALTERNATING REPRESENTATION, given by the signature of the PERMUTATION, $\phi_2(g)(\alpha) = \operatorname{sgn}(g)\alpha$.
3. The STANDARD REPRESENTATION on $V = \{(z_1, z_2, z_3) : \Sigma z_i = 0\}$ with $\phi_3(\{a, b, c\})(z_1, z_2, z_3) = (z_a, z_b, z_c)$.



The STANDARD REPRESENTATION can be described on $\mathbb{C}^2$ via the matrices

$$\tilde{\phi}_3(\{2, 1, 3\}) = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$$

$$\tilde{\phi}_3(\{2, 3, 1\}) = \begin{bmatrix} 0 & -1 \\ 1 & -1 \end{bmatrix},$$

and hence the CHARACTER of the first matrix is 0 and that of the second is -1. The CHARACTER of the identity is always the dimension of the VECTOR SPACE. The trace of the alternating representation is just the SIGNATURE of the PERMUTATION. Consequently, the character table for S_3 is shown below.

	1	2	3
S_3	e	(12)	(123)
trivial	1	1	1
alternating	1	-1	1
standard	2	0	-1

Chemists and physicists use a special convention for representing character tables which is applied especially to the so-called POINT GROUPS, which are the 32 finite symmetry groups possible in a lattice. In the example above, the numbered regions contain the following contents (Cotton 1990 pp. 90–92).

1. The symbol used to represent the group in question (in this case C_{3v}).
2. The CONJUGACY CLASSES, indicated by number and symbol, where the sum of the coefficients gives the ORDER of the group.
3. MULLIKEN SYMBOLS, one for each IRREDUCIBLE REPRESENTATION.
4. An array of the CHARACTERS of the IRREDUCIBLE REPRESENTATION of the group, with one column for each CONJUGACY CLASS, and one row for each IRREDUCIBLE REPRESENTATION.
5. Combinations of the symbols x, y, z, R_x, R_y, and R_z, the first three of which represent the coordinates x, y, and z, and the last three of which stand for rotations about these axes. These are related to transformation properties and basis representations of the group.
6. All square and binary products of coordinates according to their transformation properties.

The character tables for many of the POINT GROUPS are reproduced below using this notation.

Characteristic (Euler)

Euler Characteristic

Characteristic (Field)

For a field K with multiplicative identity 1, consider the numbers $2=1+1$, $3=1+1+1$, $4=1+1+1+1$, etc. Either these numbers are all different, in which case we say that K has characteristic 0, or two of them will be equal. In the latter case, it is straightforward to show that, for some number p, we have

$$\underbrace{1+1+\ldots+1}_{p \text{ times}}=0.$$

If p is chosen to be as small as possible, then p will be a prime, and we say that K has characteristic p. The characteristic of a field K is sometimes denoted ch(K).

The fields $\mathbb{Q}$ (rationals), $\mathbb{R}$ (reals), $\mathbb{C}$ (complex numbers), and the p-adic numbers $\mathbb{Q}_p$ have characteristic 0. For p a prime, the finite field GF(p^n) has characteristic p.

If H is a subfield of K, then H and K have the same characteristic.

Characteristic (Partial Differential Equation)

Paths in a 2-D plane used to transform partial differential equations into systems of ordinary differential equations. They were invented by Riemann. For an example of the use of characteristics, consider the equation

$$u_1 - 6uu_x = 0.$$

Now let $u(s)=u(x(s), t(s))$. Since

$$\frac{du}{ds}=\frac{dx}{ds}\,u_x+\frac{dt}{ds}\,u_t,$$

it follows that $dt/ds=1$, $dx/ds=-6u$, and $du/ds=0$. Integrating gives $t(s)=s$, $x(s)=-6su_0(x)$, and $u(s)=u_0(x)$, where the constants of integration are 0 and $u_0(x)=u(x,0)$.

Characteristic (Real Number)

For a REAL NUMBER x, $\lfloor x \rfloor = \text{int}(x)$ is called the characteristic, where $\lfloor x \rfloor$ is the FLOOR FUNCTION.

See also MANTISSA, SCIENTIFIC NOTATION

Characteristic Class

Characteristic classes are COHOMOLOGY classes in the BASE SPACE of a VECTOR BUNDLE, defined through OBSTRUCTION theory, which are (perhaps partial) obstructions to the existence of k everywhere linearly independent vector FIELDS on the VECTOR BUNDLE. The most common examples of characteristic classes are the CHERN, PONTRYAGIN, and STIEFEL-WHITNEY CLASSES.

Characteristic Equation

The equation which is solved to find a matrix's EIGENVALUES, also called the characteristic polynomial. For a general $k \times k$ MATRIX M, the characteristic equation in variable t is defined by

$$\det(\mathsf{M} - t\mathsf{I}) = 0, \tag{1}$$

where I is the IDENTITY MATRIX and $\det(\mathsf{A})$ is the DETERMINANT of the MATRIX A. Writing M out explicitly gives

$$\mathsf{M} \equiv \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1k} \\ a_{21} & a_{22} & \cdots & a_{2k} \\ \vdots & \vdots & \ddots & \vdots \\ a_{k1} & a_{k2} & \cdots & a_{kk} \end{bmatrix}, \tag{2}$$

so the characteristic equation is given by

$$\begin{vmatrix} a_{11} - t & a_{12} & \cdots & a_{1k} \\ a_{21} & a_{22} - t & \cdots & a_{2k} \\ \vdots & \vdots & \ddots & \vdots \\ a_{k1} & a_{k2} & \cdots & a_{kk} - t \end{vmatrix} = 0 \tag{3}$$

The solutions t of the characteristic equation are called EIGENVALUES, and are extremely important in the analysis of many problems in mathematics and physics.

References

Gradshteyn, I. S. and Ryzhik, I. M. *Tables of Integrals, Series, and Products, 6th ed.* San Diego, CA: Academic Press, pp. 1117–1119, 2000.

Characteristic Factor

A characteristic factor is a factor in a particular factorization of the TOTIENT FUNCTION $\phi(n)$ such that the product of characteristic factors gives the representation of a corresponding abstract GROUP as a GROUP DIRECT PRODUCT. By computing the characteristic factors, any ABELIAN GROUP can be expressed as a GROUP DIRECT PRODUCT of CYCLIC SUBGROUPS, for example, the FINITE GROUP $Z_2 \otimes Z_4$ or $Z_2 \otimes Z_2 \otimes Z_2$. There is a simple algorithm for determining the characteristic factors of MODULO MULTIPLICATION GROUPS.

See also CYCLIC GROUP, GROUP DIRECT PRODUCT, MODULO MULTIPLICATION GROUP, TOTIENT FUNCTION

References

Shanks, D. *Solved and Unsolved Problems in Number Theory, 4th ed.* New York: Chelsea, p. 94, 1993.

Characteristic Function (Probability)

The characteristic function $\phi(t)$ is defined as the FOURIER TRANSFORM of the PROBABILITY DENSITY FUNCTION *using* FOURIER TRANSFORM *parameters* $(a, b) = (1, 1)$,

$$\phi(t) = \mathcal{F}[P(x)] = \int_{-\infty}^{\infty} e^{itx} P(x)\, dx \tag{1}$$

$$= \int_{-\infty}^{\infty} P(x)\, dx + it \int_{-\infty}^{\infty} xP(x)\, dx$$

$$+ \tfrac{1}{2}(it)^2 \int_{-\infty}^{\infty} x^2 P(x)\, dx + \ldots \tag{2}$$

$$= \sum_{k=0}^{\infty} \frac{(it)^k}{k!} \mu'_k \tag{3}$$

$$= 1 + it\mu'_1 - \tfrac{1}{2} t^2 \mu'_2 - \frac{1}{3!} it^3 \mu'_3 + \frac{1}{4!} t^4 \mu'_4 + \ldots, \tag{4}$$

where μ'_n (sometimes also denoted ν_n) is the nth MOMENT about 0 and $\mu'_0 \equiv 1$ (Abramowitz and Stegun 1972, p. 928). A DISTRIBUTION is *not* uniquely specified by its MOMENTS, but is uniquely specified by its characteristic function,

$$P(x) = \mathcal{F}^{-1}[\phi(t)] = \frac{1}{2\pi} \int_{-\infty}^{\infty} e^{-itx} \phi(t)\, dt \tag{5}$$

(Papoulis 1984, p. 155).

The characteristic function can therefore be used to generate RAW MOMENTS,

$$\phi^{(n)}(0) \equiv \left[\frac{d^n \phi}{dt^n}\right]_{t=0} = i^n \mu'_n \tag{6}$$

or the CUMULANTS κ_n,

$$\ln \phi(t) \equiv \sum_{n=o}^{\infty} \kappa_n \frac{(it)^n}{n!}. \tag{7}$$

See also CUMULANT, MOMENT, MOMENT-GENERATING

FUNCTION, PROBABILITY DENSITY FUNCTION

Characteristic Function (Set)

Given a SUBSET A of a larger set, the characteristic function χ_A is identically one on A, and is zero elsewhere.

These kinds of functions get their own name because they are useful tools. It is easier to say "the characteristic function of the rationals" or "the characteristic function of PRIMES" than to keep repeating the definition.

A characteristic function is a special case of a SIMPLE FUNCTION.

See also SET, SIMPLE FUNCTION

Charlier Series

A class of formal series expansions in derivatives of a distribution $\Psi(t)$ which may (but need not) be the NORMAL DISTRIBUTION FUNCTION

$$\Phi(t) \equiv \frac{1}{\sqrt{2\pi}}\, e^{-t^2/2}$$

and moments or other measured parameters. Edgeworth series are known as the Charlier series or Gram-Charlier series. Let $\psi(t)$ be the CHARACTERISTIC FUNCTION of the function $\Psi(t)$, and γ_r its CUMULANTS. Similarly, let $F(t)$ be the distribution to be approximated, $f(t)$ its CHARACTERISTIC FUNCTION, and κ_r its CUMULANTS. By definition, these quantities are connected by the formal series

$$f(t) = \exp\left[\sum_{r=1}^{\infty}(\kappa_r - \gamma_r)\frac{(it)^r}{r!}\right]\psi(t)$$

(Wallace 1958). Integrating by parts gives $(it)^r\psi(t)$ as the CHARACTERISTIC FUNCTION of $(-1)^r\Psi^{(r)}(x)$, so the formal identity corresponds pairwise to the identity

$$F(x)=\exp\left[\sum_{r=1}^{\infty}(\kappa_r-\gamma_r)\frac{(-D)^r}{r!}\right]\Psi(x),$$

where D is the DIFFERENTIAL OPERATOR. The most important case $\Psi(t)=\Phi(t)$ was considered by Chebyshev (1890), Charlier (1905), and Edgeworth (1905).

Expanding and collecting terms according to the order of the derivatives gives the so-called Gram-Charlier A-Series, which is identical to the formal expansion of $F-\Psi$ in Hermite polynomials. The A-series converges for functions F whose tails approach zero faster than $\Psi'^{1/2}$ (Cramér 1925, Wallace 1958, Szego 1975).

Charlier's Check

A check which can be used to verify correct computations in a table of grouped classes. For example, consider the following table with specified class limits and frequencies f. The class marks x_i are then computed as well as the rescaled frequencies u_i, which are given by

$$u_i=\frac{f_i-x_0}{c}, \tag{1}$$

where the class mark is taken as $x_0=74.5$ and the class interval is $c=10$. The remaining quantities are then computed as follows.

class limits	x_i	f_i	$(\mu)_n$	f_iu_i	$f_iu_i^2$	$f_i(u_i+1)^2$
30–39	34.5	2	−4	−8	32	18
40–49	44.5	3	−3	−9	27	12
50–59	54.5	11	−2	−22	44	11
60–69	64.5	20	−1	−20	20	0
70–79	74.5	32	0	0	0	32
80–89	84.5	25	1	25	25	100
90–99	94.5	7	2	14	28	63
total		100		−20	176	236

In order to compute the VARIANCE, note that

$$s_u^2=\frac{\sum_i f_iu_i^2}{\sum_i f_i}-\left(\frac{\sum_i f_iu_i}{\sum_i f_i}\right)^2 \tag{2}$$

$$=\frac{176}{100}-\left(\frac{-20}{100}\right)^2=1.72, \tag{3}$$

so the VARIANCE of the original data is

$$s_x^2=c^2s_u^2=172. \tag{4}$$

Charlier's check makes use of the additional column $f_i(u_i+1)^2$ added to the right side of the table. By noting that the identity

$$\sum_i f_i(u_i+1)^2=\sum_i f_i(u_i^2+2u_i+1)$$
$$=\sum_i f_iu_i^2+2\sum_i f_iu_i+\sum_i f_i, \tag{5}$$

connects columns five through seven, it can be checked that the computations have been done correctly. In the example above,

$$236=176+2(-20)+100, \tag{6}$$

so the computations pass Charlier's check.

Chart

COORDINATE CHART

Chasles-Cayley-Brill Formula

The number of coincidences of a (ν, ν') correspondence of value γ on a curve of GENUS p is given by

$$\nu+\nu'+2p\gamma.$$

See also ZEUTHEN'S THEOREM

References

Coolidge, J. L. *A Treatise on Algebraic Plane Curves.* New York: Dover, p. 129, 1959.

Chasles's Contact Theorem

If a one-parameter family of curves has index N and class M, the number tangent to a curve of order n_1 and class m_1 in general position is

$$m_1 N + n_1 M.$$

References

Coolidge, J. L. *A Treatise on Algebraic Plane Curves.* New York: Dover, p. 436, 1959.

Chasles's Polars Theorem

If the TRILINEAR POLARS of the VERTICES of a TRIANGLE are distinct from the respectively opposite sides, they meet the sides in three COLLINEAR points.

See also COLLINEAR, TRIANGLE, TRILINEAR POLAR

Chasles's Theorem

If two projective PENCILS of curves of orders n and n' have no common curve, the LOCUS of the intersections of corresponding curves of the two is a curve of order $n+n'$ through all the centers of either PENCIL. Conversely, if a curve of order $n+n'$ contains all centers of a PENCIL of order n to the multiplicity demanded by NOETHER'S FUNDAMENTAL THEOREM, then it is the LOCUS of the intersections of corresponding curves of this PENCIL and one of order n' projective therewith.

See also NOETHER'S FUNDAMENTAL THEOREM, PENCIL

Chebyshev

This entry contributed by RONALD M. AARTS

A number of spellings of "Chebyshev" (which is the spelling used exclusively in this work) are commonly found in the literature. These include Tchebicheff, Cebysev, Tschebyscheff, Chebishev, and Tschebyscheff (Clenshaw).

References

Clenshaw, C. W. *Mathematical Tables, Vol. 5: Chebyshev Series for Mathematical Functions.* Department of Scientific and Industrial Research.

Chebyshev Approximation Formula

Using a CHEBYSHEV POLYNOMIAL OF THE FIRST KIND $T(x)$, define

$$\begin{aligned} c_j &\equiv \frac{2}{N} \sum_{k=1}^{N} f(x_k) T_j(x_k) \\ &= \frac{2}{N} \sum_{k=1}^{N} f\left[\cos\left\{\frac{\pi(k-\frac{1}{2})}{N}\right\}\right] \cos\left\{\frac{\pi j(k-\frac{1}{2})}{N}\right\}. \end{aligned}$$

Then

$$f(x) \approx \sum_{k=0}^{N-1} c_k T_k(x) - \tfrac{1}{2} c_0.$$

It is exact for the N zeros of $T_N(x)$. This type of approximation is important because, when truncated, the error is spread smoothly over $[-1, 1]$. The Chebyshev approximation formula is very close to the MINIMAX POLYNOMIAL.

Chebyshev Constants

N.B. A detailed online essay by S. Finch was the starting point for this entry.

The constants

$$\lambda_{m,n} = \inf_{r \in R_{m,n}} \sup_{x \geq 0} |e^{-x} - r(x)|,$$

where

$$r(x) = \frac{p(x)}{q(x)},$$

p and q are mth and nth order POLYNOMIALS, and $R_{m,n}$ is the set all RATIONAL FUNCTIONS with REAL coefficients.

See also ONE-NINTH CONSTANT, RATIONAL FUNCTION

References

Chebyshev Differential Equation

$$(1-x^2)\frac{d^2y}{dx^2}-x\,\frac{dy}{dx}+\alpha^2y=0 \tag{1}$$

for $|x|<1$. The Chebyshev differential equation has regular SINGULARITIES at -1, 1, and ∞. It can be solved by series solution using the expansions

$$y=\sum_{n=0}^{\infty} a_nx^n \tag{2}$$

$$y'=\sum_{n=0}^{\infty} na_nx^{n-1}=\sum_{n=1}^{\infty} na_nx^{n-1}=\sum_{n=0}^{\infty}(n+1)a_{n+1}x^n \tag{3}$$

$$y''=\sum_{n=0}^{\infty}(n+1)na_{n+1}x^{n-1}=\sum_{n=1}^{\infty}(n+1)na_{n+1}x^{n-1}$$
$$=\sum_{n=0}^{\infty}(n+2)(n+1)a_{n+2}x^n. \tag{4}$$

Now, plug (2–4) into the original equation (1) to obtain

$$(1-x^2)\sum_{n=0}^{\infty}(n+2)(n+1)a_{n+2}x^n$$

$$-x\sum_{n=0}^{\infty}(n+1)n_{n+1}x^n+\alpha^2\sum_{n=0}^{\infty}a_nx^n=0 \tag{5}$$

$$\sum_{n=0}^{\infty}(n+2)(n+1)a_{n+2}x^n-\sum_{n=0}^{\infty}(n+2)(n+1)a_{n+2}x^{n+2}$$
$$-\sum_{n=0}^{\infty}(n+1)a_{n+2}x^{n+1}+\alpha^2\sum_{n=0}^{\infty}a_nx^n=0 \tag{6}$$

$$\sum_{n=0}^{\infty}(n+2)(n+1)a_{n+2}x^n-\sum_{n=2}^{\infty}n(n-1)a_nx^{n+2}$$
$$-\sum_{n=1}^{\infty}na_nx^n+\alpha^2\sum_{n=0}^{\infty}a_nx^n=0 \tag{7}$$

$$2\cdot 1a_2+3\cdot 2a_3x-1\cdot ax+\alpha^2a_0+\alpha^2a_1x$$
$$+\sum_{n=2}^{\infty}[(n+2)(n+1)a_{n+2}-n(n-1)a_n-na_n+\alpha^2a_n]x^n$$
$$=0 \tag{8}$$

$$(2a_2+\alpha^2a_0)+[(\alpha^2-1)a_1+6a_3]x$$
$$+\sum_{n=2}^{\infty}[(n+2)(n+1)a_{n+2}+(\alpha^2-n^2)a_n]x^n=0, \tag{9}$$

so

$$2a_2+\alpha^2a_0=0 \tag{10}$$

$$(\alpha^2-1)a_1+6a_3=0, \tag{11}$$

and by induction,

$$a_{n+2}=\frac{n^2-\alpha^2}{(n+1)(n+2)}\,a_n \tag{12}$$

for $n=2, 3, \ldots$.
Since (10) and (11) are special cases of (12), the general RECURRENCE RELATION can be written

$$a_{n+2}=\frac{n^2-\alpha^2}{(n+1)(n+2)}\,a_n \tag{13}$$

for $n=0, 1, \ldots$. From this, we obtain for the EVEN COEFFICIENTS

$$a_2=\frac{-\alpha^2}{2}\,a_0 \tag{14}$$

$$a_4=\frac{2^2-\alpha^2}{3\cdot 4}\,a_2=\frac{(2^2-\alpha^2)(-\alpha^2)}{1\cdot 2\cdot 3\cdot 4}\,a_0 \tag{15}$$

$$a_{2n}=\frac{[(2n)^2-\alpha^2][(2n-2)^2-\alpha^2]\cdots(-\alpha^2)}{(2n)!}\,a_0. \tag{16}$$

and for the ODD COEFFICIENTS

$$a_3=\frac{1-\alpha^2}{6}\,a_0 \tag{17}$$

$$a_5 = \frac{3^2 - \alpha^2}{4 \cdot 5} a_3 = \frac{(3^2 - \alpha^2)(1^2 - \alpha^2)}{5!} a_1 \quad (18)$$

$$a_{2n-1} = \frac{[(2n-1)^2 - \alpha^2][(2n-3)^2 - \alpha^2] \cdots [1^2 - \alpha^2]}{(2n+1)!} a_1. \quad (19)$$

The even coefficients $k = 2n$ can be given in closed form by as

$$a_{k \text{ even}} = a_0 \prod_{j=1}^{k/2} (k-2j)^2 - \alpha^2 = \frac{2^{k-1} \pi\alpha \csc(\frac{1}{2}\pi\alpha)}{\Gamma(1 - \frac{1}{2}k - \frac{1}{2}\alpha)\Gamma(1 - \frac{1}{2}k + \frac{1}{2}\alpha)} a_0, \quad (20)$$

and the odd coefficients $k = 2n - 1$ as

$$a_{k \text{ odd}} = a_1 \prod_{j=1}^{(k-1)/2} (k-2j)^2 - \alpha^2 = \frac{2^{k-1} \pi\alpha \sec(\frac{1}{2}\pi\alpha)}{\Gamma(1 - \frac{1}{2}k - \frac{1}{2}\alpha)\Gamma(1 - \frac{1}{2}k + \frac{1}{2}\alpha)} a_1. \quad (21)$$

The general solution is then given by summing over all indices,

$$y = a_0 \left[1 + \sum_{k=2,4...}^{\infty} \frac{a_{k \text{ even}}}{k!} x^k\right] + \left[x + \sum_{k=3,5...}^{\infty} \frac{a_{k \text{ odd}}}{k!} x^k\right], \quad (22)$$

which can be done in closed form as

$$y = a_0 \cos(\alpha \sin^{-1} x) + \frac{a_1}{\alpha} \sin(\alpha \sin^{-1} x). \quad (23)$$

Performing a change of variables gives the equivalent form of the solution

$$y = b_1 \cos(\alpha \cos^{-1} x) + b_2 \sin(\alpha \cos^{-1} x) \quad (24)$$

$$= b_1 T_\alpha(x) + b_2 \sqrt{1-x^2}\, U_{\alpha-1}(x), \quad (25)$$

where $T_n(x)$ is a CHEBYSHEV POLYNOMIAL OF THE FIRST KIND and $U_n(x)$ is a CHEBYSHEV POLYNOMIAL OF THE SECOND KIND. Another equivalent form of the solution is given by

$$y = c_1 \cosh[\alpha \ln(x + \sqrt{x^2 - 1})] + ic_2 \sinh[\alpha \ln(x + \sqrt{x^2 - 1})]. \quad (26)$$

See also CHEBYSHEV POLYNOMIAL OF THE FIRST KIND, CHEBYSHEV POLYNOMIAL OF THE SECOND KIND

Chebyshev Functions

The function defined by

$$\theta(n) \equiv \sum_{i=1}^{n} \ln p_i = \ln\left(\prod_{p \le n} p\right), \quad (1)$$

where p_i is the ith PRIME (left figure), so

$$\lim_{x \to \infty} \frac{x}{\theta(x)} = 1 \quad (2)$$

(right figure). The function has asymptotic behavior

$$\theta(n) \sim n \quad (3)$$

(Bach and Shallit 1996; Hardy 1999, p. 28). The notation $\vartheta(n)$ is also commonly used for this function (Hardy 1999, p. 27).

Chebyshev also defined the related function

$$\psi(n) \equiv \sum_{\substack{p,\ \nu \\ p^\nu \le n}} \ln p, \quad (4)$$

which is equal to the summatory MANGOLDT FUNCTION and is given by the logarithm of the LEAST COMMON MULTIPLE of the numbers from 1 to n. The values of LCM$(1, 2, \cdots, n)$ for $n = 1, 2, ...$ are 1, 2, 6, 12, 60, 60, 420, 840, 2520, 2520, ... (Sloane's A003418). For example,

$$\psi(10) = \ln 2520 = 3 \ln 2 + 2 \ln 3 + \ln 5 + \ln 7. \quad (5)$$

The function has asymptotic behavior

$$\psi(n) \sim n \quad (6)$$

(Hardy 1999, p. 27).

According to Hardy (1999, p. 27), the functions $\theta(n)$ and $\psi(n)$ are in some ways more natural than the PRIME COUNTING FUNCTION $\pi(x)$ since they deal with multiplication of primes instead of the counting of them.

Chebyshev Inequality

Apply MARKOV'S INEQUALITY with $a \equiv k^2$ to obtain

$$P[(x-\mu)^2 \geq k^2] \leq \frac{\langle (x-\mu)^2 \rangle}{k^2} = \frac{\sigma^2}{k^2}. \quad (1)$$

Therefore, if a RANDOM VARIABLE x has a finite MEAN μ and finite VARIANCE σ^2, then $\forall k \geq 0$,

$$P(|x-\mu| \geq k) \leq \frac{\sigma^2}{k^2} \quad (2)$$

$$P(|x-\mu| \geq k\sigma) \leq \frac{1}{k^2}. \quad (3)$$

Chebyshev Phenomenon

PRIME QUADRATIC EFFECT

Chebyshev Polynomial of the First Kind

A set of ORTHOGONAL POLYNOMIALS defined as the solutions to the CHEBYSHEV DIFFERENTIAL EQUATION and denoted $T_n(x)$. They are used as an approximation to a LEAST SQUARES FIT, and are a special case of the ULTRASPHERICAL POLYNOMIAL with $\alpha = 0$. They are also intimately connected with trigonometric MULTIPLE-ANGLE FORMULAS. The Chebyshev polynomials of the first kind are denoted $T_n(x)$, and are implemented in *Mathematica* as `ChebyshevT[n, x]`. They are normalized such that $T_n(1) = 1$. The first few polynomials are illustrated above for $x \in [-1, 1]$ and $n = 1, 2, ..., 5$.

The Chebyshev polynomials of the first kind can be obtained from the GENERATING FUNCTIONS

$$g_1(t, x) \equiv \frac{1-t^2}{1-2xt+t^2} = T_0(x) + 2\sum_{n=1}^{\infty} T_n(x) t^n \quad (1)$$

and

$$g_2(t, x) \equiv \frac{1 - xt}{1 - 2xt + t^2} = \sum_{n=0}^{\infty} T_n(x)t^n \tag{2}$$

for $|x| \leq 1$ and $|t| < 1$ (Beeler *et al.* 1972, Item 15). (A closely related GENERATING FUNCTION is the basis for the definition of CHEBYSHEV POLYNOMIAL OF THE SECOND KIND.)

The polynomials can also be defined in terms of the sums

$$T_n(x) = \frac{n}{2} \sum_{r=0}^{\lfloor n/2 \rfloor} \frac{(-1)^r}{n-r} \binom{n-r}{r} (2x)^{n-2r} \tag{3}$$

$$T_n(x) = \cos(\cos^{-1} x) = \sum_{m=0}^{\lfloor n/2 \rfloor} \binom{n}{2m} x^{n-2m}(x^2-1)^m, \tag{4}$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT and $\lfloor x \rfloor$ is the FLOOR FUNCTION, or the product

$$T_n(x) = 2^{n-1} \prod_{k=1}^{n} \left\{ x - \cos\left[\frac{(2k-1)\pi}{2n}\right] \right\} \tag{5}$$

(Zwillinger 1995, p. 696).

T_n also satisfy the curious DETERMINANT equation

$$T_n = \begin{vmatrix} x & 1 & 0 & 0 & \cdots & 0 & 0 \\ 1 & 2x & 1 & 0 & \ddots & 0 & 0 \\ 0 & 1 & 2x & 1 & \ddots & 0 & 0 \\ 0 & 0 & 1 & 2x & \ddots & 0 & 0 \\ 0 & 0 & 0 & 1 & \ddots & 1 & 0 \\ \vdots & \ddots & \ddots & \ddots & \ddots & \ddots & 1 \\ 0 & 0 & 0 & 0 & \cdots & 1 & 2x \end{vmatrix}. \tag{6}$$

The Chebyshev polynomials of the first kind are a special case of the JACOBI POLYNOMIALS $P_n^{(\alpha,\beta)}$ with $\alpha = \beta = -1/2$,

$$T_n(x) = \frac{P_n^{(-1/2,-1/2)}(x)}{P_n^{(-1/2,-1/2)}(1)} = {}_2F_1(-n, -n; \tfrac{1}{2}; \tfrac{1}{2}(1-x)), \tag{7}$$

where ${}_2F_1(a, b; c; x)$ is a HYPERGEOMETRIC FUNCTION (Koekoek and Swarttouw 1998).

Zeros occur when

$$x = \cos\left[\frac{\pi\left(k - \frac{1}{2}\right)}{n}\right] \tag{8}$$

for $k = 1, 2, ..., n$. Extrema occur for

$$x = \cos\left(\frac{\pi k}{n}\right), \tag{9}$$

where $k = 0, 1, \ldots, n$. At maximum, $T_n(x) = 1$, and at minimum, $T_n(x) = -1$. The Chebyshev POLYNOMIALS are ORTHONORMAL with respect to the WEIGHTING FUNCTION $(1-x^2)^{-1/2}$

$$\int_{-1}^{1} \frac{T_m(x)T_n(x)\,dx}{\sqrt{1-x^2}} = \begin{cases} \frac{1}{2}\pi\delta_{nm} & \text{for } m \neq 0, n \neq 0 \\ \pi & \text{for } m = n = 0, \end{cases} \tag{10}$$

where δ_{mn} is the KRONECKER DELTA. Chebyshev polynomials of the first kind satisfy the additional discrete identity

$$\sum_{k=1}^{m} T_i(x_k)T_j(x_k) = \begin{cases} \frac{1}{2}m\delta_{ij} & \text{for } i \neq 0, j \neq 0 \\ m & \text{for } i = j = 0, \end{cases} \tag{11}$$

where x_k for $k = 1, ..., m$ are the m zeros of $T_m(x)$. They also satisfy the RECURRENCE RELATIONS

$$T_{n+1}(x) = 2xT_n(x) - T_{n-1}(x) \tag{12}$$

$$T_{n+1}(x) = xT_n(x) - \sqrt{(1-x^2)\{1 - [T_n(x)]^2\}} \tag{13}$$

for $n \geq 1$. They have a COMPLEX integral representation

$$T_n(x) = \frac{1}{4\pi i} \int_\gamma \frac{(1-z^2)z^{-n-1}\,dz}{1 - 2xz + z^2} \tag{14}$$

and a Rodrigues representation

$$T_n(x) = \frac{(-1)^n \sqrt{\pi}(1-x^2)^{1/2}}{2n(n-\frac{1}{2})!} \frac{d^n}{dx^n}[(1-x^2)^{n-1/2}]. \tag{15}$$

Using a FAST FIBONACCI TRANSFORM with multiplication law

$$(A, B)(C, D) = (AD + BC + 2xAC, BD - AC) \tag{16}$$

gives

$$T_{n+1}(x), -T_n(x) = (T_1(x), -T_0(x))(1, 0)^n. \tag{17}$$

Using GRAM-SCHMIDT ORTHONORMALIZATION in the range $(-1,1)$ with WEIGHTING FUNCTION $(1-x^2)^{(-1/2)}$ gives

$$p_0(x) = 1 \tag{18}$$

$$p_1(x) = \left[x - \frac{\int_{-1}^{1} x(1-x^2)^{-1/2}\,dx}{\int_{-1}^{1} (1-x^2)^{-1/2}\,dx} \right]$$

$$= x - \frac{[-1(1-x^2)^{1/2}]_{-1}^{1}}{[\sin^{-1} x]_{-1}^{1}} = x \tag{19}$$

$$p_2(x) = \left[x - \frac{\int_{-1}^{1} x^3(1-x^2)^{-1/2}\,dx}{\int_{-1}^{1} x^2(1-x^2)^{-1/2}\,dx} \right] x - \left[\frac{\int_{-1}^{1} x^2(1-x^2)^{-1/2}\,dx}{\int_{-1}^{1} (1-x^2)^{-1/2}\,dx} \right] \cdot 1$$

$$= [x - 0]x - \frac{\frac{\pi}{2}}{\pi} = x^2 - \tfrac{1}{2}, \qquad (20)$$

etc. Normalizing such that $T_n(1) = 1$ gives

$$T_0(x) = 1$$

$$T_1(x) = x$$

$$T_2(x) = 2x^2 - 1$$

$$T_3(x) = 4x^3 - 3x$$

$$T_4(x) = 8x^4 - 8x^2 + 1$$

$$T_5(x) = 16x^5 - 20x^3 + 5x$$

$$T_6(x) = 32x^6 - 48x^4 + 18x^2 - 1$$

The Chebyshev polynomial of the first kind is related to the BESSEL FUNCTION OF THE FIRST KIND $J_n(x)$ and MODIFIED BESSEL FUNCTION OF THE FIRST KIND $I_n(x)$ by the relations

$$J_n(x) = i^n T_n\left(i \frac{d}{dx}\right) J_0(x) \qquad (21)$$

$$I_n(x) = T_n\left(\frac{d}{dx}\right) I_0(x). \qquad (22)$$

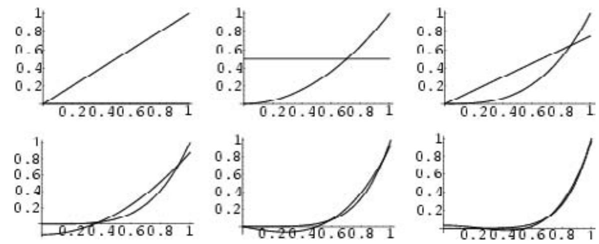
Letting $x \equiv \cos\theta$ allows the Chebyshev polynomials of the first kind to be written as

$$T_n(x) = \cos(n\theta) = \cos(n \cos^{-1} x). \qquad (23)$$

The second linearly dependent solution to the transformed differential equation

$$\frac{d^2 T_n}{d\theta^2} + n^2 T_n = 0 \qquad (24)$$

is then given by



$$V_n(x) = \sin(n\theta) = \sin(n \cos^{-1} x), \qquad (25)$$

which can also be written

$$V_n(x) = \sqrt{1-x^2}\, U_{n-1}(x), \qquad (26)$$

where U_n is a CHEBYSHEV POLYNOMIAL OF THE SECOND KIND. Note that $V_n(x)$ is therefore *not* a POLYNOMIAL.

The triangle of RESULTANTS $\rho(T_n(x), T_k(x))$ is given by {0}, {−1, 0}, {0, −4, 0}, {1, 16, 64, 0}, {0, −16, 0, 4096, 0}, ... (Sloane's A054375).

The POLYNOMIALS

$$p_n(x) = x^n - 2^{1-n} T_n(x) \qquad (27)$$

of degree $n - 2$, the first few of which are

$$p_1(x) = 0$$
$$p_2(x) = \tfrac{1}{2}$$
$$p_3(x) = \tfrac{3}{4}x$$
$$p_4(x) = x^2 - \tfrac{1}{8}$$
$$p_5(x) = \tfrac{5}{16}(4x^3 - x)$$

are the POLYNOMIALS of degree $< n$ which stay closest to x_n in the interval $(-1, 1)$. The maximum deviation is 2^{1-n} at the $n + 1$ points where

$$x = \cos\left(\frac{k\pi}{n}\right), \qquad (28)$$

for $k = 0, 1, ..., n$ (Beeler *et al.* 1972).

Chebyshev Polynomial of the Second Kind

A modified set of Chebyshev POLYNOMIALS defined by a slightly different GENERATING FUNCTION. They arise in the development of four-dimensional SPHERICAL HARMONICS in angular momentum theory. They are a special case of the ULTRASPHERICAL POLYNOMIAL with $\alpha = 1$. They are also intimately connected with trigonometric MULTIPLE-ANGLE FORMULAS. The Chebyshev polynomials of the second kind are denoted $U_n(x)$, and implemented in *Mathematica* as ChebyshevU[n, x]. The polynomials $U_n(x)$ are illustrated above for $x \in [-1, 1]$ and $n = 1, 2, ..., 5$.

The defining GENERATING FUNCTION of the Chebyshev polynomials of the second kind is

$$g_2(t, x) = \frac{1}{1 - 2xt + t^2} = \sum_{n=0}^{\infty} U_n(x)t^n \quad (1)$$

for $|x| < 1$ and $|t| < 1$. To see the relationship to a CHEBYSHEV POLYNOMIAL OF THE FIRST KIND $T(x)$, take $\partial g/\partial t$,

$$\frac{\partial g}{\partial t} = -(1 - 2xt + t^2)^{-2}(-2x + 2t)$$

$$= 2(t - x)(1 - 2xt + t^2)^{-2} = \sum_{n=0}^{\infty} nU_n(x)t^{n-1}. \quad (2)$$

Multiply (2) by t,

$$(2t^2 - 2xt)(1 - 2xt + t^2)^{-2} = \sum_{n=0}^{\infty} nU_n(x)t^n \quad (3)$$

and take (3) minus (2),

$$\frac{(2t^2 - 2tx) - (1 - 2xt + t^2)}{(1 - 2xt + t^2)^2} = \frac{t^2 - 1}{(1 - 2xt + t^2)^2}$$

$$= \sum_{n=0}^{\infty} (n - 1)U_n(x)t^n. \quad (4)$$

The Rodrigues representation is

$$U_n(x) = \frac{(-1)^n(n + 1)\sqrt{\pi}}{2^{n+1}(n + \frac{1}{2})!(1 - x^2)^{1/2}} \frac{d^n}{dx^n}[(1 - x^2)^{n+1/2}]. \quad (5)$$

The polynomials can also be defined in terms of the sums

$$U_n(x) = \sum_{r=0}^{\lfloor n/2 \rfloor} (-1)^r \binom{n - r}{r} (2x)^{n-2r}$$

$$= \sum_{m=0}^{\lceil n/2 \rceil} \binom{n + 1}{2m + 1} x^{n-2m}(x^2 - 1)^m, \quad (6)$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION and $\lceil x \rceil$ is the CEILING FUNCTION, or in terms of the product

$$U_n(x) = 2^n \prod_{k=1}^{n} \left[x - \cos\left(\frac{k\pi}{n + 1}\right)\right] \quad (7)$$

(Zwillinger 1995, p. 696).

$U_n(x)$ also obey the interesting DETERMINANT identity

$$U_n = \begin{vmatrix} 2x & 1 & 0 & 0 & \cdots & 0 & 0 \\ 1 & 2x & 1 & 0 & \ddots & 0 & 0 \\ 0 & 1 & 2x & 1 & \ddots & 0 & 0 \\ 0 & 0 & 1 & 2x & \ddots & 0 & 0 \\ 0 & 0 & 0 & 1 & \ddots & 1 & 0 \\ \vdots & \ddots & \ddots & \ddots & \ddots & \ddots & 1 \\ 0 & 0 & 0 & 0 & \cdots & 1 & 2x \end{vmatrix}. \quad (8)$$

The Chebyshev polynomials of the second kind are a special case of the JACOBI POLYNOMIALS $P_n^{(\alpha,\beta)}$ with $\alpha = \beta = 1/2$,

$$U_n(x) = (n + 1)\frac{P_n^{(1/2,\ 1/2)}(x)}{P_n^{(1/2,\ 1/2)}(1)}$$

$$= {}_2F_1(-n,\ n + 2;\ \tfrac{3}{2};\ \tfrac{1}{2}(1 - x)), \quad (9)$$

where ${}_2F_1(a,\ b;\ c;\ x)$ is a HYPERGEOMETRIC FUNCTION (Koekoek and Swarttouw 1998).

The first few POLYNOMIALS are

$$U_0(x) = 1$$

$$U_1(x) = 2x$$

$$U_2(x) = 4x^2 - 1$$

$$U_3(x) = 8x^3 - 4x$$

$$U_4(x) = 16x^4 - 12x^2 + 1$$

$$U_5(x) = 32x^5 - 32x^3 + 6x$$

$$U_6(x) = 64x^6 - 80x^4 + 24x^2 - 1.$$

Letting $x \equiv \cos\theta$ allows the Chebyshev polynomials of the second kind to be written as

$$U_n(x) = \frac{\sin[(n+1)]\theta]}{\sin\theta}. \tag{10}$$

The second linearly dependent solution to the transformed differential equation is then given by

$$W_n(x) = \frac{\cos[(n+1)\theta]}{\sin\theta}, \tag{11}$$

which can also be written

$$W_n(x) = (1-x^2)^{-1/2} T_{n+1}(x), \tag{12}$$

where $T_n(x)$ is a Chebyshev polynomial of the first kind. Note that $W_n(x)$ is therefore *not* a polynomial.

The triangle of resultants $\rho(U_n(x), U_k(x))$ is given by {0}, {–4, 0}, {0, –64, 0}, {16, 256, 4096, 0}, {0, 0, 0, 1048576, 0}, ... (Sloane's A054376).

Chebyshev Quadrature

A Gaussian quadrature-like formula for numerical estimation of integrals. It uses weighting function $W(x) = 1$ in the interval [–1, 1] and forces all the weights to be equal. The general formula is

$$\int_{-1}^{1} f(x)\,dx = \frac{2}{n}\sum_{i=1}^{n} f(x_i).$$

The abscissas are found by taking terms up to y^n in the Maclaurin series of

$$s_n(y) = \exp\left\{\tfrac{1}{2}n\left[-2 + \ln(1-y)\left(1-\frac{1}{y}\right) + \ln(1+y)\left(1+\frac{1}{y}\right)\right]\right\},$$

and then defining

$$G_n(x) \equiv x^n s_n\left(\frac{1}{x}\right).$$

The roots of $G_n(x)$ then give the abscissas. The first few values are

$$G_0(x) = 1$$
$$G_1(x) = x$$
$$G_2(x) = \tfrac{1}{3}(3x^2 - 1)$$
$$G_3(x) = \tfrac{1}{2}(2x^3 - x)$$
$$G_4(x) = \tfrac{1}{45}(45x^4 - 30x^2 + 1)$$
$$G_5(x) = \tfrac{1}{72}(72x^5 - 60x^3 + 7x)$$
$$G_6(x) = \tfrac{1}{105}(105x^6 - 105x^4 + 21x^2 - 1)$$
$$G_7(x) = \tfrac{1}{6480}(6480x^7 - 7560x^5 + 2142x^3 - 149x)$$
$$G_8(x) = \tfrac{1}{42525}(42525x^8 - 56700x^6 + 20790x^4 - 2220x^2 - 43)$$
$$G_9(x) = \tfrac{1}{22400}(22400x^9 - 33600x^7 + 15120x^5 - 2280x^3 + 53x).$$

Because the roots are all real for $n \leq 7$ and $n = 9$ only (Hildebrand 1956), these are the only permissible orders for Chebyshev quadrature. The error term is

$$E_n = \begin{cases} c_n \dfrac{f^{(n+1)}(\xi)}{(n+1)!} & n \text{ odd} \\ c_n \dfrac{f^{(n+2)}(\xi)}{(n+2)!} & n \text{ even}, \end{cases}$$

where

$$c_n = \begin{cases} \displaystyle\int_{-1}^{1} xG_n(x)\,dx & n \text{ odd} \\ \displaystyle\int_{-1}^{1} x^2 G_n(x)\,dx & n \text{ even}. \end{cases}$$

The first few values of c_n are 2/3, 8/45, 1/15, 32/945, 13/756, and 16/1575 (Hildebrand 1956). Beyer (1987) gives abscissas up to $n = 7$ and Hildebrand (1956) up to $n = 9$.

Chebyshev Sum Inequality

If

$$a_1 \geq a_2 \geq \ldots \geq a_n$$

$$b_1 \geq b_2 \geq \ldots \geq b_n,$$

then

$$n \sum_{k=1}^{n} a_k b_k \geq \left(\sum_{k=1}^{n} a_k\right)\left(\sum_{k=1}^{n} b_k\right).$$

This is true for *any* distribution.

Chebyshev-Gauss Quadrature

Also called CHEBYSHEV QUADRATURE. A GAUSSIAN QUADRATURE over the interval [–1, 1] with WEIGHTING FUNCTION $W(x) = (1-x^2)^{-1/2}$ (Abramowitz and Stegun 1972, p. 889). The ABSCISSAS for quadrature order n are given by the roots of the CHEBYSHEV POLYNOMIAL OF THE FIRST KIND $T_n(x)$, which occur symmetrically about 0. The WEIGHTS are

$$w_i = -\frac{A_{n+1}\gamma_n}{A_n T_n'(x_i) T_{n+1}(x_i)} = \frac{A_n}{A_{n-1}} \frac{\gamma_{n-1}}{T_{n-1}(x_i) T_n'(x_i)}, \quad (1)$$

where A_n is the COEFFICIENT of x_n in $T_n(x)$. For HERMITE POLYNOMIALS,

$$A_n = 2^{n-1}, \quad (2)$$

so

$$\frac{A_{n+1}}{A_n} = 2. \quad (3)$$

Additionally,

$$\gamma_n = \tfrac{1}{2}\pi, \quad (4)$$

so

$$w_i = -\frac{\pi}{T_{n+1}(x_i) T_n'(x_i)}. \quad (5)$$

Since

$$T_n(x) = \cos(n \cos^{-1} x), \quad (6)$$

the ABSCISSAS are given explicitly by

$$x_i = \cos\left[\frac{(2i-1)\pi}{2n}\right]. \quad (7)$$

Since

$$T'_n(x_i) = \frac{(-1)^{i+1} n}{\alpha_i} \quad (8)$$

$$T_{n+1}(x_i) = (-1)^i \sin \alpha_i, \quad (9)$$

where

$$\alpha_i = \frac{(2i-1)\pi}{2n}, \quad (10)$$

all the WEIGHTS are

$$w_i = \frac{\pi}{n}. \quad (11)$$

The explicit FORMULA is then

$$\int_{-1}^{1} \frac{f(x)\,dx}{\sqrt{1-x^2}} = \frac{\pi}{n} \sum_{k=1}^{n} f\left[\cos\left(\frac{2k-1}{2n}\pi\right)\right] + \frac{2\pi}{2^{2n}(2n)!} f^{(2n)}(\xi). \quad (12)$$

The following two tables give the numerical and analytic values for the first few points and weights.

n	x_i	w_i

Chebyshev-Radau Quadrature

A GAUSSIAN QUADRATURE-like FORMULA over the interval [–1, 1] which has WEIGHTING FUNCTION $W(x) = x$. The general FORMULA is

$$\int_{-1}^{1} x f(x)\,dx = \sum_{i=1}^{n} w_i [f(x_i) - f(-x_i)].$$

n	x_i	w_i
1	0.7745967	0.4303315
2	0.5002990	0.2393715
	0.8922365	0.2393715
3	0.4429861	0.1599145
	0.7121545	0.1599145
	0.9293066	0.1599145

CHEBYSHEV-GAUSS QUADRATURE

Chebyshev's Theorem

There are at least two theorems known as Chebyshev's theorem. The first is BERTRAND'S POSTULATE, and the second is a weak form of the PRIME NUMBER THEOREM stating that the ORDER OF MAGNITUDE of the PRIME COUNTING FUNCTION $\pi(x)$ is

$$\pi(x) \asymp \frac{x}{\ln x},$$

where $\asymp$ denotes "is ASYMPTOTIC to" (Hardy and Wright 1979, p. 9).

Chebyshev-Sylvester Constant

In 1891, Chebyshev and Sylvester showed that for sufficiently large x, there exists at least one PRIME NUMBER p satisfying

$$x < p < (1+\alpha)x,$$

where $\alpha = 0.092\ldots$. Since the PRIME NUMBER THEOREM shows the above inequality is true for all $\alpha > 0$ for sufficiently large x, this constant is only of historical interest.

Checkerboard

CHESSBOARD

Checker-Jumping Problem

Seeks the minimum number of checkers placed on a board required to allow pieces to move by a sequence of horizontal or vertical jumps (removing the piece jumped over) n rows beyond the forward-most initial checker. The first few cases are 2, 4, 8, 20. It is, however, impossible to reach level five.

See also CHECKERS

References

Honsberger, R. *Mathematical Gems II.* Washington, DC: Math. Assoc. Amer., pp. 23–28, 1976.

Checkers

Schroeppel (1972) estimated that there are about 10^{12} possible positions. However, this disagrees with the estimate of Jon Schaeffer of 5×10^{20} plausible positions, with 10^{18} reachable under the rules of the game. Because "solving" checkers may require only the SQUARE ROOT of the number of positions in the search space (i.e., 10^9), there is hope that some day checkers may be solved (i.e., it may be possible to guarantee a win for the first player to move before the game is even started; Dubuque 1996).

Depending on how they are counted, the number of EULERIAN CIRCUITS on an $n \times n$ checkerboard are either 1, 40, 793, 12800, 193721, ... (Sloane's A006240) or 1, 13, 108, 793, 5611, 39312, ... (Sloane's A006239).

Checksum

A sum of the digits in a given transmission modulo some number. The simplest form of checksum is a parity bit appended on to 7-bit numbers (e.g., ASCII characters) such that the total number of 1s is always EVEN ("even parity") or ODD ("odd parity"). A significantly more sophisticated checksum is the CYCLIC REDUNDANCY CHECK (or CRC), which is based on the algebra of polynomials over the integers (mod 2). It is substantially more reliable in detecting transmission errors, and is one common error-checking protocol used in modems.

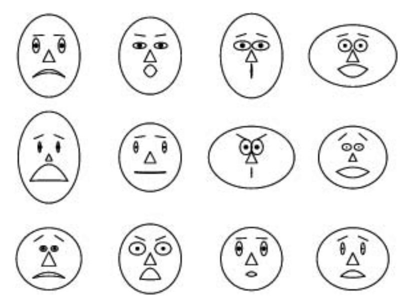
Chern Class

A GADGET defined for COMPLEX VECTOR BUNDLES. The Chern classes of a COMPLEX MANIFOLD are the Chern classes of its TANGENT BUNDLE. The ith Chern class is an OBSTRUCTION to the existence of $(n - i + 1)$ everywhere COMPLEX linearly independent VECTOR FIELDS on that VECTOR BUNDLE. The ith Chern class is in the $(2i)$th cohomology group of the base SPACE.



See also CHERN NUMBER, OBSTRUCTION, PONTRYAGIN CLASS, STIEFEL-WHITNEY CLASS

Chern Number

The Chern number is defined in terms of the CHERN CLASS of a MANIFOLD as follows. For any collection CHERN CLASSES such that their cup product has the same DIMENSION as the MANIFOLD, this cup product can be evaluated on the MANIFOLD's FUNDAMENTAL CLASS. The resulting number is called the Chern number for that combination of Chern classes. The most important aspect of Chern numbers is that they are COBORDISM invariant.

See also CHERN CLASS, PONTRYAGIN NUMBER, STIEFEL-WHITNEY NUMBER

Chernoff Face

A way to display n variables on a 2-D surface. For instance, let x be eyebrow slant, y be eye size, z be nose length, etc. The above figures show faces produced using 10 characteristics–head eccentricity, eye size, eye spacing, eye eccentricity, pupil size, eyebrow slant, nose size, mouth shape, mouth size, and mouth opening)–each assigned one of 10 possible values, generated using *Mathematica* (S. Dickson).

Chess

Chess is a game played on an 8×8 BOARD, called a CHESSBOARD, of alternating black and white squares. Pieces with different types of allowed moves are placed on the board, a set of black pieces in the first

two rows and a set of white pieces in the last two rows. The pieces are called the bishop (2), king (1), knight (2), pawn (8), queen (1), and rook (2). The object of the game is to capture the opponent's king. It is believed that chess was played in India as early as the sixth century AD.

Hardy (1999, p. 17) estimated the number of possible games of chess as

$$10^{10^{50}}.$$

In a game of 40 moves, the number of possible board positions is at least 10^{120} according to Peterson (1996). However, this value does not agree with the 10^{40} possible positions given by Beeler *et al.* (1972). This value was obtained by estimating the number of pawn positions (in the no-captures situation, this is 15^8), times all pieces in all positions, dividing by 2 for each of the (rook, knight) which are interchangeable, dividing by 2 for each pair of bishops (since half the positions will have the bishops on the same color squares). There are more positions with one or two captures, since the pawns can then switch columns (Schroeppel 1996). Shannon (1950) gave the value

$$P(40) \approx \frac{64!}{32!(8!)^2(2!)^6} \approx 10^{43}.$$

The number of chess games which end in exactly n plies (including games that mate in fewer than n plies) for $n = 1, 2, 3, \ldots$ are 20, 400, 8902, 197742, 4897256, 120921506, 3284294545, ... (K. Thompson, Sloane's A006494). Rex Stout's fictional detective Nero Wolfe quotes the number of possible games after ten moves as follows: "Wolfe grunted. One hundred and sixty-nine million, five hundred and eighteen thousand, eight hundred and twenty-nine followed by twenty-one ciphers. The number of ways the first ten moves, both sides, may be played" (Stout 1983). The number of chess positions after n moves for $n = 1, 2, \ldots$ are 20, 400, 5362, 71852, 809896?, 9132484?, ... (Schwarzkopf 1994, Sloane's A019319).

Cunningham (1889) incorrectly found 197,299 games and 71,782 positions after the fourth move. C. Flye St. Marie was the first to find the correct number of positions after four moves: 71,852. Dawson (1946) gives the source as *Intermediare des Mathematiques* (1895), but K. Fabel writes that Flye St. Marie corrected the number 71,870 (which he found in 1895) to 71,852 in 1903. The history of the determination of the chess sequences is discussed in Schwarzkopf (1994).

The analysis of chess is extremely complicated due to the many possible options at each move. Steinhaus (1983, pp. 11–14), as well as many entire books, consider clever end-game positions which may be analyzed completely.

Two problems in recreational mathematics ask

1. How many pieces of a given type can be placed on a CHESSBOARD without any two attacking.
2. What is the smallest number of pieces needed to occupy or attack every square.

The answers are given in the following table (Madachy 1979).

Piece	Max.	Min.
BISHOPS	14	8
KINGS	16	9
KNIGHTS	32	12
QUEENS	8	5
ROOKS	8	8

Chessboard

A board containing 8×8 squares alternating in color between black and white on which the game of CHESS is played. The checkerboard is identical to the chessboard except that chess's black and white squares are colored red and white in CHECKERS.

It is impossible to cover a chessboard from which two opposite corners have been removed with DOMINOES. Sprague (1963) considered the problem of "rolling" five cubes, each which an upright letter "A" on its top, on a chessboard. Here "rolling" means the cubes are moved from square to adjacent square by being tipped over along an edge (as one might move a heavy box) in a series of quarter turns. If five such cubes are initially arranged in the shape of a plus sign with the edges of the of plus sign aligned with the upper and left corners of a chessboard (top left in above figure), then it is impossible to obtain a straight row or column with all "A"s on top and oriented identically. The best that can be done is to place four out of the five "A"s in the same orientation and facing upward, with the remaining "A" also facing upward and rotated a quarter turn, illustrated above in the bottom row (Gardner 1984, pp. 75–78).

The above plot shows a chessboard centered at (0, 0) and its INVERSE about a small circle also centered at (0, 0) (Gardner 1984, pp. 244–245; Dixon 1991).

Chi Distribution

The probability density function and cumulative distribution function are

$$P_n(x)=\frac{2^{1-n/2}x^{n-1}e^{-x^2/2}}{\Gamma(\tfrac{1}{2}n)} \tag{1}$$

$$D_n(x)=Q(\tfrac{1}{2}n,\ \tfrac{1}{2}x^2), \tag{2}$$

where Q is the REGULARIZED GAMMA FUNCTION.

$$\mu=\frac{\sqrt{2}\,\Gamma(\tfrac{1}{2}(n+1))}{\Gamma(\tfrac{1}{2}n)} \tag{3}$$

$$\sigma^2=\frac{2[\Gamma(\tfrac{1}{2}n)\Gamma(1+\tfrac{1}{2}n)-\Gamma^2(\tfrac{1}{2}(n+1))]}{\Gamma^2(\tfrac{1}{2}n)} \tag{4}$$

$$\gamma_1=\frac{2\Gamma^3(\tfrac{1}{2}(n+1))-3\Gamma(\tfrac{1}{2}n)\Gamma(\tfrac{1}{2}(n+1))\Gamma(1+\tfrac{1}{2}n)}{[\Gamma(\tfrac{1}{2}n)\Gamma(1+\tfrac{1}{2}n)-\Gamma^2(\tfrac{1}{2}(n+1))]^{3/2}} + \frac{\Gamma^2(\tfrac{1}{2}n)\Gamma\left(\frac{3+n}{2}\right)}{[\Gamma(\tfrac{1}{2}n)\Gamma(1+\tfrac{1}{2}n)-\Gamma^2(\tfrac{1}{2}(n+1))]^{3/2}} \tag{5}$$

$$\gamma_2=\frac{-3\Gamma^4(\tfrac{1}{2}(n+1))+6\Gamma(\tfrac{1}{2}n)\Gamma^2(\tfrac{1}{2}(n+1))\Gamma(1+\tfrac{1}{2}n)}{\left[\Gamma(\tfrac{1}{2}n)\Gamma\left(\frac{2+n}{2}\right)-\Gamma^2(\tfrac{1}{2}(n+1))\right]^2} + \frac{-4\Gamma^2(\tfrac{1}{2}n)\Gamma(\tfrac{1}{2}(n+1))\Gamma\left(\frac{3+n}{2}\right)+\Gamma^3(\tfrac{1}{2}n)\Gamma\left(\frac{4+n}{2}\right)}{\left[\Gamma(\tfrac{1}{2}n)\Gamma\left(\frac{2+n}{2}\right)-\Gamma^2(\tfrac{1}{2}(n+1))\right]^2}, \tag{6}$$

where μ is the MEAN, σ^2 the VARIANCE, γ_1 the SKEWNESS, and γ_2 the KURTOSIS. For $n=1$, the χ distribution is a HALF-NORMAL DISTRIBUTION with $\theta=1$. For $n=2$, it is a RAYLEIGH DISTRIBUTION with $\sigma=1$.

See also CHI-SQUARED DISTRIBUTION, HALF-NORMAL DISTRIBUTION, RAYLEIGH DISTRIBUTION

Chi Inequality

The inequality

$$(j+1)a_j + a_i \geq (j+1)i,$$

which is satisfied by all A-SEQUENCE.

Child

A node which is one EDGE further away from a given node in a ROOTED TREE.

See also ROOT NODE, ROOTED TREE, SIBLING

Chinese Hypothesis

A PRIME p always satisfies the condition that $2^p - 2$ is divisible by p. However, this condition is not true *exclusively* for PRIMES (e.g., $2^{341} - 2$ is divisible by $341 = 11 \cdot 31$). COMPOSITE NUMBERS n (such as 341) for which $2^n - 2$ is divisible by n are called POULET NUMBERS, and are a special class of FERMAT PSEUDOPRIMES. The Chinese hypothesis is a special case of FERMAT'S LITTLE THEOREM.

Chinese Remainder Theorem

Let r and s be POSITIVE INTEGERS which are RELATIVELY PRIME and let a and b be any two INTEGERS. Then there is an INTEGER N such that

$$N \equiv a \pmod{r} \tag{1}$$

and

$$N \equiv b \pmod{s}. \tag{2}$$

Moreover, N is uniquely determined modulo rs. An equivalent statement is that if $(r, s) = 1$, then every pair of RESIDUE CLASSES modulo r and s corresponds to a simple RESIDUE CLASS modulo rs.

The theorem can also be generalized as follows. Given a set of simultaneous CONGRUENCES

$$x \equiv a_i \pmod{m_i} \tag{3}$$

for $i = 1, \ldots, r$ and for which the m_i are pairwise RELATIVELY PRIME, the solution of the set of CONGRUENCES is

$$x = a_1 b_1 \frac{M}{m_1} + \ldots + a_r b_r \frac{M}{m_r} \pmod{M}, \tag{4}$$

where

$$M \equiv m_1 m_2 \cdots m_r \tag{5}$$

and the b_i are determined from

$$b_i \frac{M}{m_i} \equiv 1 \pmod{m_i}. \tag{6}$$

Chinese Rings

BAGUENAUDIER

Chiral

Having forms of different HANDEDNESS which are not mirror-symmetric.

See also DISSYMMETRIC, ENANTIOMER, HANDEDNESS, MIRROR IMAGE, REFLEXIBLE

Chiral Knot

A chiral knot is a KNOT which is *not* capable of being continuously deformed into its own MIRROR IMAGE.

See also AMPHICHIRAL KNOT, KNOT SYMMETRY

Chi-Squared Distribution

A χ^2 distribution is a GAMMA DISTRIBUTION with $\theta \equiv 2$ and $\alpha \equiv r/2$, where r is the number of DEGREES OF FREEDOM. If Y_i have NORMAL INDEPENDENT distributions with MEAN 0 and VARIANCE 1, then

$$\chi^2 \equiv \sum_{i=1}^{r} Y_i^2 \tag{1}$$

is distributed as χ^2 with r DEGREES OF FREEDOM. If χ_i^2 are independently distributed according to a χ^2 distribution with r_1, r_2, ..., r_k DEGREES OF FREEDOM, then

$$\sum_{j=1}^{k} \chi_j^2 \tag{2}$$

is distributed according to χ^2 with $r \equiv \Sigma_{j=1}^{k} r_j$ DEGREES OF FREEDOM. The probability density function is

$$P_r(x) = \frac{x^{r/2-1}e^{-x/2}}{\Gamma(\frac{1}{2}r)2^{r/2}} \tag{3}$$

for $x \in [0, \infty)$. The cumulative distribution function is then

$$D_r(\chi^2) = \int_0^{\chi^2} \frac{t^{r/2-1}e^{-t/2}\,dt}{\Gamma(\frac{1}{2}r)2^{r/2}} = \frac{\gamma(\frac{1}{2}r, \frac{1}{2}\chi^2)}{\Gamma(\frac{1}{2}r)} = P(\tfrac{1}{2}r, \tfrac{1}{2}\chi^2), \tag{4}$$

where $P(a, z)$ is a REGULARIZED GAMMA FUNCTION. The CONFIDENCE INTERVALS can be found by finding the value of x for which $D_r(x)$ equals a given value. The MOMENT-GENERATING FUNCTION of the χ^2 distribution is

$$M(t) = (1-2t)^{-r/2} \tag{5}$$

$$R(t) \equiv \ln M(t) = -\tfrac{1}{2} r \ln(1-2t) \tag{6}$$

$$R'(t) = \frac{r}{1-2t} \tag{7}$$

$$R''(t) = \frac{2r}{(1-2t)^2}, \tag{8}$$

so

$$\mu = R'(0) = r \tag{9}$$

$$\sigma^2 = R''(0) = 2r \tag{10}$$

$$\gamma_1 = 2\sqrt{\frac{2}{r}} \tag{11}$$

$$\gamma_2 = \frac{12}{r}. \tag{12}$$

The nth MOMENT about zero for a distribution with r DEGREES OF FREEDOM is

$$m_n' = 2^n \frac{\Gamma(n+\frac{1}{2}r)}{\Gamma(\frac{1}{2}r)} = r(r+2)\cdots(r+2n-2), \tag{13}$$

and the moments about the MEAN are

$$\mu_2 = 2r \tag{14}$$

$$\mu_3 = 8r \tag{15}$$

$$\mu_4 = 12r(r+4). \tag{16}$$

The nth CUMULANT is

$$\kappa_n = 2^n \Gamma(n)(\tfrac{1}{2}r) = 2^{n-1}(n-1)!r. \tag{17}$$

The MOMENT-GENERATING FUNCTION is

$$\begin{aligned} M(t) &= e^{rt/\sqrt{2r}}\left(1-\frac{2t}{\sqrt{2r}}\right)^{-r/2} \\ &= \left[e^{t\sqrt{2/r}}\left(1-\sqrt{\frac{2}{r}}\,t\right)\right]^{-r/2} \\ &= \left[1-\frac{t^2}{r}-\frac{1}{3}\left(\frac{2}{r}\right)^{3/2} t^3 - \ldots\right]^{-r/2}. \end{aligned} \tag{18}$$

As $r \to \infty$,

$$\lim_{r\to\infty} M(t) = e^{t^2/2}, \tag{19}$$

so for large r,

$$\sqrt{2\chi^2} = \sqrt{\sum_i \frac{(x_i-\mu_i)^2}{\sigma_i^2}} \tag{20}$$

is approximately a GAUSSIAN DISTRIBUTION with MEAN $\sqrt{2r}$ and VARIANCE $\sigma^2 = 1$. Fisher showed that

$$\frac{\chi^2 - r}{\sqrt{2r-1}} \tag{21}$$

is an improved estimate for moderate r. Wilson and Hilferty showed that

$$\left(\frac{\chi^2}{r}\right)^{1/3} \tag{22}$$

is a nearly GAUSSIAN DISTRIBUTION with MEAN $\mu = 1 - 2/(9r)$ and VARIANCE $\sigma^2 = 2/(9r)$.

In a GAUSSIAN DISTRIBUTION,

$$P(x)\,dx = \frac{1}{\sigma\sqrt{2\pi}}\, e^{-(x-\mu)^2/2\sigma^2}\,dx, \tag{23}$$

let

$$z \equiv (x-\mu)^2/\sigma^2. \tag{24}$$

Then

$$dz = \frac{2(x-\mu)^2}{\sigma^2}\,dx = \frac{2\sqrt{z}}{\sigma}\,dx \tag{25}$$

so

$$dx = \frac{\sigma}{2\sqrt{z}}\,dz. \tag{26}$$

But

$$P(z)\,dz = 2P(x)\,dx, \tag{27}$$

so

$$P(x)\,dx = 2\,\frac{1}{\sigma\sqrt{2\pi}}\,e^{-z/2}\,dz = \frac{1}{\sigma\sqrt{\pi}}\,e^{-z/2}\,dz. \tag{28}$$

This is a χ^2 distribution with $r=1$, since

$$P(z)\,dz = \frac{z^{1/2-1}e^{-z/2}}{\Gamma(\frac{1}{2})2^{1/2}}\,dz = \frac{x^{-1/2}e^{-1/2}}{\sqrt{2\pi}}\,dz. \tag{29}$$

If X_i are independent variates with a NORMAL DISTRIBUTION having MEANS μ_i and VARIANCES σ_i^2 for $i=1, \ldots, n$, then

$$\tfrac{1}{2}\chi^2 \equiv \sum_{i=1}^{n} \frac{(x_i-\mu_i)^2}{2\sigma_i^2} \tag{30}$$

is a GAMMA DISTRIBUTION variate with $\alpha = n/2$,

$$P(\tfrac{1}{2}\chi^2)d(\tfrac{1}{2}\chi^2) = \frac{1}{\Gamma(\frac{1}{2}n)}\,e^{-\chi^2/2}(\tfrac{1}{2}\chi^2)^{(n/2)-1}d(\tfrac{1}{2}\chi^2). \tag{31}$$

The noncentral chi-squared distribution is given by

$$P(x) = 2^{-n/2}e^{-(\lambda+x)/2}x^{n/2-1}F(\tfrac{1}{2}n,\ \tfrac{1}{4}\lambda x), \tag{32}$$

where

$$F(a,\ z) \equiv \frac{{}_0F_1(;\ a;\ z)}{\Gamma(a)}, \tag{33}$$

${}_0F_1$ is the CONFLUENT HYPERGEOMETRIC LIMIT FUNCTION and Γ is the GAMMA FUNCTION. The MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

$$\mu = \lambda + n \tag{34}$$

$$\sigma^2 = 2(2\lambda + n) \tag{35}$$

$$\gamma_1 = \frac{2\sqrt{2}(3\lambda+n)}{(2\lambda+n)^{3/2}} \tag{36}$$

$$\gamma_2 = \frac{12(4\lambda+n)}{(2\lambda+n)^2}. \tag{37}$$

Chi-Squared Test

Let the probabilities of various classes in a distribution be p_1, p_2, ..., p_k, with means m_1, m_2, ... The expected frequency

$$\chi_s^2 = \sum_{i=1}^{k} \frac{(m_i - Np_i)^2}{Np_i}$$

is a measure of the deviation of a sample from expectation. Karl Pearson proved that the limiting distribution of χ_s^2 is χ^2 (Kenney and Keeping 1951, pp. 114–116).

$$\begin{aligned}\Pr(\chi^2 \geq \chi_s^2) &= \int_{\chi_s^2}^{\infty} f(\chi^2)\,d(\chi^2)\\ &= \frac{1}{2}\int_{\chi_s^2}^{\infty} \frac{\left(\frac{\chi^2}{2}\right)^{(k-3)/2}}{\Gamma\left(\frac{k-1}{2}\right)}\,e^{-\chi^2/2}\,d(\chi^2)\\ &= 1 - \frac{\Gamma\left(\frac{1}{2}\chi_s^2, \frac{k-1}{2}\right)}{\Gamma\left(\frac{k-1}{2}\right)}\\ &= 1 - I\left(\frac{\chi_s^2}{\sqrt{2(k-1)}}, \frac{k-3}{2}\right),\end{aligned}$$

where $I(x,\ n)$ is PEARSON'S FUNCTION. There are some subtleties involved in using the χ^2 test to fit curves (Kenney and Keeping 1951, pp. 118–119).

When fitting a one-parameter solution using χ^2, the best-fit parameter value can be found by calculating χ^2 at three points, plotting against the parameter values of these points, then finding the minimum of a PARABOLA fit through the points (Cuzzi 1972, pp. 162–168).

Chmutov Surface

An ALGEBRAIC SURFACE with affine equation

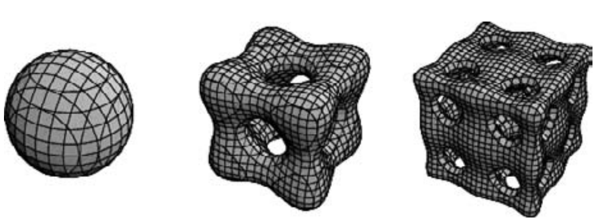
$$P_d(x_1, x_2) + T_d(x_3) = 0, \quad (1)$$

where $T_d(x)$ is a CHEBYSHEV POLYNOMIAL OF THE FIRST KIND and $P_d(x_1, x_2)$ is a polynomial defined by

$$P_d(x_1, x_2) = \begin{vmatrix} x_1 & 1 & 0 & \cdots & 0 & 0 & 0 \\ 2x_2 & x_1 & 1 & \ddots & 0 & 0 & 0 \\ 3 & x_2 & x_1 & \ddots & \ddots & \ddots & \vdots \\ 0 & 1 & x_2 & \ddots & 1 & 0 & 0 \\ 0 & 0 & 1 & \ddots & x_1 & 1 & 0 \\ \vdots & \ddots & \ddots & \ddots & x_2 & x_1 & 1 \\ 0 & 0 & 0 & \cdots & 1 & x_2 & x_1 \end{vmatrix} + \begin{vmatrix} x_2 & 1 & 0 & \cdots & 0 & 0 & 0 \\ 2x_1 & x_2 & 1 & \ddots & 0 & 0 & 0 \\ 3 & x_1 & x_2 & \ddots & \ddots & \ddots & \vdots \\ 0 & 1 & x_1 & \ddots & 1 & 0 & 0 \\ 0 & 0 & 1 & \ddots & x_2 & 1 & 0 \\ \vdots & \ddots & \ddots & \ddots & x_1 & x_2 & 1 \\ 0 & 0 & 0 & \cdots & 1 & x_1 & x_2 \end{vmatrix}, \quad (2)$$

where the matrices have dimensions $d \times d$. These represent surfaces in $\mathbb{C}P^3$ with only ORDINARY DOUBLE POINTS as singularities. The first few surfaces are given by

$$x + y + z = 0 \quad (3)$$



$$x^2 + y^2 + 2z^2 = 1 + 2x + 2y \quad (4)$$

$$6 + x^3 + y^3 + 4z^3 = 3(2xy + z). \quad (5)$$

The dth order such surface has

$$N(d) = \begin{cases} \frac{1}{12}(5d^3 - 13d^2 + 12d) & \text{if } d \equiv 0 \pmod 6 \\ \frac{1}{12}(5d^3 - 13d^2 + 16d - 8) & \text{if } d \equiv 2,\ 4 \pmod 6 \\ \frac{1}{12}(5d^3 - 13d^2 + 13d - 4) & \text{if } d \equiv 1,\ 5 \pmod 6 \\ \frac{1}{12}(5d^3 - 14d^2 + 9d) & \text{if } d \equiv 3 \pmod 6 \end{cases}$$

singular points (Chmutov 1992), giving the sequence 0, 1, 3, 14, 28, 57, 93, 154, 216, 321, 425, 576, 732, 949, 1155, ... for $d = 1, 2, ...$ For a number of orders d, Chmutov surfaces have more ordinary double points than any other known equations of the same degree.

Based on Chmutov's equations, Banchoff (1991) defined the simpler set of surfaces

$$T_n(x) + T_n(y) + T_n(z) = 0, \quad (6)$$

where n is EVEN and $T_n(x)$ is again a CHEBYSHEV POLYNOMIAL OF THE FIRST KIND. For example, the surfaces illustrated above have orders 2, 4, and 6 are given by the equations

$$2(x^2 + y^2 + z^2) = 3 \quad (7)$$

$$3 + 8(x^4 + y^4 + z^4) = 8(x^2 + y^2 + z^2) \quad (8)$$

$$2[x^2(3 - 4x^2)^2 + y^2(3 - 4y^2)^2 + z^2(3 - 4z^2)^2] = 3. \quad (9)$$

Choice Axiom

AXIOM OF CHOICE

Choice Number

COMBINATION

Cholesky Decomposition

Given a symmetric POSITIVE DEFINITE MATRIX A, the Cholesky decomposition is an UPPER TRIANGULAR MATRIX U such that

$$\mathsf{A} = \mathsf{U}^{\mathrm{T}}\mathsf{U}.$$

Cholesky decomposition is implemented as `CholeskyDecomposition[m]` in the *Mathematica* add-on package ``LinearAlgebra`Cholesky` `` (which can be loaded with the command ``<<LinearAlgebra` ``).

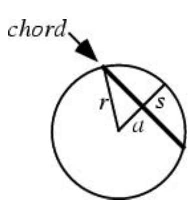
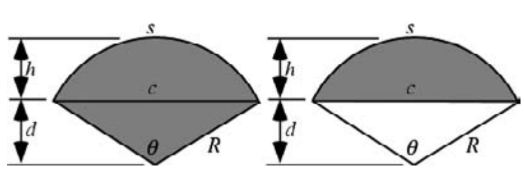
Choose

An alternative term for a BINOMIAL COEFFICIENT, in which $\binom{n}{k}$ is read as "n choose k." R. K. Guy suggested this pronunciation around 1950, when the notations ${}^nC_r$ and ${}_nC_r$ were commonly used. Leo Moser liked the pronunciation and he and others spread it around. It got the final seal of approval from Donald Knuth when he incorporated it into the TEX mathematical typesetting language as {n\choose k}.



See also BINOMIAL COEFFICIENT, MULTICHOOSE

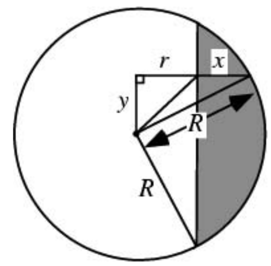
Choquet Theory



Erdos proved that there exist at least one PRIME OF THE FORM $4k+1$ and at least one PRIME OF THE FORM $4k+3$ between n and $2n$ for all $n>6$.

See also EQUINUMEROUS, PRIME NUMBER

Chord



The LINE SEGMENT joining two points on a curve. The term is often used to describe a LINE SEGMENT whose ends lie on a CIRCLE. In the above figure, r is the RADIUS of the CIRCLE, a is called the APOTHEM, and s the SAGITTA.

The shaded region in the left figure is called a SECTOR, and the shaded region in the right figure is called a SEGMENT.

All ANGLES inscribed in a CIRCLE and subtended by the same chord are equal. The converse is also true: The LOCUS of all points from which a given segment subtends equal ANGLES is a CIRCLE.

Given any closed convex curve, it is possible to find a point P through which three chords, inclined to one another at angles of $60°$, pass such that P is the MIDPOINT of all three (Wells 1991).

Let a CIRCLE of RADIUS R have a CHORD at distance r. The AREA enclosed by the CHORD, shown as the shaded region in the above figure, is then

$$A=2\int_0^{\sqrt{R^2-r^2}} x(y)\,dy. \tag{1}$$

But

$$y^2+(r+x)^2=R^2, \tag{2}$$

so

$$x(y)=\sqrt{R^2-y^2}-r \tag{3}$$

and

$$A=2\int_0^{\sqrt{R^2-r^2}} (\sqrt{R^2-y^2}-r)\,dy \tag{4}$$

$$=R^2\tan^{-1}\left[\sqrt{\left(\frac{R}{r}\right)^2-1}\right]-r\sqrt{R^2-r^2}. \tag{5}$$

Checking the limits, when $r=R$, $A=0$ and when $r\to 0$,

$$A=\tfrac{1}{2}\pi R^2, \tag{6}$$

the expected area of the SEMICIRCLE.

Chow Coordinates

A generalization of GRASSMANN COORDINATES to m-D ALGEBRAIC VARIETIES of degree d in P^n, where P^n is an n-D projective space. To define the Chow coordinates, take the intersection of an m-D ALGEBRAIC VARIETY Z of degree d by an $(n-m)$-D SUBSPACE U of P^n. Then the coordinates of the d points of intersection are algebraic functions of the GRASSMANN COORDINATES of U, and by taking a symmetric function of the algebraic functions, a HOMOGENEOUS POLYNOMIAL known as the Chow form of Z is obtained. The Chow coordinates are then the COEFFICIENTS of the Chow form. Chow coordinates can generate the smallest field of definition of a divisor.

Christoffel Formula

Let $\{p_n(x)\}$ be orthogonal POLYNOMIALS associated with the distribution $d\alpha(x)$ on the interval $[a, b]$. Also let

$$\rho \equiv c(x-x_1)(x-x_2)\cdots(x-x_l)$$

(for $c \neq 0$) be a POLYNOMIAL of order l which is NONNEGATIVE in this interval. Then the orthogonal polynomials $\{q(x)\}$ associated with the distribution $\rho(x)\,d\alpha(x)$ can be represented in terms of the polynomials $p_n(x)$ as

$$\rho(x)q_n(x) = \begin{vmatrix} p_n(x) & p_{n+1}(x) & \cdots & p_{n+l}(x) \\ p_n(x_1) & p_{n+1}(x_l) & \cdots & p_{n+l}(x_1) \\ \vdots & \vdots & \ddots & \vdots \\ p_n(x_l) & p_{n+1}(x_l) & \cdots & p_{n+l}(x_l) \end{vmatrix}.$$

In the case of a zero x_k of multiplicity $m > 1$, we replace the corresponding rows by the derivatives of order 0, 1, 2, ..., $m-1$ of the POLYNOMIALS $p_n(x_l)$, ..., $p_{n+l}(x_l)$ at $x = x_k$.

Christoffel Number

One of the quantities λ_i appearing in the GAUSS-JACOBI MECHANICAL QUADRATURE. They satisfy

$$\lambda_1 + \lambda_2 + \ldots + \lambda_n = \int_a^b d\alpha(x) = \alpha(b) - \alpha(a) \qquad (1)$$

and are given by

$$\lambda_\nu = \int_a^b \left[\frac{p_n(x)}{p_n'(x_\nu)(x - x_\nu)}\right]^2 d\alpha(x) \qquad (2)$$

$$\lambda_\nu = -\frac{k_{n+1}}{k_n}\frac{1}{p_{n+1}(x_\nu)p_n'(x_\nu)} \qquad (3)$$

$$= \frac{k_n}{k_{n-1}}\frac{1}{p_{n-1}(x_\nu)P_n'(x_\nu)} \qquad (4)$$

$$(\lambda_\nu)^{-1} = [p_0(x_\nu)]^2 + \ldots + [p_n(x_\nu)]^2, \qquad (5)$$

where k_n is the higher COEFFICIENT of $p_n(x)$.

Christoffel Symbol

The Christoffel symbols are tensor-like objects derived from a Riemannian metric g. They are used to study the geometry of the metric and appear, for example, in the geodesic equation. There are two closely related kinds of Christoffel symbols, the first kind $\Gamma_{i,\,j,\,k}$, and the second kind $\Gamma^{k}_{i,\,j}$.

It is always possible to pick a coordinate system on a Riemannian manifold such that the Christoffel symbol vanishes at a chosen point. In general relativity, Christoffel symbols are "gravitational forces," and the preferred coordinate system referred to above would be one attached to a body in free fall.

See also Christoffel Symbol of the First Kind, Christoffel Symbol of the Second Kind, Geodesic, Levi-Civita Connection, Riemannian Geometry

References

Carmo, M. *Differential Geometry of Curves and Surfaces.* Englewood Cliffs, NJ: Prentice-Hall, pp. 441–42, 1976.
Sternberg, S. *Differential Geometry.* New York: Chelsea, pp. 353–54, 1983.

Christoffel Symbol of the First Kind

The first type of tensor derived from a Riemannian metric g which is used to study the geometry of the metric. Christoffel symbols of the first kind are variously denoted $[ij,\,k]$, $\left[{}^{i}{}_{k}{}^{j}\right]$, $\boldsymbol{\Gamma}_{abc}$, or $\{ab,\ c\}$.

$$[ij,k] = g_{mk}\Gamma^{m}_{ij} \tag{1}$$

$$= g_{mk}\vec{e}^{m}\cdot\frac{\partial\vec{e}_i}{\partial q^i} \tag{2}$$

$$= \vec{e}_k\cdot\frac{\partial\vec{e}_i}{\partial q^j}, \tag{3}$$

where g_{mk} is the metric tensor, Γ^{m}_{ij} is a Christoffel symbol of the second kind, and

$$\vec{e}_i \equiv \frac{\partial\vec{r}}{\partial q^i} = h_i\hat{e}_i. \tag{4}$$

But

$$\frac{\partial g_{ij}}{\partial q^k} = \frac{\partial}{\partial q^k}(\vec{e}_i\cdot\vec{e}_j) = \frac{\partial\vec{e}_i}{\partial q^k}\cdot\vec{e}_j + \vec{e}_i\cdot\frac{\partial\vec{e}_j}{\partial q^k}$$
$$= [ik,\ j] + [jk,\ i], \tag{5}$$

so

$$[ab,\ c] = \tfrac{1}{2}(g_{ac,\ b} + g_{bc,\ a} - g_{ab,\ c}). \tag{6}$$

See also Christoffel Symbol, Christoffel Symbol of the Second Kind

References

Arfken, G. *Mathematical Methods for Physicists, 3rd ed.* Orlando, FL: Academic Press, pp. 160–67, 1985.

Christoffel Symbol of the Second Kind

The second type of tensor-like object derived from a Riemannian metric g which is used to study the geometry of the metric. Christoffel symbols of the second kind are variously denoted as $\left\{{}_{i}{}^{m}{}_{j}\right\}$ or Γ^{m}_{ij}. In the latter case, they are sometimes known as connection coefficients.

$$\Gamma^{m}_{ij} \equiv \vec{e}^{m}\cdot\frac{\partial\vec{e}_i}{\partial q^j} \tag{1}$$

$$= g^{km}[ij,\ k] \tag{2}$$

$$= \frac{1}{2}\,g^{km}\left(\frac{\partial g_{ik}}{\partial q^j} + \frac{\partial g_{jk}}{\partial q^i} - \frac{\partial g_{ij}}{\partial q^k}\right), \tag{3}$$

where g^{km} is the metric tensor. The Christoffel symbol of the second kind is related to the Christoffel symbol of the first kind $[bc,\ d]$ by

$$\Gamma^{a}_{bc} = g_{ad}\{bc,\ d\}. \tag{4}$$

Christoffel symbols of the second kind can also be defined by

$$\Gamma^{\vec{e}_\alpha}_{\vec{e}_\beta\vec{e}_\gamma} \equiv \vec{e}^{\alpha}\cdot(\nabla_{\vec{e}_\gamma}\vec{e}_\beta) \tag{5}$$

(long form) or

$$\Gamma^{\alpha}_{\beta\gamma} \equiv \vec{e}^{\alpha}\cdot(\nabla_{\gamma}\vec{e}_\beta), \tag{6}$$

(abbreviated form), and satisfy

$$\nabla_{\vec{e}_\gamma}\vec{e}_\beta = \Gamma^{\vec{e}_\alpha}_{\vec{e}_\beta\vec{e}_\gamma}\vec{e}_\alpha \tag{7}$$

(long form) and

$$\nabla_{\gamma}\vec{e}_\beta = \Gamma^{\alpha}_{\beta\gamma}\vec{e}_\alpha \tag{8}$$

(abbreviated form).

Christoffel symbols of the second kind are not tensors, but have tensor-like contravariant and covariant indices. Christoffel symbols of the second kind also do not transform as tensors. In fact, changing coordinates from $x_1, \ldots, x_n$ to $y_1, \ldots, y_n$ gives

$$\Gamma^{k'}_{ij} = \sum\frac{\partial^2 x_l}{\partial y_i\,\partial y_j}\frac{\partial y_k}{\partial x_l} + \sum\Gamma^{\mathrm{T}}_{rs}\frac{\partial x_r}{\partial y_i}\frac{\partial x_s}{\partial y_j}\frac{\partial y_k}{\partial x_t}. \tag{9}$$

However, a fully covariant Christoffel symbol of the second kind is given by

$$\Gamma_{\alpha\beta\gamma} \equiv \tfrac{1}{2}(g_{\alpha\beta,\,\gamma} + g_{\alpha\gamma,\,\beta} + c_{\alpha\beta\gamma} + c_{\alpha\gamma\beta} - c_{\beta\gamma\alpha}), \tag{10}$$

where the gs are the METRIC TENSORS, the cs are COMMUTATION COEFFICIENTS, and the commas indicate the COMMA DERIVATIVE. In an ORTHONORMAL BASIS, $g_{\alpha\beta,\,\gamma} = 0$ and $g_{\mu\gamma} = \delta_{\mu\gamma}$, so

$$\Gamma_{\alpha\beta\gamma} = \Gamma^{\mu}_{\alpha\beta} g_{\mu\gamma} = \Gamma^{\mu}_{\alpha\beta} = \tfrac{1}{2}(c_{\alpha\beta\gamma} + c_{\alpha\gamma\beta} - c_{\beta\gamma\alpha}) \tag{11}$$

and

$$\Gamma_{ijk} = 0 \quad \text{for } i \neq j \neq k \tag{12}$$

$$\Gamma_{iik} = -\frac{1}{2}\frac{\partial g_{ii}}{\partial x^k} \quad \text{for } i \neq k \tag{13}$$

$$\Gamma_{iji} = \Gamma_{jii} = \frac{1}{2}\frac{\partial g_{ii}}{\partial x^j} \tag{14}$$

$$\Gamma^k_{ij} = 0 \quad \text{for } i \neq j \neq k \tag{15}$$

$$\Gamma^k_{ii} = -\frac{1}{2g_{kk}}\frac{\partial g_{ii}}{\partial x^k} \quad \text{for } i \neq k \tag{16}$$

$$\Gamma^i_{ij} = \Gamma^i_{ji} = \frac{1}{2g_{ii}}\frac{\partial g_{ii}}{\partial x^j} = \frac{1}{2}\frac{\partial \ln g_{ii}}{\partial x^j}. \tag{17}$$

For TENSORS of RANK 3, the Christoffel symbols of the second kind may be concisely summarized in MATRIX form:

$$\Gamma^{\theta} \equiv \begin{bmatrix} \Gamma^{\theta}_{rr} & \Gamma^{\theta}_{r\theta} & \Gamma^{\theta}_{r\phi} \\ \Gamma^{\theta}_{\theta r} & \Gamma^{\theta}_{\theta\theta} & \Gamma^{\theta}_{\theta\phi} \\ \Gamma^{\theta}_{\phi r} & \Gamma^{\theta}_{\phi\theta} & \Gamma^{\theta}_{\phi\phi} \end{bmatrix}. \tag{18}$$

The Christoffel symbols are given in terms of the coefficients of the FIRST FUNDAMENTAL FORM E, F, and G by

$$\Gamma^1_{11} = \frac{GE_u - 2FF_u + FE_v}{2(EG - F^2)} \tag{19}$$

$$\Gamma^1_{12} = \frac{GE_v - FG_u}{2(EG - F^2)} \tag{20}$$

$$\Gamma^1_{22} = \frac{2GF_v - GG_u - FG_v}{2(EG - F^2)} \tag{21}$$

$$\Gamma^2_{11} = \frac{2EF_u - EE_v - FE_u}{2(EG - F^2)} \tag{22}$$

$$\Gamma^2_{12} = \frac{EG_u - FE_v}{2(EG - F^2)} \tag{23}$$

$$\Gamma^2_{22} = \frac{EG_v - 2FF_v + FG_u}{2(EG - F^2)}, \tag{24}$$

and $\Gamma^1_{21} = \Gamma^1_{12}$ and $\Gamma^2_{21} = \Gamma^2_{12}$. If $F = 0$, the Christoffel symbols of the second kind simplify to

$$\Gamma^1_{11} = \frac{E_u}{2E} \tag{25}$$

$$\Gamma^1_{12} = \frac{E_v}{2E} \tag{26}$$

$$\Gamma^1_{22} = -\frac{G_u}{2E} \tag{27}$$

$$\Gamma^2_{11} = -\frac{E_v}{2G} \tag{28}$$

$$\Gamma^2_{12} = \frac{G_u}{2G} \tag{29}$$

$$\Gamma^2_{22} = \frac{G_v}{2G} \tag{30}$$

(Gray 1997).

The following relationships hold between the Christoffel symbols of the second kind and coefficients of the first FUNDAMENTAL FORM,

$$\Gamma^1_{11}E + \Gamma^2_{11}F = \tfrac{1}{2}E_u \tag{31}$$

$$\Gamma^1_{12}E + \Gamma^2_{12}F = \tfrac{1}{2}E_v \tag{32}$$

$$\Gamma^1_{22}E + \Gamma^2_{22}F = F_v - \tfrac{1}{2}G_u \tag{33}$$

$$\Gamma^1_{11}F + \Gamma^2_{11}G = F_u - \tfrac{1}{2}E_v \tag{34}$$

$$\Gamma^1_{12}F + \Gamma^2_{12}G = \tfrac{1}{2}G_u \tag{35}$$

$$\Gamma^1_{22}F + \Gamma^2_{22}G = \tfrac{1}{2}G_v \tag{36}$$

$$\Gamma^1_{11} + \Gamma^2_{12} = (\ln\sqrt{EG - F^2})_u \tag{37}$$

$$\Gamma^1_{12} + \Gamma^2_{22} = (\ln\sqrt{EG - F^2})_v \tag{38}$$

(Gray 1997).

For a surface given in MONGE'S FORM $z = F(x, y)$,

$$\Gamma^k_{ij} = \frac{z_{ij} z_k}{1 + z_1^2 + z_2^2}. \tag{39}$$

Christoffel symbols of the second kind arise in the computation of GEODESICS. The GEODESIC EQUATION of free motion is

$$d\tau^2 = -\eta_{\alpha\beta}\, d\xi^{\alpha} d\xi^{\beta}, \tag{40}$$

or

$$\frac{d^2\xi^{\alpha}}{d\tau^2} = 0. \tag{41}$$

Expanding,

$$\frac{d}{d\tau}\left(\frac{\partial \xi^{\alpha}}{\partial x^{\mu}}\frac{dx^{\mu}}{d\tau}\right) = \frac{\partial \xi^{\alpha}}{\partial x^{\mu}}\frac{d^2 x^{\mu}}{d\tau^2} + \frac{\partial^2 \xi^{\alpha}}{\partial x^{\mu}\,\partial x^{\nu}}\frac{dx^{\mu}}{d\tau}\frac{dx^{\nu}}{d\tau} = 0 \tag{42}$$

$$\frac{\partial \xi^\alpha}{\partial x^\mu}\frac{d^2 x^\mu}{d\tau^2}\frac{\partial x^\lambda}{\partial \xi^\alpha}+\frac{\partial^2 \xi^\alpha}{\partial x^\mu\,\partial x^\nu}\frac{dx^\mu}{d\tau}\frac{dx^\nu}{d\tau}\frac{\partial x^\lambda}{\partial \xi^\alpha}=0. \tag{43}$$

But

$$\frac{\partial \xi^\alpha}{\partial x^\nu}\frac{\partial x^\lambda}{\partial \xi^\alpha}=\delta^\lambda_\mu, \tag{44}$$

so

$$\delta^\lambda_\mu\frac{d^2x^\mu}{d\tau^2}+\left(\frac{\partial^2 \xi^\alpha}{\partial x^\mu\,\partial x^\nu}\frac{\partial x^\lambda}{\partial \xi^\alpha}\right)\frac{dx^\mu}{d\tau}\frac{dx^\nu}{d\tau}$$
$$=\frac{d^2x^\lambda}{d\tau^2}+\Gamma^\lambda_{\mu\nu}\frac{dx^\mu}{d\tau}\frac{dx^\nu}{d\tau}, \tag{45}$$

where

$$\Gamma^\lambda_{\mu\nu}\equiv\frac{\partial^2 \xi^\alpha}{\partial x^\mu\,\partial x^\nu}\frac{\partial x^\lambda}{\partial \xi^\alpha}. \tag{46}$$

Christoffel-Darboux Formula

For three consecutive orders of an ORTHOGONAL POLYNOMIAL, the following relationship holds for $n=2, 3, ...$,

$$p_n(x)=(A_nx+B_n)p_{n-1}(x)-C_np_{n-2}(x), \tag{1}$$

where $A_n>0$, B_n, and $C_n>0$ are constants. Denoting the highest COEFFICIENT of $p_n(x)$ by k_n,

$$A_n=\frac{k_n}{k_{n-1}} \tag{2}$$

$$C_n=\frac{A_n}{A_{n-1}}=\frac{k_nk_{n-2}}{k^2_{n-1}}. \tag{3}$$

Then

$$p_0(x)p_0(y)+\ldots+p_n(x)p_n(y)$$
$$=\frac{k_n}{k_{n+1}}\frac{p_{n+1}(x)p_n(y)-p_n(x)p_{n+1}(y)}{x-y}. \tag{4}$$

In the special case of $x=y$, (4) gives

$$[p_0(x)]^2+\ldots+[p_n(x)]^2$$
$$=\frac{k_n}{k_{n+1}}[p'_{n+1}(x)p_n(x)-p'_n(x)p_{n+1}(x)]. \tag{5}$$

Chromatic Number

The fewest number of colors $\gamma(G)$ necessary to color the vertices of GRAPH or regions of a SURFACE (Skiena 1990, p. 210). The chromatic number is the smallest positive integer z such that the CHROMATIC POLYNOMIAL $\pi_G(z)>0$. Calculating the chromatic number of a GRAPH is an NP-COMPLETE PROBLEM (Skiena 1990, pp. 211–12).

For any two positive integers g and k, there exists a graph of girth at least g and chromatic number at least k (Erdos 1961, Lovász 1968; Skiena 1990, p. 215).

The chromatic number of a surface of GENUS g is given by the HEAWOOD CONJECTURE,

$$\gamma(g)=\left\lfloor\tfrac{1}{2}(7+\sqrt{48g+1})\right\rfloor,$$

where $\lfloor x\rfloor$ is the FLOOR FUNCTION. $\gamma(g)$ is sometimes also denoted $\chi(g)$ (which is unfortunate, since $\chi(g)=2-2g$ commonly refers to the EULER CHARACTERISTIC). For $g=0, 1, ...$, the first few values of $\chi(g)$ are 4,

7, 8, 9, 10, 11, 12, 12, 13, 13, 14, 15, 15, 16, ... (Sloane's A000934).

Erdos (1959) proved that there are graphs with arbitrarily large GIRTH and CHROMATIC NUMBER (Bollobás and West 2000).

Chromatic Polynomial

A POLYNOMIAL $\pi_G(z)$ of a GRAPH G which counts the number of ways to color g with exactly z colors. For example, the CUBICAL GRAPH has chromatic polynomial

$$\pi_G(z) = z^8 - 12z^7 + 66z^6 - 214z^5 + 441z^4 - 572z^3 + 423z^2 - 133z, \quad (1)$$

so the number of 1-, 2-, ... colorings are 0, 2, 114, 2652, 29660, 198030, ... The chromatic polynomial of a graph g in the variable z can be determined using ChromaticPolynomial[g, z] in the *Mathematica* add-on package DiscreteMath`Combinatorica` (which can be loaded with the command <<DiscreteMath`).

The chromatic polynomial of a DISCONNECTED GRAPH is the product of the chromatic polynomials of its CONNECTED COMPONENTS. The chromatic polynomial of a graph of order n has degree n, with leading coefficient 1 and constant term 0. Furthermore, the coefficients alternate signs, and the coefficient of the $(n-1)$st term is $-e$, where e is the number of edges. Interestingly, $\pi_G(-1)$ is equal to the number of acyclic orientations of G (Stanley 1973).

Except for special cases (such as TREES), the calculation of $\Pi_G(z)$ is exponential in the minimum number of edges in G and the COMPLEMENT GRAPH $\bar{G}$ (Skiena 1990, p. 211), and calculating the chromatic polynomial of a GRAPH is at least an NP-COMPLETE PROBLEM (Skiena 1990, pp. 211–12).

Tutte (1970) showed that the chromatic polynomial of a planar triangulation possess a ROOT close to $\phi^2 = \phi + 1 = 2.618033\ldots$, where ϕ is the GOLDEN MEAN. More precisely, if n is the number of VERTICES of G, then

$$P_G(\phi^2) \leq \phi^{5-n} \quad (2)$$

(Tutte 1970, Le Lionnais 1983).

Read (1968) conjectured that, for any chromatic polynomial

$$c_n z^n + \ldots + c_1 z, \quad (3)$$

there does not exist a $1 \leq p \leq q \leq r \leq n$ such that $|c_p| > |c_q|$ and $|c_q| < |c_r|$ (Skiena 1990, p. 221).

The CHROMATIC NUMBER of a graph gives the smallest number of colors with which a graph can be colored, and so is the smallest positive integer z such that $\pi_G(z) > 0$ (Skiena 1990, p. 211).

Chu-Vandermonde Identity

A special case of GAUSS'S THEOREM, with a being a NEGATIVE INTEGER $-n$:

$$ {}_2F_1(-n,\ b;\ c;\ 1) = \frac{(c-b)_n}{(c)_n}, $$

where ${}_2F_1(a,\ b;\ c;\ z)$ is a HYPERGEOMETRIC FUNCTION and $(a)_n$ is a POCHHAMMER SYMBOL (Bailey 1935, p. 3; Koepf 1998, p. 32). The identity is sometimes also called Vandermonde's theorem.

The identity

$$ (x+a)_n = \sum_{k=0}^{\infty} \binom{n}{k} (x)_k (a)_{n-k} $$

(Koepf 1998, p. 42), where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT and $(a)_n \equiv a(a-1)\cdots(a-n+1)$ is the POCHHAMMER SYMBOL is sometimes also known as the Chu-Vandermonde identity. (0) can be written as

$$ \binom{x+a}{n} = \sum_{k=0}^{n} \binom{x}{k} \binom{a}{n-k}, $$

which is sometimes known as VANDERMONDE'S CONVOLUTION FORMULA (Roman 1984). A special case gives the identity

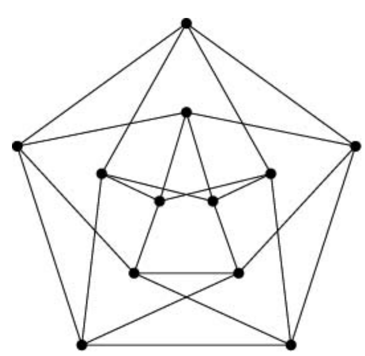
$$ \sum_{l=0}^{\max(k,\ n)} \binom{m}{k-l} \binom{n}{l} = \binom{m+n}{k}. $$

The identities

$$ \sum_{k=0}^{n} \binom{a}{k} \binom{b}{n-k} = \binom{a+b}{n} \tag{1} $$

$$ \sum_{k=0}^{n} \binom{n}{k} \binom{s}{t-k} = \binom{n+s}{t} \tag{2} $$

$$ \sum_{k=0}^{n} \binom{n}{k} \binom{s}{t+k} = \binom{n+s}{n+t} \tag{3} $$



are all special instances of the Chu-Vandermonde identity (Koepf 1998, p. 41).

COSINE INTEGRAL

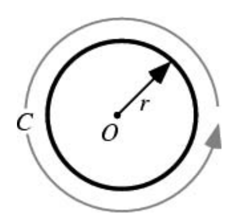
C-Infinity Function

A C^∞ function is a function that is DIFFERENTIABLE for all degrees of differentiation. For instance, $f(x) = e^{2x}$ is C^∞ because its nth derivative $f^{(n)}(x) = 2^n e^{2x}$ exists and is CONTINUOUS. All polynomials are C^∞. The reason for the notation is that C^k FUNCTIONS have k continuous derivatives.

C^∞ functions are also called "smooth" because neither they nor their derivatives have "corners," which would make their graph look somewhat rough. For example, $f(x) = |x^3|$ is not smooth.

There are special C^∞ functions which are very useful in analysis and geometry. For example, there are smooth functions called BUMP FUNCTIONS, which are smooth approximations to a CHARACTERISTIC FUNCTION. Typically, these functions require some CALCULUS to show that they are indeed C^∞.

Any ANALYTIC FUNCTION is smooth. But a smooth function is not necessarily analytic. For instance, an analytic function cannot be a BUMP FUNCTION. Consider the following function, whose TAYLOR SERIES at 0 is identically zero, yet the function is not zero:



$$f(x) = \begin{cases} 0 & \text{for } x \leq 0 \\ e^{-1/x} & \text{for } x > 0. \end{cases}$$

The function f goes to zero very quickly. One property of smooth functions is that they can look very different at different scales.

The set of smooth functions cannot be made into a BANACH SPACE, which makes some problems hard, but instead has the weaker structure of a FRÉCHET SPACE.

See also C-K FUNCTION, C-INFINITY TOPOLOGY, CALCULUS, DIFFERENTIAL TOPOLOGY, FRÉCHET SPACE, PARTITION OF UNITY, SARD'S THEOREM

Circle

A circle is the set of points equidistant from a given point O. The distance r from the CENTER is called the RADIUS, and the point O is called the CENTER. Twice the RADIUS is known as the DIAMETER $d = 2r$. The PERIMETER C of a circle is called the CIRCUMFERENCE, and is given by

$$C = \pi d = 2\pi r. \quad (1)$$

The angle a circle subtends from its center is a FULL ANGLE, equal to 360° or 2π RADIANS.

The circle is a CONIC SECTION obtained by the intersection of a CONE with a PLANE PERPENDICULAR to the CONE's symmetry axis. A circle is the degen-

erate case of an ELLIPSE with equal semimajor and semiminor axes (i.e., with ECCENTRICITY 0). The interior of a circle is called a DISK. The generalization of a circle to 3-D is called a SPHERE, and to n-D for $n \geq 4$ a HYPERSPHERE.

The region of intersection of two circles is called a LENS. The region of intersection of three symmetrically placed circles (as in a VENN DIAGRAM), in the special case of the center of each being located at the intersection of the other two, is called a REULEAUX TRIANGLE.

The PARAMETRIC EQUATIONS for a circle of RADIUS a are

$$x = a \cos t \tag{2}$$

$$y = a \sin t. \tag{3}$$

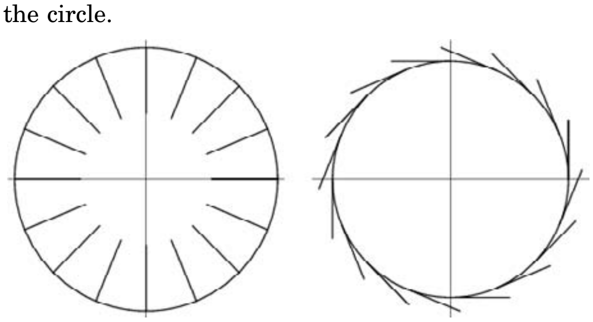
For a body moving uniformly around the circle,

$$x' = -a \sin t \tag{4}$$

$$y' = a \cos t, \tag{5}$$

and

$$x'' = -a \cos t \tag{6}$$



$$y'' = -a \sin t. \tag{7}$$

When normalized, the former gives the equation for the unit TANGENT VECTOR of the circle, $(-\sin t, \cos t)$. The circle can also be parameterized by the rational functions

$$x = \frac{1 - t^2}{1 + t^2} \tag{8}$$

$$y = \frac{2t}{1 + t^2}, \tag{9}$$

but an ELLIPTIC CURVE cannot. The following plots show a sequence of NORMAL and TANGENT VECTORS for the circle.

The ARC LENGTH s, CURVATURE κ, and TANGENTIAL ANGLE ϕ of the circle are

$$s(t) = \int ds = \int \sqrt{x'^2 + y'^2}\, dt = at \tag{10}$$

$$\kappa(t) = \frac{x'y'' - y'x''}{(x'^2 + y'^2)^{3/2}} = \frac{1}{a} \tag{11}$$

$$\phi(t) = \int \kappa(t)\, dt = \frac{t}{a}. \tag{12}$$

The CESÀRO EQUATION is

$$\kappa = \frac{1}{a}. \tag{13}$$

In POLAR COORDINATES, the equation of the circle has a particularly simple form.

$$r = a \tag{14}$$

is a circle of RADIUS a centered at ORIGIN,

$$r = 2a \cos\theta \tag{15}$$

is circle of RADIUS a centered at $(a, 0)$, and

$$r = 2a \sin\theta \tag{16}$$

is a circle of RADIUS a centered on $(0, a)$. In CARTESIAN COORDINATES, the equation of a circle of RADIUS a centered on (x_0, y_0) is

$$(x - x_0)^2 + (y - y_0)^2 = a^2. \tag{17}$$

In PEDAL COORDINATES with the PEDAL POINT at the center, the equation is

$$pa = r^2 \tag{18}$$

The circle having P_1P_2 as a diameter is given by

$$(x - x_1)(x - x_2) + (y - y_1)(y - y_2) = 0. \tag{19}$$

The equation of a circle passing through the three points (x_i, y_i) for $i = 1, 2, 3$ (the CIRCUMCIRCLE of the TRIANGLE determined by the points) is

$$\begin{vmatrix} x^2 + y^2 & x & y & 1 \\ x_1^2 + y_1^2 & x_1 & y_1 & 1 \\ x_2^2 + y_2^2 & x_2 & y_2 & 1 \\ x_3^2 + y_3^2 & x_3 & y_3 & 1 \end{vmatrix} = 0. \tag{20}$$

The CENTER and RADIUS of this circle can be identified by assigning coefficients of a QUADRATIC CURVE

$$ax^2 + cy^2 + dx + ey + f = 0, \tag{21}$$

where $a = c$ and $b = 0$ (since there is no xy cross term). COMPLETING THE SQUARE gives

$$a\left(x + \frac{d}{2a}\right)^2 + a\left(y + \frac{e}{2a}\right)^2 + f - \frac{d^2 + e^2}{4a} = 0. \tag{22}$$

The CENTER can then be identified as

$$x_0 = -\frac{d}{2a} \tag{23}$$

$$y_0 = -\frac{e}{2a} \tag{24}$$

and the RADIUS as

$$r = \sqrt{\frac{d^2+e^2}{4a^2} - \frac{f}{a}}, \tag{25}$$

where

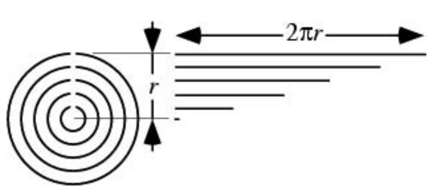
$$a = \begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{vmatrix} \tag{26}$$

$$d = -\begin{vmatrix} x_1^2+y_1^2 & y_1 & 1 \\ x_2^2+y_2^2 & y_2 & 1 \\ x_3^2+y_3^2 & y_3 & 1 \end{vmatrix} \tag{27}$$

$$e = \begin{vmatrix} x_1^2+y_1^2 & x_1 & 1 \\ x_2^2+y_2^2 & x_2 & 1 \\ x_3^2+y_3^2 & x_3 & 1 \end{vmatrix} \tag{28}$$

$$f = -\begin{vmatrix} x_1^2+y_1^2 & x_1 & y_1 \\ x_2^2+y_2^2 & x_2 & y_2 \\ x_3^2+y_3^2 & x_3 & y_3 \end{vmatrix} \tag{29}$$

Four or more points which lie on a circle are said to be CONCYCLIC. Three points are trivially concyclic since three noncollinear points determine a circle.

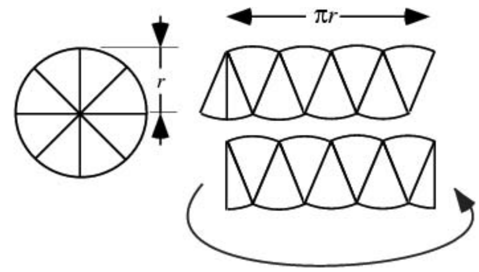


The CIRCUMFERENCE-to-DIAMETER ratio C/d for a circle is constant as the size of the circle is changed (as it must be since scaling a plane figure by a factor s increases its PERIMETER by s), and d also scales by s. This ratio is denoted π (PI), and has been proved TRANSCENDENTAL. With d the DIAMETER and r the RADIUS,

$$C = \pi d = 2\pi r. \tag{30}$$

Knowing C/d, we can then compute the AREA of the circle either geometrically or using CALCULUS. From CALCULUS,

$$A = \int_0^{2\pi} d\theta \int_0^r r\,dr = (2\pi)\left(\tfrac{1}{2} r^2\right) = \pi r^2. \tag{31}$$



Now for a few geometrical derivations. Using concentric strips, we have

As the number of strips increases to infinity, we are left with a TRIANGLE on the right, so

$$A = \tfrac{1}{2}(2\pi r)r = \pi r^2. \tag{32}$$

This derivation was first recorded by Archimedes in *Measurement of a Circle* (ca. 225 BC). If we cut the circle instead into wedges,

As the number of wedges increases to infinity, we are left with a RECTANGLE, so

$$A = (\pi r)r = \pi r^2. \tag{33}$$

Circle Bundle

A circle bundle $\pi : E \to M$ is a FIBER BUNDLE whose FIBERS $\pi^{-1}(x)$ are circles. It may also have the structure of a PRINCIPAL BUNDLE if there is an action of $SO(2)$ that preserves the fibers, and is locally trivial. That is, if every point has a TRIVIALIZATION $U \times \mathbb{S}^1$ such that the action of $SO(2)$ on $\mathbb{S}^1$ is the usual one.

See also BUNDLE, GROUP ACTION, PRINCIPAL BUNDLE

Circle Caustic

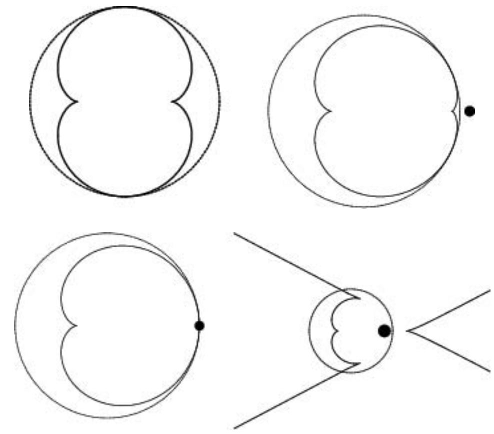
Consider a point light source located at a point $(\mu, 0)$. The CATACAUSTIC of a unit CIRCLE for the light at $\mu = \infty$ is the NEPHROID

$$x = \tfrac{1}{4}[3\cos t - \cos(3t)] \tag{1}$$

$$y = \tfrac{1}{4}[3\sin t - \sin(3t)]. \tag{2}$$

The CATACAUSTIC for the light at a finite distance $\mu > 1$ is the curve

$$x = \frac{\mu(1 - 3\mu\cos t + 2\mu\cos^3 t)}{-(1 + 2\mu^2) + 3\mu\cos t} \tag{3}$$



$$y = \frac{2\mu^2 \sin^3 t}{1 + 2\mu^2 - 3\mu\cos t}, \tag{4}$$

and for the light on the CIRCUMFERENCE of the CIRCLE $\mu = 1$ is the CARDIOID

$$x = \tfrac{2}{3}\cos t(1 + \cos t) - \tfrac{1}{3} \tag{5}$$

$$y = \tfrac{2}{3}\sin t(1 + \cos t). \tag{6}$$

If the point is inside the circle, the catacaustic is a discontinuous two-part curve. These four cases are illustrated below.

The CATACAUSTIC for PARALLEL rays crossing a CIRCLE is a CARDIOID.

Circle Covering by Arcs

The probability $P(a, n)$ that n random arcs of angular size a cover the circumference of a circle completely (for a circle with unit circumference) is

$$P(a, n) = \sum_{k=0}^{\lfloor 1/a \rfloor} (-1)^k \binom{n}{k} (1-ka)^{n-1},$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION (Solomon 1978, p. 75). This was first given correctly by Stevens (1939), although partial results were obtains by Whitworth (1897), Baticle (1935), Garwood (1940), Darling (1953), and Shepp (1972).

The probability that n arcs leave exactly l gaps is given by

$$P_{l \text{ gaps}}(a, n) = \binom{n}{l} \sum_{j=1}^{k} (-1)^{j-l} \binom{n-l}{j-l} (1-ja)^{n-1}$$

(Stevens 1939; Solomon 1978, p. 76).

Circle Cutting

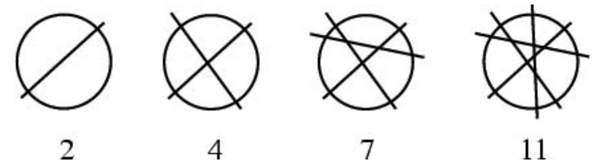
CIRCLE DIVISION BY CHORDS, CIRCLE DIVISION BY LINES

Circle Division by Chords

A related problem, sometimes called Moser's circle problem, is to find the number of pieces into which a CIRCLE is divided if n points on its CIRCUMFERENCE are joined by CHORDS with no three CONCURRENT. The answer is

$$g(n) = \binom{n}{4} + \binom{n}{2} + 1 \tag{1}$$

$$= \tfrac{1}{24}(n^4 - 6n^3 + 23n^2 - 18n + 24), \tag{2}$$



(Yaglom and Yaglom 1987, Guy 1988, Conway and Guy 1996, Noy 1996), where $\binom{n}{m}$ is a BINOMIAL COEFFICIENT. The first few values are 1, 2, 4, 8, 16, 31, 57, 99, 163, 256, ... (Sloane's A000127). This sequence demonstrates the danger in making assumptions based on limited trials. While the series starts off like 2^{n-1}, it begins differing from this GEOMETRIC SERIES at $n = 6$.

Circle Division by Lines

Determining the maximum number of pieces in which it is possible to divide a CIRCLE for a given number of cuts is called the circle cutting, or sometimes PANCAKE CUTTING, problem. The minimum number is always $n + 1$, where n is the number of cuts, and it is

always possible to obtain any number of pieces between the minimum and maximum. The first cut creates 2 regions, and the nth cut creates n new regions, so

$$f(1) = 2 \quad (1)$$

$$f(2) = 2 + f(1) \quad (2)$$

$$f(n) = n + f(n-1). \quad (3)$$

Therefore,

$$f(n) = n + [(n-1) + f(n-2)]$$
$$= n + (n-1) + \ldots + 2 + f(1) = f(1) + \sum_{k=2}^{n} kf(1)$$
$$= 2 + \tfrac{1}{2}(n+2)(n-1) = \tfrac{1}{2}(n^2 + n + 2). \quad (4)$$

Evaluating for $n = 1, 2, \ldots$ gives 2, 4, 7, 11, 16, 22, ... (Sloane's A000124). This is equivalent to the maximal number of regions into which a PLANE can be cut by n lines.

Circle Evolute

$$x = \cos t \quad x' = -\sin t \quad x'' = -\cos t \quad (1)$$

$$y = \sin t \quad y' = \cos t \quad y'' = -\sin t, \quad (2)$$

so the RADIUS OF CURVATURE is

$$R = \frac{(x'^2 + y'^2)^{3/2}}{y''x' - x''y'} = \frac{(\sin^2 t + \cos^2 t)^{3/2}}{(-\sin t)(-\sin t) - (-\cos t)\cos t}$$
$$= 1, \quad (3)$$

and the TANGENT VECTOR is

$$\hat{\mathbf{T}} = \begin{bmatrix} -\sin t \\ \cos t \end{bmatrix}. \quad (4)$$

Therefore,

$$\cos \tau = \hat{\mathbf{T}} \cdot \hat{\mathbf{x}} = -\sin t \quad (5)$$

$$\sin \tau = \hat{\mathbf{T}} \cdot \hat{\mathbf{y}} = \cos t, \quad (6)$$

so

$$\xi(t) = x - R \sin \tau = \cos t - 1 \cdot \cos t = 0 \quad (7)$$

$$\eta(t) = y + R \cos \tau = \sin t + 1 \cdot (-\sin t) = 0, \quad (8)$$

and the EVOLUTE degenerates to a POINT at the ORIGIN.

Circle Inscribing

If r is the INRADIUS of a CIRCLE inscribed in a RIGHT TRIANGLE with sides a and b and HYPOTENUSE c, then

$$r = \tfrac{1}{2}(a + b - c).$$

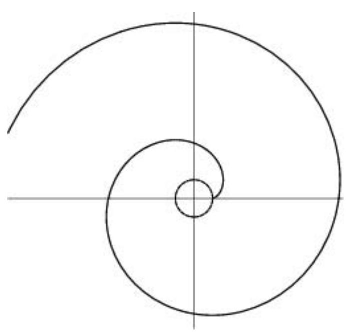
A SANGAKU PROBLEM dated 1803 from the Gumma Prefecture asks to construct the figure consisting of a circle centered at O, a second smaller circle centered at O_2 tangent to the first, and an ISOSCELES TRIANGLE whose base AB completes the diameter of the larger circle through the smaller XB. Now inscribe a third circle with center O_3 inside the large circle, outside the small one, and on the side of a leg of the triangle. It then follows that the line $O_3A \perp XB$. To find the explicit position and size of the circle, let the circle O have radius 1/2 and be centered at (0, 0) and let the circle O_2 have diameter $0 < r < 1$. Then solving the simultaneous equations

$$\left(\tfrac{1}{2}r + a\right)^2 = \left(\tfrac{1}{2}r\right)^2 + y^2 \quad (1)$$

$$\left(\tfrac{1}{2} - a\right)^2 = \left(r - \tfrac{1}{2}\right)^2 + y^2 \quad (2)$$

for a and y gives

$$a = \frac{r(1-r)}{1+r} \tag{3}$$



$$y = \frac{r\sqrt{2(1-r)}}{1+r}. \tag{4}$$

Rothman, T. "Japanese Temple Geometry." *Sci. Amer.* **278**, 85–1, May 1998.

Circle Involute

First studied by Huygens when he was considering clocks without pendula for use on ships at sea. He used the circle involute in his first pendulum clock in an attempt to force the pendulum to swing in the path of a cycloid. For a circle with $a = 1$, the parametric equations of the circle and their derivatives are given by

$$x = \cos t \quad x' = -\sin t \quad x'' = -\cos t \tag{1}$$

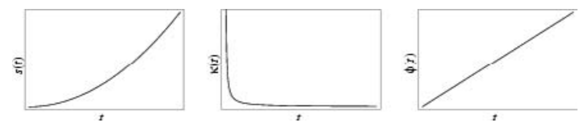
$$y = \sin t \quad y' = \cos t \quad y'' = -\sin t. \tag{2}$$

The tangent vector is

$$\hat{\mathbf{T}} = \begin{bmatrix} -\sin t \\ \cos t \end{bmatrix} \tag{3}$$

and the arc length along the circle is

$$s = \int \sqrt{x'^2 + y'^2}\, dt = \int dt = t, \tag{4}$$



so the involute is given by

$$\mathbf{r}_i = \mathbf{r} - s\hat{\mathbf{T}} = \begin{bmatrix} \cos t \\ \sin t \end{bmatrix} - t \begin{bmatrix} -\sin t \\ \cos t \end{bmatrix} = \begin{bmatrix} \cos t + t\sin t \\ \sin t - t\cos t \end{bmatrix}, \tag{5}$$

or

$$x = a(\cos t + t\sin t) \tag{6}$$

$$y = a(\sin t - t\cos t). \tag{7}$$

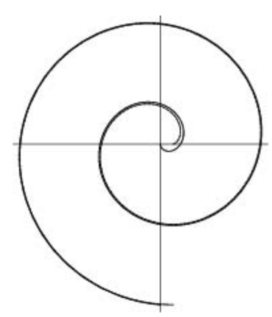
The arc length, curvature, and tangential angle are

$$s = \int ds = \int \sqrt{x'^2 + y'^2}\, dt = \tfrac{1}{2} a t^2 \tag{8}$$

$$\kappa = \frac{1}{at} \tag{9}$$

$$\phi = t. \tag{10}$$

The Cesàro equation is



$$\kappa = \frac{1}{\sqrt{as}}. \tag{11}$$

Circle Involute Pedal Curve

The pedal curve of circle involute

$$f = \cos t + t\sin t$$

$$g = \sin t - t\cos t$$

with the center as the pedal point is the Archi-

MEDES' SPIRAL

$$x = t \sin t$$

$$y = -t \cos t.$$

Circle Lattice Points

For every POSITIVE INTEGER n, there exists a CIRCLE which contains exactly n lattice points in its interior. H. Steinhaus proved that for every POSITIVE INTEGER n, there exists a CIRCLE of AREA n which contains exactly n lattice points in its interior.

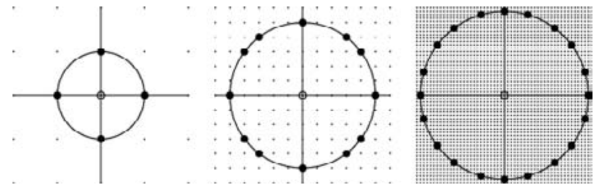
SCHINZEL'S THEOREM shows that for every POSITIVE INTEGER n, there exists a CIRCLE in the PLANE having exactly n LATTICE POINTS on its CIRCUMFERENCE. The theorem also explicitly identifies such "SCHINZEL CIRCLES" as

$$\begin{cases} \left(x-\frac{1}{2}\right)^2+y^2=\frac{1}{4}\,5^{k-1} & \text{for } n=2k \\ \left(x-\frac{1}{3}\right)^2+y^2=\frac{1}{9}\,5^{2k} & \text{for } n=2k+1. \end{cases} \tag{1}$$

Note, however, that these solutions do not necessarily have the smallest possible RADIUS. For example, while the SCHINZEL CIRCLE centered at (1/3, 0) and with RADIUS 625/3 has nine lattice points on its CIRCUMFERENCE, so does the CIRCLE centered at (1/3, 0) with RADIUS 65/3.

Let r be the smallest INTEGER RADIUS of a CIRCLE centered at the ORIGIN (0, 0) with $L(r)$ LATTICE POINTS. In order to find the number of lattice points of the CIRCLE, it is only necessary to find the number in the first octant, i.e., those with $0 \leq y \leq \lfloor r/\sqrt{2} \rfloor$, where $\lfloor z \rfloor$ is the FLOOR FUNCTION. Calling this $N(r)$, then for $r \geq 1$, $L(r) = 8N(r) - 4$, so $L(r) \equiv 4 \pmod 8$. The multiplication by eight counts all octants, and the subtraction by four eliminates points on the axes which the multiplication counts twice. (Since $\sqrt{2}$ is IRRATIONAL, a mid-arc point is never a LATTICE POINT.)

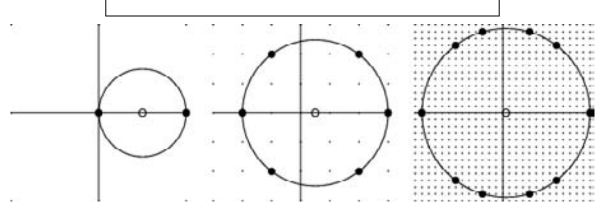
GAUSS'S CIRCLE PROBLEM asks for the number of lattice points *within* a CIRCLE of RADIUS r



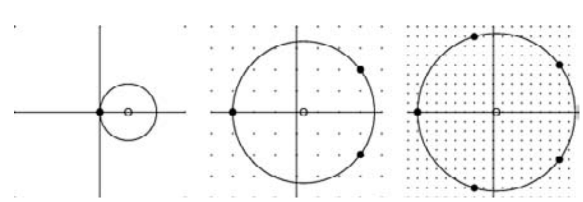
$$N(r) = 1 + 4\lfloor r \rfloor + 4 \sum_{i=1}^{\lfloor r \rfloor} \left\lfloor \sqrt{r^2 - i^2} \right\rfloor. \tag{2}$$

Gauss showed that

$$N(r) = \pi r^2 + E(r), \tag{3}$$



where



$$|E(r)| \leq 2\sqrt{2}\pi r. \tag{4}$$

The number of lattice points on the CIRCUMFERENCE of circles centered at (0, 0) with radii 0, 1, 2, ... are 1, 4, 4, 4, 4, 12, 4, 4, 4, 4, 12, 4, 4, ... (Sloane's A046109). The following table gives the smallest RADIUS $r \leq 390,800$ for a circle centered at (0, 0) having a given number of LATTICE POINTS $L(r)$ (Sloane's A046112). Note that the high-water mark radii are always multiples of five.

$L(r)$	r	$L(r)$	r
1	0	108	1,105
4	1	132	40,625
12	5	140	21,125
20	25	156	203,125
28	125	180	5,525
36	65	196	274,625
44	3,125	252	27,625
52	15,625	300	71,825
60	325	324	32,045
68	390,625	420	359,125
76	$\leq 1,953,125$	540	160,225
84	1,625		
92	$\leq 48,828,125$		
100	4,225		

If the CIRCLE is instead centered at (1/2, 0), then the CIRCLES of RADII 1/2, 3/2, 5/2, ... have 2, 2, 6, 2, 2, 2, 6,

6, 6, 2, 2, 2, 10, 2, ... (Sloane's A046110) on their CIRCUMFERENCES. If the CIRCLE is instead centered at (1/3, 0), then the number of lattice points on the CIRCUMFERENCE of the CIRCLES of RADIUS 1/3, 2/3, 4/3, 5/3, 7/3, 8/3, ... are 1, 1, 1, 3, 1, 1, 3, 1, 3, 1, 1, 3, 1, 3, 1, 1, 5, 3, ... (Sloane's A046111).

Let

1. a_n be the RADIUS of the CIRCLE centered at (0, 0) having $8n+4$ lattice points on its CIRCUMFERENCE,
2. $b_n/2$ be the RADIUS of the CIRCLE centered at (1/2, 0) having $4n+2$ lattice points on its CIRCUMFERENCE,
3. $c_n/3$ be the RADIUS of CIRCLE centered at (1/3, 0) having $2n+1$ lattice points on its CIRCUMFERENCE.

Then the sequences $\{a_n\}$, $\{b_n\}$, and $\{c_n\}$ are equal, with the exception that $b_n=0$ if $2|n$ and $c_n=0$ if $3|n$. However, the sequences of *smallest* radii having the above numbers of lattice points are equal in the three cases and given by 1, 5, 25, 125, 65, 3125, 15625, 325, ... (Sloane's A046112).

KULIKOWSKI'S THEOREM states that for every POSITIVE INTEGER n, there exists a 3-D SPHERE which has exactly n LATTICE POINTS on its surface. The SPHERE is given by the equation

$$(x-a)^2+(y-b)^2+(z-\sqrt{2})^2=c^2+2,$$

where a and b are the coordinates of the center of the so-called SCHINZEL CIRCLE and c is its RADIUS (Honsberger 1973).

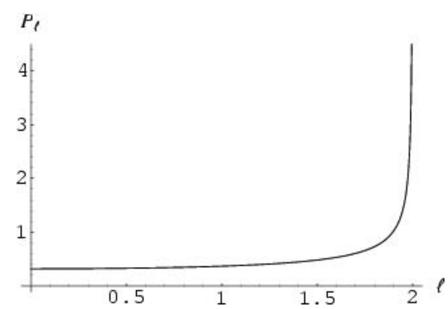
Circle Lattice Theorem

GAUSS'S CIRCLE PROBLEM

Circle Line Picking



Given a UNIT CIRCLE, pick two points at random on its circumference, forming a CHORD. Without loss of generality, the first point can be taken as (1, 0), and the second by $(\cos\theta, \sin\theta)$, with $\theta \in [0, \pi]$ (by symmetry, the range can be limited to π instead of 2π). The distance s between the two points is then

$$s(\theta)=\sqrt{2-2\cos\theta}=2|\sin(\tfrac{1}{2}\theta)|. \tag{1}$$

The average distance is then given by

$$\bar{s}=\frac{\int_0^\pi s(\theta)\,d\theta}{\int_0^\pi d\theta}=\frac{4}{\pi}. \tag{2}$$

The probability function P_s is obtained from

$$P_s=\left|\frac{d\theta}{ds}\right|P_\theta=\frac{1}{\pi}\frac{1}{\sqrt{1-(\frac{1}{2}s)^2}}. \tag{3}$$

The RAW MOMENTS are then

$$\mu'_n=\frac{\int_0^\pi [2\sin(\frac{1}{2}\theta)]^n\,d\theta}{\int_0^\pi d\theta} \tag{4}$$

$$=\int_0^2 \frac{s^n}{\pi\sqrt{1-(\frac{1}{2}s)^2}} \tag{5}$$

$$=\frac{2^n\Gamma(\frac{1}{2}(1+n))}{\sqrt{\pi}\,\Gamma(1+\frac{1}{2}n)}, \tag{6}$$

giving the first few as

$$\mu_2' = 2 \quad (7)$$

$$\mu_3' = \frac{32}{3\pi} \quad (8)$$

$$\mu_4' = 6. \quad (9)$$

The CENTRAL MOMENTS are

$$\mu_2 = 2 - \frac{16}{\pi^2} \quad (10)$$

$$\mu_3 = \frac{8(48 - 5\pi^2)}{3\pi^3} \quad (11)$$

$$\mu_4 = 6 + \frac{64(\pi^2 - 36)}{3\pi^4}, \quad (12)$$

giving the SKEWNESS and KURTOSIS as

$$\gamma_1 = \frac{2\sqrt{2}(48 - 5\pi^2)}{3(\pi^2 - 8)^{3/2}} \quad (13)$$

$$\gamma_2 = \frac{-9\pi^4 + 320\pi^2 - 2304}{6(\pi^2 - 8)^2}. \quad (14)$$

BERTRAND'S PROBLEM asks for the PROBABILITY that a CHORD drawn at random on a CIRCLE of RADIUS r has length $\geq r$.

See also BALL LINE PICKING, BERTRAND'S PROBLEM, CIRCLE COVERING BY ARCS, CIRCLE TRIANGLE PICKING, DISK LINE PICKING

Circle Map

A 1-D MAP which maps a CIRCLE onto itself

$$\theta_{n+1} = \theta_n + \Omega - \frac{K}{2\pi} \sin(2\pi\theta_n), \quad (1)$$

where θ_{n+1} is computed mod 1 and K is a constant. Note that the circle map has two parameters: Ω and K. Ω can be interpreted as an externally applied frequency, and K as a strength of nonlinearity. The 1-D JACOBIAN is

$$\frac{\partial\theta_{n+1}}{\partial\theta_n} = 1 - K\cos(2\pi\theta_n), \quad (2)$$

so the circle map is not AREA-PRESERVING. It is related to the STANDARD MAP

$$I_{n+1} = I_n + \frac{K}{2\pi} \sin(2\pi\theta_n) \quad (3)$$

$$\theta_{n+1} = \theta_n + I_{n+1}, \quad (4)$$

for I and θ computed mod 1. Writing θ_{n+1} as

$$\theta_{n+1} = \theta_n + I_n + \frac{K}{2\pi} \sin(2\pi\theta_n) \quad (5)$$

gives the circle map with $I_n = \Omega$ and $K = -K$. The unperturbed circle map has the form

$$\theta_{n+1} = \theta_n + \Omega. \quad (6)$$

If Ω is RATIONAL, then it is known as the map WINDING NUMBER, defined by

$$\Omega = W \equiv \frac{p}{q}, \quad (7)$$

and implies a periodic trajectory, since θ_n will return to the same point (at most) every q ORBITS. If Ω is IRRATIONAL, then the motion is quasiperiodic. If K is NONZERO, then the motion may be periodic in some finite region surrounding each RATIONAL Ω. This execution of periodic motion in response to an IRRATIONAL forcing is known as MODE LOCKING.

If a plot is made of K vs. Ω with the regions of periodic MODE-LOCKED parameter space plotted around RATIONAL Ω values (WINDING NUMBERS), then the regions are seen to widen upward from 0 at $K = 0$ to some finite width at $K = 1$. The region surrounding each RATIONAL NUMBER is known as an ARNOLD TONGUE. At $K = 0$, the ARNOLD TONGUES are an isolated set of MEASURE zero. At $K = 1$, they form a CANTOR SET of DIMENSION $d \approx 0.08700$. For $K > 1$, the tongues overlap, and the circle map becomes noninvertible.

Let Ω_n be the parameter value of the circle map for a cycle with WINDING NUMBER $W_n = F_n/F_{n+1}$ passing with an angle $\theta = 0$, where F_n is a FIBONACCI NUMBER. Then the parameter values Ω_n accumulate at the rate

$$\delta \equiv \lim_{n\to\infty} \frac{\Omega_n - \Omega_{n-1}}{\Omega_{n+1} - \Omega_n} = -2.833 \quad (8)$$

(Feigenbaum *et al.* 1982).

Circle Method

A method employed by Hardy, Ramanujan, and Littlewood to solve many asymptotic problems in ADDITIVE NUMBER THEORY, particularly in deriving an asymptotic formula for the PARTITION FUNCTION P. The circle method proceeds by choosing a circular CONTOUR satisfying certain technical properties (Apostol 1997). The method was modified by Rade-

macher using a different contour in his derivative of the exact convergent formula for the PARTITION FUNCTION P.

See also PARTITION FUNCTION P

Circle Negative Pedal Curve

The NEGATIVE PEDAL CURVE of a circle is an ELLIPSE if the PEDAL POINT is inside the CIRCLE, and a HYPERBOLA if the PEDAL POINT is outside the CIRCLE.

Circle Notation

A NOTATION for LARGE NUMBERS due to Steinhaus (1983). In circle notation, $\textcircled{n}$ is defined as n in n SQUARES, where numbers written inside squares (and triangles) are interpreted in terms of STEINHAUS-MOSER NOTATION. The particular number known as the MEGA is then defined as follows (correcting the typographical error of Steinhaus).

See also MEGA, MEGISTRON, STEINHAUS-MOSER NOTATION

Circle Order

A POSET P is a circle order if it is ISOMORPHIC to a SET of DISKS ordered by containment.

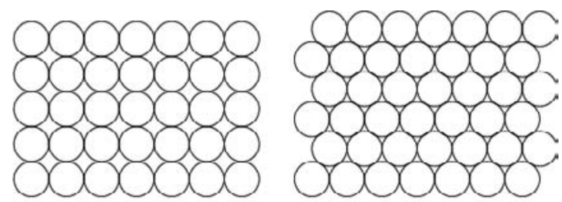
See also ISOMORPHIC POSETS, PARTIALLY ORDERED SET

Circle Orthotomic

The ORTHOTOMIC of the CIRCLE represented by

$$x = \cos t \tag{1}$$

$$y = \sin t \tag{2}$$



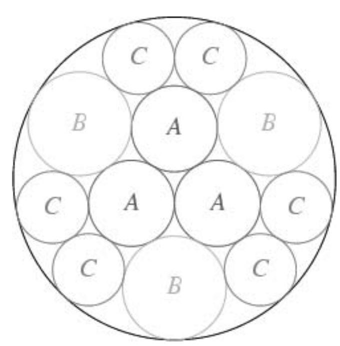
with a source at (x, y) is

$$x = x\cos(2t) - y\sin(2t) + 2\sin t \tag{3}$$

$$y = -x\sin(2t) - y\cos(2t) + 2\cos t. \tag{4}$$

Circle Packing

A circle packing is an arrangement of circles inside a given boundary such that no two overlap and some (or all) of them are mutually tangent. The generalization to spheres is called a SPHERE PACKING. TESSELLATIONS of regular polygons correspond to particular circle packings (Williams 1979, pp. 35–1). There is a well developed theory of circle packing in the context of discrete conformal mapping (Stephenson).



square packing *hexagonal packing*

The densest packing of circles in the PLANE is the hexagonal lattice of the bee's honeycomb (right figure; Steinhaus 1983, p. 202), which has a PACKING DENSITY of

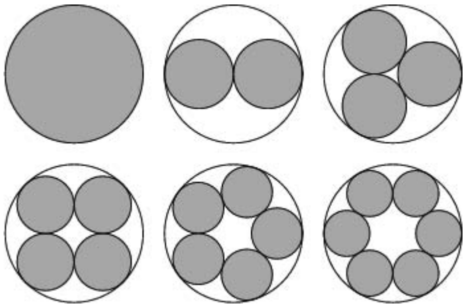
$$\eta_h = \tfrac{1}{6}\pi\sqrt{3} \approx 0.9068996821 \tag{1}$$

(Wells 1986, p. 30). Gauss proved that the hexagonal lattice is the densest plane *lattice* packing, and in 1940, L. Fejes Tóth proved that the hexagonal lattice is indeed the densest of *all* possible plane packings.

Wells (1991, pp. 30–1) considers the maximum size possible for n identical circles packed on the surface of a UNIT SPHERE.

Using discrete conformal mapping, the radii of the circles in the above packing inside a UNIT CIRCLE can be determined as roots of the polynomial equations

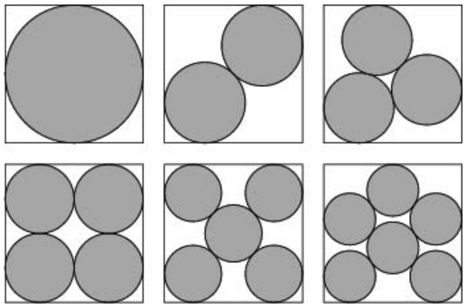
$$a^6 + 378a^5 + 3411a^4 - 8964a^3 - 10233a^2 + 3402a - 27 = 0 \tag{2}$$



$$169b^6+24978b^5+2307b^4-14580b^3+3375b^2+162b$$
$$-27=0 \quad (3)$$
$$c^6+438c^5+19077c^4-15840c^3-360c^2+2592c-432$$
$$=0 \quad (4)$$

with

$$a \approx 0.266746 \quad (5)$$
$$b \approx 0.321596 \quad (6)$$
$$c \approx 0.223138. \quad (7)$$

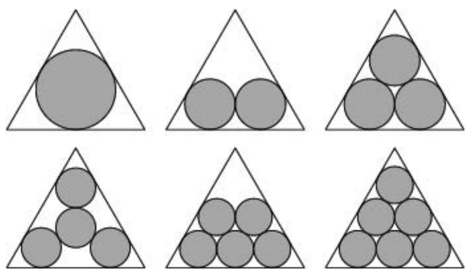


The following table gives the packing densities η for the circle packings corresponding to the regular and semiregular plane tessellations (Williams 1979, p. 49).

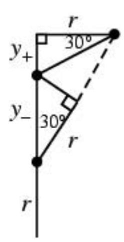
TESSELLATION	η exact	η approx.
{3, 6}	$\frac{1}{12}\sqrt{12}\pi$	0.9069
{4, 4}	$\frac{1}{4}\pi$	0.7854
{6, 3}	$\frac{1}{9}\sqrt{3}\pi$	0.6046
$3^2.4^2$	$(2-\sqrt{3})\pi$	0.8418
$3^2.4.3.4$	$(2-\sqrt{3})\pi$	0.8418
3.6.3.6	$\frac{1}{8}\sqrt{3}\pi$	0.6802
$3^4.6$	$\frac{1}{7}\sqrt{2}\pi$	0.7773
3.12^2	$(7\sqrt{3}-12)\pi$	0.3907
4.8^2	$(3-2\sqrt{2})\pi$	0.5390
3.4.6.4	$\frac{1}{3}(2\sqrt{3}-3)\pi$	0.7290
3.4.6.4	$\frac{1}{3}(2\sqrt{3}-3)\pi$	0.4860

Solutions for the smallest diameter CIRCLES into which n UNIT CIRCLES can be packed have been proved optimal for $n=1$ through 10 (Kravitz 1967). The best known results are summarized in the following table, and the first few cases are illustrated above (Friedman).

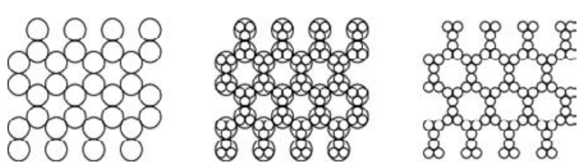
n	d exact	d approx.
1	1	1.00000
2	2	2.00000
3	$1+\frac{2}{3}\sqrt{3}$	2.15470...
4	$1+\sqrt{2}$	2.41421...
5	$1+\sqrt{2(1+1/\sqrt{5})}$	2.70130...
6	3	3.00000
7	3	3.00000
8	$1+\csc(\pi/7)$	3.30476...
9	$1+\sqrt{2(2+\sqrt{2})}$	3.61312...
10		3.82...
11		
12		4.02...



The following table gives the diameters d of circles giving the densest known packings of n equal circles packed inside a UNIT SQUARE, the first few of which are illustrated above (Friedman). All $n=1$ to 20 solutions (in addition to all solutions $n=k^2$) have been proved optimal (Friedman). Peikert (1994) uses a normalization in which the *centers* of n circles of diameter m are packed into a square of side length 1. Friedman lets the circles have unit radius and gives the smallest square side length s. A tabulation of analytic s and diagrams for $n=1$ to 25 circles is given by Friedman. Coordinates for optimal packings are given by Nurmela and Östergård.



n	d	$\approx d$	m	$\approx m$
1	1	1.000000		
2	$\frac{2}{2+\sqrt{2}}$	0.585786	$\sqrt{2}$	1.414214
3	$\frac{4}{4+\sqrt{2}+\sqrt{6}}$	0.508666	$\sqrt{6}-\sqrt{2}$	1.035276
4	$\frac{1}{2}$	0.500000	1	1.000000



5	$\sqrt{2}-1$	0.414214	$\frac{1}{2}\sqrt{2}$	0.707107
6	$\frac{1}{23}(6\sqrt{13}-13)$	0.375361	$\frac{1}{6}\sqrt{13}$	0.600925
7	$\frac{2}{13}(4-\sqrt{3})$	0.348915	$4-2\sqrt{3}$	0.535898
8	$\frac{2}{2+\sqrt{2}+\sqrt{6}}$	0.341081	$\frac{1}{2}(\sqrt{6}-\sqrt{2})$	0.517638
9	$\frac{1}{3}$	0.333333	$\frac{1}{2}$	0.500000
10		0.296408		0.421280

The smallest SQUARE into which two UNIT CIRCLES, one of which is split into two pieces by a chord, can be packed is not known (Goldberg 1968, Ogilvy 1990).

The best known packings of circles into an equilateral triangle are shown above for the first few cases (Friedman).

A rigid packing of circles can be obtained from a hexagonal tessellation by removing the centers of a hexagonal web, then replacing each remaining circle with three equal inscribed circles (appropriately oriented), as illustrated above (Meschkowski 1966, Wells 1991). If the original circles have unit radius, the lengths r, y_-, and y_+ can be obtained by solving

$$r = y_- \cos 30°, \tag{8}$$

$$r + y_- = 1 \tag{9}$$

$$y_+ = r \tan 30°, \tag{10}$$

giving

$$r = 2\sqrt{3} - 3 \tag{11}$$

$$y_- = 4 - 2\sqrt{3} \tag{12}$$

$$y_+ = 2 - \sqrt{3}. \tag{13}$$

The resulting circles cover a fraction

$$\eta = \eta_h \left(\frac{2}{3} \frac{3\pi r^2}{\pi 1^2} \right) = (7\sqrt{3} - 12)\pi \approx 0.390675 \tag{14}$$

of the plane, believed to be the smallest possible for a rigid packing of circles (Wells 1991).

Circle Pedal Curve

The PEDAL CURVE of a CIRCLE is a CARDIOID if the PEDAL POINT is taken on the CIRCUMFERENCE,

and otherwise a LIMAÇON.

Circle Point Picking

A uniform distribution of points on the CIRCUMFERENCE of a UNIT CIRCLE can be obtained by picking two numbers x_1, x_2 from a UNIFORM DISTRIBUTION on $(-1, 1)$, and rejecting pairs with $x_1^2 + x_2^2 \geq 1$. From the remaining points, the DOUBLE-ANGLE FORMULAS then imply that the points with CARTESIAN COORDINATES

$$x = \frac{x_1^2 - x_2^2}{x_1^2 + x_2^2}$$

$$y = \frac{2x_1x_2}{x_1^2 + x_2^2}$$

have the desired distribution (von Neumann 1951, Cook 1957). This method can also be extended to SPHERE POINT PICKING (Cook 1957). The plots above show the distribution of points for 50, 100, and 500 initial points (where the counts refer to the number of points before throwing away).

See also CIRCLE COVERING BY ARCS, DISK POINT PICKING, SPHERE POINT PICKING

Circle Quadrature

CIRCLE SQUARING

Circle Radial Curve

The RADIAL CURVE of a unit CIRCLE from a RADIAL POINT $(x, 0)$ is another CIRCLE with PARAMETRIC EQUATIONS

$$x(t) = x - \cos t$$
$$y(t) = -\sin t.$$

Circle Squaring

Construct a SQUARE equal in AREA to a CIRCLE using only a STRAIGHTEDGE and COMPASS. This was one of the three GEOMETRIC PROBLEMS OF ANTIQUITY, and was perhaps first attempted by Anaxagoras. It was finally proved to be an impossible problem when PI was proven to be TRANSCENDENTAL by Lindemann in 1882.'

However, approximations to circle squaring are given by constructing lengths close to $\pi = 3.1415926\ldots$. Ramanujan (1913–4), Olds (1963), Gardner (1966, pp. 92–3), and (Bold 1982, p. 45) give geometric constructions for $355/113 = 3.1415929\ldots$. Dixon (1991) gives constructions for $6/5(1+\phi) = 3.141640\ldots$ and $\sqrt{40/3 - 2\sqrt{3}} = 3.141533\ldots$ (KOCHANSKY'S APPROXIMATION).

While the circle cannot be squared in EUCLIDEAN SPACE, it *can* in GAUSS-BOLYAI-LOBACHEVSKY SPACE (Gray 1989).

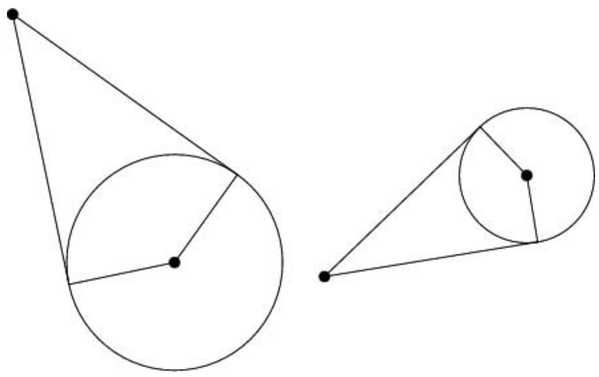
Circle Strophoid

The STROPHOID of a CIRCLE with pole at the center and fixed point on the CIRCUMFERENCE is a FREETH'S NEPHROID.

Circle Tangents



Given the above figure, $GE = FH$, since

$$AB = AG + GB = GE + GF = GE + (GE + EF) = 2GE + EF$$

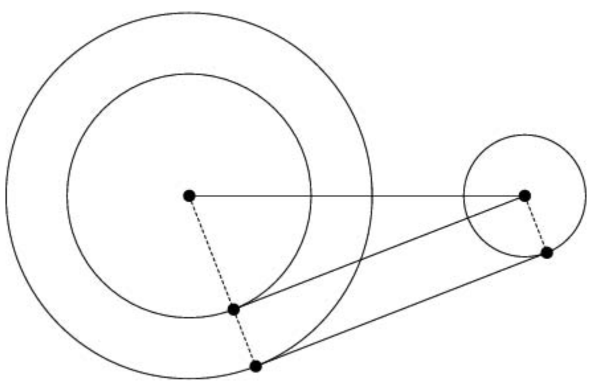
$$CD = CH + HD = EH + FH = FH + (FH + EF) = EF + 2FH.$$

Because $AB = CD$, it follows that $GE = FH$.

The line tangent to a CIRCLE of RADIUS a centered at (x, y)

$$x' = x + a \cos t$$

$$y' = y + a \sin t$$



through (0, 0) can be found by solving the equation

$$\begin{bmatrix} x + a \cos t \\ y + a \sin t \end{bmatrix} \cdot \begin{bmatrix} a \cos t \\ a \sin t \end{bmatrix} = 0,$$

giving

$$t = \pm \cos^{-1}\left(\frac{-ax \pm y\sqrt{x^2 + y^2 - a^2}}{x^2 + y^2} \right).$$

Two of these four solutions give tangent lines, as illustrated above, and the lengths of these lines are equal (Casey 1888, p. 29).

A line tangent to two given circles at centers $\mathbf{r}_1$ and $\mathbf{r}_2$ of radii a_1 and $a_2 < a_1$ may be constructed by constructing the tangent to the single circle of radius $a_1 - a_2$ centered at $\mathbf{r}_1$ and through $\mathbf{r}_2$, then translating this line along the radius through $\mathbf{r}_1$ a distance a_2 until it falls on the original two circles (Casey 1888, pp. 31–2).

Circle Triangle Picking

Select three points at random on a unit CIRCLE. Find the distribution of possible areas.

The first point can be assigned coordinates (1, 0) without loss of generality. Call the central angles from the first point to the second and third θ_1 and θ_2. The range of θ_1 can be restricted to $[0, \pi]$ because of symmetry, but θ_2 can range from $[0, 2\pi)$. Then

$$A(\theta_1, \theta_2) = 2|\sin(\tfrac{1}{2}\theta_1)\sin(\tfrac{1}{2}\theta_2)\sin[\tfrac{1}{2}(\theta_1 - \theta_2)]|, \tag{1}$$

so

$$\bar{A} = \frac{\int_0^\pi \int_0^{2\pi} A(\theta_1, \theta_2)\, d\theta_2\, d\theta_1}{C}, \tag{2}$$

where

$$C \equiv \int_0^\pi \int_0^{2\pi} d\theta_2\, d\theta_1 = 2\pi^2. \tag{3}$$

Therefore,

$$\bar{A} = \frac{2}{2\pi^2} \int_0^\pi \int_0^{2\pi} |\sin(\tfrac{1}{2}\theta_1)\sin(\tfrac{1}{2}\theta_2)\sin[\tfrac{1}{2}(\theta_1 - \theta_2)]|\, d\theta_2\, d\theta_1$$

$$= \frac{1}{\pi^2} \int_0^\pi \sin(\tfrac{1}{2}\theta_1)\left[\int_0^{2\pi} \sin(\tfrac{1}{2}\theta_2)|\sin[\tfrac{1}{2}(\theta_2 - \theta_1)]|\, d\theta_2\right] d\theta_1$$

$$= \frac{1}{\pi^2} \underset{\theta_2 - \theta_1 > 0}{\int_0^\pi \int_0^{2\pi}} \sin(\tfrac{1}{2}\theta_1)\sin(\tfrac{1}{2}\theta_2)\sin[\tfrac{1}{2}(\theta_1 - \theta_2)]\, d\theta_2\, d\theta_1$$

$$+ \frac{1}{\pi^2} \underset{\theta_2 - \theta_1 < 0}{\int_0^\pi \int_0^{2\pi}} \sin(\tfrac{1}{2}\theta_1)\sin(\tfrac{1}{2}\theta_2)\sin[\tfrac{1}{2}(\theta_1 - \theta_2)]\, d\theta_2\, d\theta_1$$

$$= \frac{1}{\pi^2} \int_0^\pi \sin(\tfrac{1}{2}\theta_1)\left[\int_{\theta_1}^{2\pi} \sin(\tfrac{1}{2}\theta_2)\sin[\tfrac{1}{2}(\theta_2 - \theta_1)]\, d\theta_2\right] d\theta_1$$

$$+\frac{1}{\pi^2}\int_0^{\pi}\sin(\tfrac{1}{2}\,\theta_1)$$

$$\times\left[\int_0^{\theta_1}\sin(\tfrac{1}{2}\,\theta_2)\,\sin[\tfrac{1}{2}(\theta_2-\theta_1)]\,d\theta_2\right]d\theta_1. \qquad (4)$$

But

$$\int(\tfrac{1}{2}\,\theta_2)\sin[\tfrac{1}{2}(\theta_2-\theta_1)]\,d\theta_2$$

$$=\int\sin(\tfrac{1}{2}\,\theta_2)[\sin(\tfrac{1}{2}\,\theta_2)\cos(\tfrac{1}{2}\,\theta_2)-\sin(\tfrac{1}{2}\,\theta_1)\cos(\tfrac{1}{2}\,\theta_2)]\,d\theta_2$$

$$=\cos(\tfrac{1}{2}\,\theta_1)\int\sin^2(\tfrac{1}{2}\,\theta_2)\,d\theta_2$$

$$-\sin(\tfrac{1}{2}\,\theta_1)\int\sin(\tfrac{1}{2}\,\theta_1)\cos(\tfrac{1}{2}\,\theta_2)\,d\theta_2$$

$$=\tfrac{1}{2}\cos(\tfrac{1}{2}\,\theta_1)\int(1-\cos\,\theta_2)\,d\theta_2$$

$$-\tfrac{1}{2}\sin(\tfrac{1}{2}\,\theta_2)\int\sin\,\theta_2\,d\theta_2 \qquad (5)$$

Write (4) as

$$\bar{A}=\frac{1}{\pi^2}\left[\int_0^{\pi}\sin(\tfrac{1}{2}\,\theta_1)I_1\,d\theta_1+\int_0^{\pi}\sin(\tfrac{1}{2}\,\theta_1)I_2\,d\theta_1\right], \qquad (6)$$

then

$$I_1\equiv\int_0^{2\pi}\sin(\tfrac{1}{2}\,\theta_2)\,\sin[\tfrac{1}{2}(\theta_2-\theta_1)]\,d\theta_2, \qquad (7)$$

and

$$I_2\equiv\int_0^{\theta_1}\sin(\tfrac{1}{2}\,\theta_2)\,\sin[\tfrac{1}{2}(\theta_1-\theta_2)]\,d\theta_2. \qquad (8)$$

From (6),

$$I_1=\tfrac{1}{2}\cos(\tfrac{1}{2}\,\theta_2)[\theta_2-\sin\,\theta_2]_{\theta_1}^{2\pi}+\tfrac{1}{2}\sin(\tfrac{1}{2}\,\theta_1)[\cos\,\theta_2]_{\theta_1}^{2\pi}$$

$$=\tfrac{1}{2}\cos(\tfrac{1}{2}\,\theta_1)(2\pi-\theta_1+\sin\,\theta_1)+\tfrac{1}{2}\sin(\tfrac{1}{2}\,\theta_1)(1-\cos\,\theta_1)$$

$$=\pi\cos(\tfrac{1}{2}\,\theta_1)-\tfrac{1}{2}\,\theta_1\cos(\tfrac{1}{2}\,\theta_1)$$

$$+\tfrac{1}{2}[\cos(\tfrac{1}{2}\,\theta_1)\sin\,\theta_1-\cos\,\theta_1\sin(\tfrac{1}{2}\,\theta_1)]+\tfrac{1}{2}\sin(\tfrac{1}{2}\,\theta_1)$$

$$=\pi\cos(\tfrac{1}{2}\,\theta_1)-\tfrac{1}{2}\,\theta_1\cos(\tfrac{1}{2}\,\theta_1)+\tfrac{1}{2}+\tfrac{1}{2}\sin(\theta_1-\tfrac{1}{2}\,\theta_1)$$

$$+\tfrac{1}{2}\sin(\tfrac{1}{2}\,\theta_1)$$

$$=\pi\cos(\tfrac{1}{2}\,\theta_1)-\tfrac{1}{2}\,\theta_1\cos(\tfrac{1}{2}\,\theta_1)+\sin(\tfrac{1}{2}\,\theta_1), \qquad (9)$$

so

$$\int_0^{\pi}I_1\sin(\tfrac{1}{2}\,\theta_1)\,d\theta_1=\tfrac{5}{4}\,\pi. \qquad (10)$$

Also,

$$I_2=\tfrac{1}{2}\cos(\tfrac{1}{2}\,\theta_1)[\sin\,\theta_2-\theta_2]_0^{\theta_1}-\tfrac{1}{2}\sin(\tfrac{1}{2}\,\theta_1)[\cos\,\theta]_0^{\theta_1}$$

$$=\tfrac{1}{2}\cos(\tfrac{1}{2}\,\theta_2)(\sin\,\theta_1-\theta_1)-\tfrac{1}{2}\sin(\tfrac{1}{2}\,\theta_1)(\cos\,\theta_1-1)$$

$$=-\tfrac{1}{2}\,\theta_1\cos(\tfrac{1}{2}\,\theta_1)+\tfrac{1}{2}[\sin\,\theta_1\cos(\tfrac{1}{2}\,\theta_1)$$

$$-\cos\,\theta_1\sin(\tfrac{1}{2}\,\theta_2)]+\tfrac{1}{2}\sin(\tfrac{1}{2}\,\theta_1)$$

$$=-\tfrac{1}{2}\,\theta_1\cos(\tfrac{1}{2}\,\theta_1)+\sin(\tfrac{1}{2}\,\theta_1), \qquad (11)$$

so

$$\int_0^{\pi}I_2\sin(\tfrac{1}{2}\,\theta_1)\,d\theta_1=\tfrac{1}{4}\,\pi. \qquad (12)$$

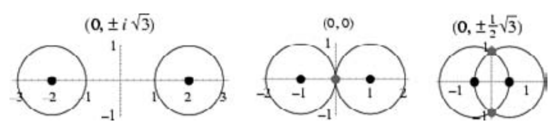
Combining (10) and (12) gives

$$\bar{A}=\frac{1}{\pi^2}\left(\frac{5\pi}{4}+\frac{\pi}{4}\right)=\frac{3}{2\pi}\approx 0.4775. \qquad (13)$$

The first few moments are

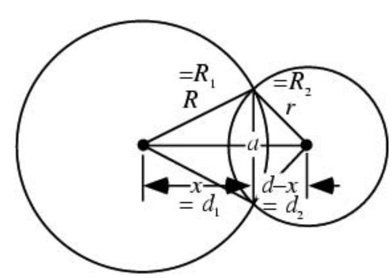
$$\mu_2'=\tfrac{3}{8} \qquad (14)$$

$$\mu_3'=\frac{41}{32\pi} \qquad (15)$$



$$\mu_4'=\tfrac{45}{128}, \qquad (16)$$

so the VARIANCE is



$$\sigma_A^2=\langle A\rangle^2-\langle A^2\rangle=\frac{3(\pi^2-6)}{8\pi^2}\approx 0.1470. \qquad (17)$$

See also CIRCLE LINE PICKING, DISK TRIANGLE PICKING, POINT-POINT DISTANCE–1-D, SPHERE POINT PICKING

Circle-Circle Intersection

Two circles may intersect in two imaginary points, a single degenerate point, or two distinct points.

Let two CIRCLES of RADII R and r and centered at (0, 0) and (d, 0) intersect in a LENS-shaped region.

The equations of the two circles are

$$x^2 + y^2 = R^2 \tag{1}$$

$$(x-d)^2 + y^2 = r^2. \tag{2}$$

Combining (1) and (2) gives

$$(x-d)^2 + (R^2 + x^2) = r^2. \tag{3}$$

Multiplying through and rearranging gives

$$x^2 - 2\,dx + d^2 - x^2 = r^2 - R^2. \tag{4}$$

Solving for x results in

$$x = \frac{d^2 - r^2 + R^2}{2d}. \tag{5}$$

The line connecting the cusps of the LENS therefore has half-length given by plugging x back in to obtain

$$y^2 = R^2 - x^2 = R^2 - \left(\frac{d^2 - r^2 + R^2}{2d}\right)^2$$

$$= \frac{4d^2R^2 - (d^2 - r^2 + R^2)^2}{4d^2}, \tag{6}$$

giving a half-height $y = a/2$ of

$$a = \frac{1}{d}\sqrt{4d^2R^2 - (d^2 - r^2 + R^2)^2}$$

$$= \frac{1}{d}[(-d + r - R)(-d - r + R)(-d + r + R)(d + r + R)]^{1/2}. \tag{7}$$

This same formulation applies directly to the SPHERE-SPHERE INTERSECTION problem.

To find the AREA of the asymmetric "LENS" in which the CIRCLES intersect, simply use the formula for the circular SEGMENT of radius R' and triangular height d'

$$A(R', d') = R'^2 \cos^{-1}\left(\frac{d'}{R'}\right) - d'\sqrt{R'^2 - d'^2} \tag{8}$$

twice, one for each half of the "LENS." Noting that the heights of the two segment triangles are

$$d_1 = x = \frac{d^2 - r^2 + R^2}{2d} \tag{9}$$

$$d_2 = d - x = \frac{d^2 + r^2 - R^2}{2d}. \tag{10}$$

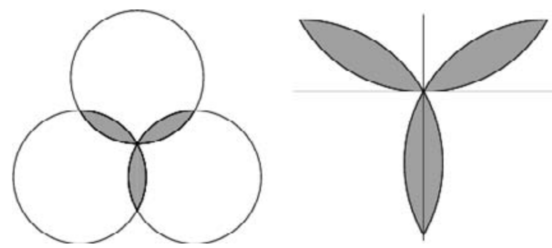
The result is

$$A = A(R, d_1) + A(r, d_2)$$

$$= r^2 \cos^{-1}\left(\frac{d^2 + r^2 - R^2}{2dr}\right) + R^2 \cos^{-1}\left(\frac{d^2 + R^2 - r^2}{2dR}\right)$$

$$-\tfrac{1}{2}\sqrt{(-d + r + R)(d + r - R)(d - r + R)(d + r + R)}. \tag{11}$$

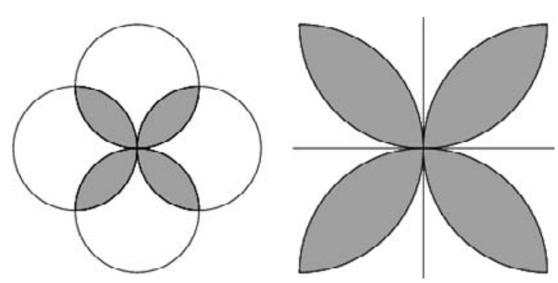
The limiting cases of this expression can be checked to give 0 when $d = R + r$ and



$$A = 2R^2 \cos^{-1}\left(\frac{d}{2R}\right) - \tfrac{1}{2}\,d\sqrt{4R^2 - d^2} \tag{12}$$

$$= 2A\left(\tfrac{1}{2}\,d,\ R\right) \tag{13}$$

when $r = R$, as expected. In order for half the area of two UNIT DISKS ($R = 1$) to overlap, set $A = \pi R^2/2 = \pi/2$ in the above equation

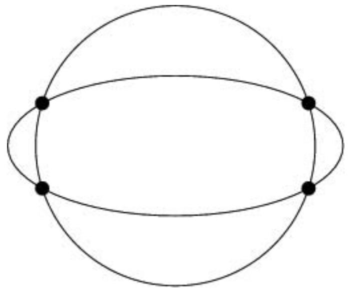


$$\tfrac{1}{2}\,\pi = 2\cos^{-1}\left(\tfrac{1}{2}\,d\right) - \tfrac{1}{2}\,d\sqrt{4 - d^2} \tag{14}$$

and solve numerically, yielding $d \approx 0.807946$.

If three symmetrically placed equal circles intersect in a single point, as illustrated above, the total area of the three lens-shaped regions formed by the pairwise intersection of circles is given by

$$A = \pi - \tfrac{3}{2}\sqrt{3}. \tag{15}$$



Similarly, the total area of the four lens-shaped regions formed by the pairwise intersection of circles is given by

$$A = 2(\pi - 2). \tag{16}$$

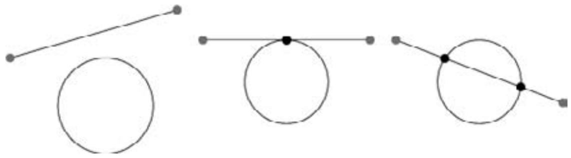
See also BORROMEAN RINGS, BROCARD TRIANGLES, CIRCLE-ELLIPSE INTERSECTION, CIRCLE-LINE INTERSECTION, CIRCULAR TRIANGLE, DOUBLE BUBBLE, GOAT PROBLEM, LENS, REULEAUX TRIANGLE, SEGMENT, SPHERE-SPHERE INTERSECTION, TRIQUETRA, VENN DIAGRAM

Circle-Ellipse Intersection

An ellipse intersects a circle in 0, 1, 2, 3, or 4 points. The points of intersection of a circle of center $(x_0,\ y_0)$ and radius r with an ellipse of semi-major and semi-minor axes a and b, respectively and center $(x_e,\ y_e)$ can be determined by simultaneously solving

$$(x-x_0)^2+(y-y_0)^2=r^2 \quad (1)$$

$$\frac{(x-x_e)^2}{a^2}+\frac{(y-y_e)^2}{b^2}=1. \quad (2)$$



If $(x_0,\ y_0)=(x_e,\ y_e)=(0,\ 0)$, then the solution takes on the particularly simple form

$$x=\pm a\sqrt{\frac{r^2-b^2}{a^2-b^2}} \quad (3)$$

$$y=\pm b\sqrt{\frac{a^2-r^2}{a^2-b^2}}. \quad (4)$$

See also CIRCLE, CIRCLE-CIRCLE INTERSECTION, ELLIPSE

Circle-Line Intersection

A LINE determined by two points $(x_1,\ y_1)$ and $(x_2,\ y_2)$ may intersect a CIRCLE of RADIUS r and center (0, 0) in two imaginary points, a degenerate single point (corresponding to the line being tangent to the circle), or two real points. Defining

$$d_x=x_2-x_1 \quad (1)$$

$$d_y=y_2-y_1 \quad (2)$$

$$d_r=\sqrt{d_x^2+d_y^2} \quad (3)$$

$$D=\begin{vmatrix} x_1 & x_2 \\ y_1 & y_2 \end{vmatrix}=x_1y_2-x_2y_1 \quad (4)$$

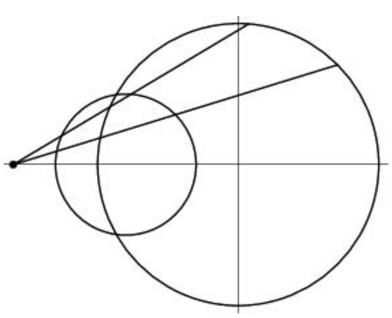
gives the points of intersection as

$$x=\frac{-Dd_y\pm \operatorname{sgn}^*(d_y)\,d_x\sqrt{r^2d_r^2-D^2}}{d_r^2}, \quad (5)$$

$$y=\frac{-Dd_x\pm |d_y|\sqrt{r^2d_r^2-D^2}}{d_r^2}, \quad (6)$$

where the function sgn* is defined as

$$\operatorname{sgn}^*(x)\equiv\begin{cases}-1 & \text{for } x<0\\ 1 & \text{otherwise.}\end{cases} \quad (7)$$



The discriminant

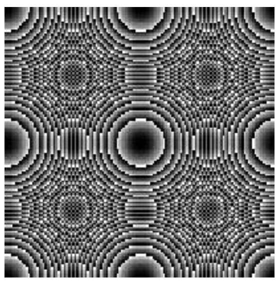
$$\Delta\equiv r^2d_r^2-D^2 \quad (8)$$

therefore determines the incidence of the line and circle as summarized in the following table.

Δ	Incidence
$\Delta<0$	no intersection
$\Delta=0$	tangent
$\Delta>0$	intersection

Circle-Point Midpoint Theorem

Taking the locus of MIDPOINTS from a fixed point to a circle of radius r results in a circle of radius $r/2$. This



follows trivially from

$$\mathbf{r}(\theta) = \begin{bmatrix} -x \\ 0 \end{bmatrix} + \frac{1}{2}\left(\begin{bmatrix} r\cos\theta \\ r\sin\theta \end{bmatrix} - \begin{bmatrix} -x \\ 0 \end{bmatrix}\right) = \begin{bmatrix} \frac{1}{2}r\cos\theta - \frac{1}{2}x \\ \frac{1}{2}\sin\theta \end{bmatrix}.$$

Circuit

GRAPH CYCLE

Circuit Rank

Also known as the CYCLOMATIC NUMBER. The circuit rank is the smallest number of EDGES γ which must be removed from a GRAPH of N EDGES and n nodes such that no CIRCUIT remains.

$$\gamma = N - n + 1.$$

Circulant Determinant

Gradshteyn and Ryzhik (2000) define circulants by

$$\begin{vmatrix} x_1 & x_2 & x_3 & \cdots & x_n \\ x_n & x_1 & x_2 & \cdots & x_{n-1} \\ x_{n-1} & x_n & x_1 & \cdots & x_{n-2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ x_2 & x_3 & x_4 & \cdots & x_1 \end{vmatrix} = \prod_{j=1} (x_1 + x_2\omega_j + x_3\omega_j^2 + \ldots + x_n\omega_j^{n-1}) \qquad (1)$$

where ω_j is the nth ROOT OF UNITY. The second-order circulant determinant is

$$\begin{vmatrix} x_1 & x_2 \\ x_2 & x_1 \end{vmatrix} = (x_1 + x_2)(x_1 - x_2), \qquad (2)$$

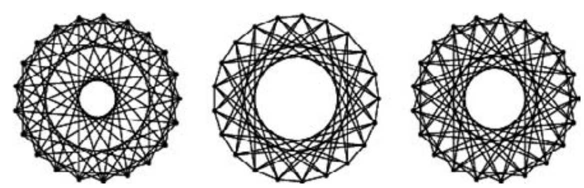
and the third order is

$$\begin{vmatrix} x_1 & x_2 & x_3 \\ x_3 & x_1 & x_2 \\ x_2 & x_3 & x_1 \end{vmatrix} = (x_1 + x_2 + x_3)(x_1 + \omega x_2 + \omega^2 x_3) \times (x_1 + \omega^2 x_2 + \omega x_3), \qquad (3)$$

where ω and ω^2 are the COMPLEX CUBE ROOTS of UNITY.

The EIGENVALUES λ of the corresponding $n \times n$ CIRCULANT MATRIX are

$$\lambda_j = x_1 + x_2\omega_j + x_3\omega_j^2 + \ldots + x_n\omega_j^{n-1}. \qquad (4)$$



See also CIRCULANT MATRIX

Circulant Graph

A GRAPH of n VERTICES in which the ith VERTEX is adjacent to the $(i+j)$th and $(i-j)$th VERTICES for each j in a list l. The circulant graph $Ci_{1,2,\ldots,\lfloor n/2 \rfloor}(n)$ gives the COMPLETE GRAPH K_n and the graph $Ci_1(n)$ gives the CYCLIC GRAPH C_n.

The number of circulant graphs on $n = 1, 2, \ldots$ nodes (counting empty graphs) are given by 1, 2, 2, 4, 3, 8, 4, 12, ... (Sloane's A049287). Note that these numbers

cannot be counted simply by enumerating the number of nonempty subsets of $\{1, 2, \ldots, \lfloor n/2 \rfloor\}$ since, for example, $Ci_1(5) = Ci_2(5) = C_5$. There is an easy formula for prime orders, and formulas are known for squarefree and prime-squared orders.

Special cases are summarized in the table below.

Graph	Symbol
OCTAHEDRAL GRAPH	$Ci_{1,\,2}(6)$
16-CELL	$Ci_{1,\,2,\,3}(8)$

See also 16-CELL, OCTAHEDRAL GRAPH

Circulant Matrix

An $n \times n$ MATRIX C defined as follows,

$$\mathsf{C}_n = \begin{bmatrix} 1 & \binom{n}{1} & \binom{n}{2} & \cdots & \binom{n}{n-1} \\ \binom{n}{n-1} & 1 & \binom{n}{1} & \cdots & \binom{n}{n-2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \binom{n}{1} & \binom{n}{2} & \binom{n}{3} & \cdots & 1 \end{bmatrix},$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT. The DETERMINANT of C_n is given by the beautiful formula

$$\mathsf{C}_n = \prod_{j=0}^{n-1} [(1+\omega_j)^n - 1],$$

where $\omega_0 \equiv 1$, ω_1, ..., ω_{n-1} are the nth ROOTS OF UNITY. The determinants for $n = 1, 2, \ldots$, are given by 1, -3, 28, -375, 3751, 0, 6835648, -1343091375, 364668913756, ... (Sloane's A048954), which is 0 when $n \equiv 0 \pmod 6$.

Circulant matrices are examples of LATIN SQUARES.

Circular Cylinder

CYLINDER

Circular Cylindrical Coordinates

CYLINDRICAL COORDINATES

Circular Functions

The functions describing the horizontal and vertical positions of a point on a CIRCLE as a function of ANGLE (COSINE and SINE) and those functions derived from them:

$$\cot x \equiv \frac{1}{\tan x} = \frac{\cos x}{\sin x} \tag{1}$$

$$\csc x \equiv \frac{1}{\sin x} \tag{2}$$

$$\sec x \equiv \frac{1}{\cos x} \tag{3}$$

$$\tan x \equiv \frac{\sin x}{\cos x}. \tag{4}$$

Circular functions are also called TRIGONOMETRIC FUNCTIONS, and the study of circular functions is called TRIGONOMETRY.

See also COSECANT, COSINE, COTANGENT, ELLIPTIC FUNCTION, GENERALIZED HYPERBOLIC FUNCTIONS, HYPERBOLIC FUNCTIONS, SECANT, SINE, TANGENT, TRIGONOMETRIC FUNCTIONS, TRIGONOMETRY

References

Circular Permutation

The number of ways to arrange n distinct objects along a FIXED (i.e., cannot be picked up out of the plane and turned over) CIRCLE is

$$P_n = (n-1)!.$$

The number is $(n-1)!$ instead of the usual FACTORIAL $n!$ since all CYCLIC PERMUTATIONS of objects are equivalent because the CIRCLE can be rotated.

For example, of the $3! = 6$ permutations of three objects, the $(3-1)! = 2$ distinct circular permutations are {1, 2, 3} and {1, 3, 2}. Similarly, of the $4! = 24$ permutations of four objects, the $(3-1)! = 6$ distinct circular permutations are {1, 2, 3, 4}, {1, 2, 4, 3}, {1, 3, 2, 4}, {1, 3, 4, 2}, {1, 4, 2, 3}, and {1, 4, 3, 2}. Of these, there are only three FREE permutations (i.e., inequivalent when flipping the circle is allowed): {1, 2, 3, 4}, {1, 2, 4, 3}, and {1, 3, 2, 4}. The number of free circular permutations of order n is $P'_n = 1$ for $n = 1$, 2, and

$$P'_n = \tfrac{1}{2}(n-1)!$$

for $n \geq 3$, giving the sequence 1, 1, 1, 3, 12, 60, 360, 2520, ... (Sloane's A001710).

Circular Reciprocation

RECIPROCATION

Circular Triangle

A triangle ABC formed by three circular ARCS. By extending the arcs into complete circles, the points of intersection A', B', and C' are obtained. This gives the three circular triangles, $A'B'C'$, $AB'C'$, $A'BC'$, and $A'B'C$, which are called the ASSOCIATED TRIANGLES to ABC. In addition, circular triangles $A'B'C'$, $AB'C'$, $A'BC'$, and $A'B'C$ can also be drawn.

The circular triangle and its associated circles have a total of eight INCIRCLES and six CIRCUMCIRCLE. These systems of circles have some remarkable properties, including the HART CIRCLE, which is an analog of the NINE-POINT CIRCLE in FEUERBACH'S THEOREM.

See also APOLLONIUS' PROBLEM, ARC, ASSOCIATED TRIANGLES, CIRCLE-CIRCLE INTERSECTION, FEUERBACH'S THEOREM, HART CIRCLE, HARUKI'S THEOREM, NINE-POINT CIRCLE, SPHERICAL TRIANGLE, TRIQUETRA

Circular-Cylinder Coordinates

CYLINDRICAL COORDINATES

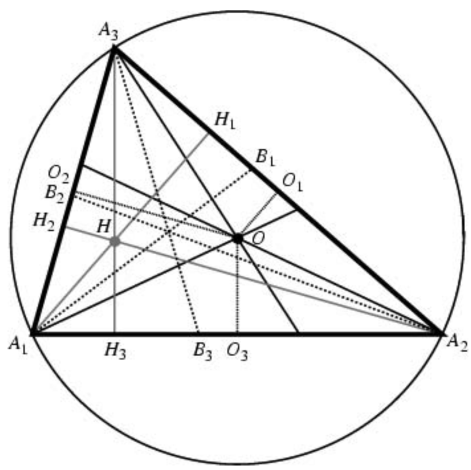
Circumcenter

The center O of a TRIANGLE'S CIRCUMCIRCLE. It can be found as the intersection of the PERPENDICULAR BISECTORS. If the TRIANGLE is ACUTE, the circumcenter is in the interior of the TRIANGLE. In a RIGHT TRIANGLE, the circumcenter is the MIDPOINT of the HYPOTENUSE.

$$\overline{OO_1} + \overline{OO_2} + \overline{OO_3} = R + r, \quad (1)$$

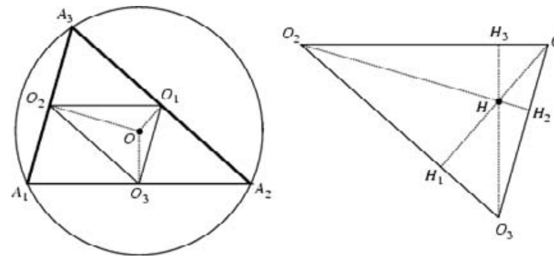
where O_i are the MIDPOINTS of sides A_i, R is the CIRCUMRADIUS, and r is the INRADIUS (Johnson 1929, p. 190). The TRILINEAR COORDINATES of the circumcenter are

$$\cos A : \cos B : \cos C, \quad (2)$$



and the exact trilinears are therefore

$$R \cos A : R \cos B : R \cos C. \quad (3)$$



The AREAL COORDINATES are

$$(\tfrac{1}{2} a \cot A,\ \tfrac{1}{2} b \cot B,\ \tfrac{1}{2} c \cot C). \quad (4)$$

The distance between the INCENTER and circumcenter is $\sqrt{R(R-2r)}$. Given an interior point, the distances to the VERTICES are equal IFF this point is the circumcenter. It lies on the BROCARD AXIS.

The circumcenter O and ORTHOCENTER H are ISOGONAL CONJUGATES.

The ORTHOCENTER H of the PEDAL TRIANGLE $\Delta O_1O_2O_3$ formed by the CIRCUMCENTER O concurs with the circumcenter O itself, as illustrated above. The circumcenter also lies on the EULER LINE.

See also BROCARD DIAMETER, CARNOT'S THEOREM, CENTROID (TRIANGLE), CIRCLE, EULER LINE, INCENTER, LESTER CIRCLE, ORTHOCENTER

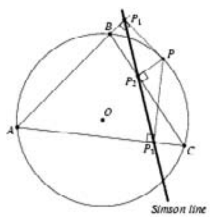
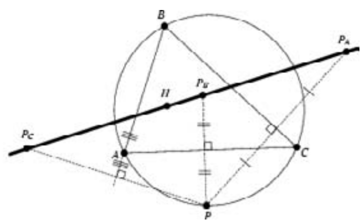
Circumcircle





A TRIANGLE'S circumscribed circle. Its center O is called the CIRCUMCENTER, and its RADIUS R the CIRCUMRADIUS. The circumcircle can be specified using TRILINEAR COORDINATES as

$$\beta\gamma a + \gamma\alpha b + \alpha\beta c = 0. \quad (1)$$

The STEINER POINT S and TARRY POINT T lie on the

circumcircle.

When an arbitrary point P is taken on the circumcircle, then the feet P_1, P_2, and P_3 of the perpendiculars from P to the sides (or their extensions) of the TRIANGLE are COLLINEAR on a line called the SIMSON LINE. Furthermore, the reflections P_A, P_B, P_C of any point P on the CIRCUMCIRCLE taken with respect to the sides BC, AC, AB of the triangle are COLLINEAR, not only with each other but also with the ORTHOCENTER H (Honsberger 1995, pp. 44–7).

The tangent to a triangle's circumcircle at a vertex is ANTIPARALLEL to the opposite side, the sides of the ORTHIC TRIANGLE are parallel to the tangents to the circumcircle at the vertices, and the radius of the circumcircle at a vertex is perpendicular to all lines ANTIPARALLEL to the opposite sides (Johnson 1929, pp. 172–73).

A GEOMETRIC CONSTRUCTION for the circumcircle is given by Pedoe (1995, pp. xii-xiii). The equation for the circumcircle of the TRIANGLE with VERTICES (x_i, y_i) for $i = 1, 2, 3$ is

$$\begin{vmatrix} x^2+y^2 & x & y & 1 \\ x_1^2+y_1^2 & x_1 & y_1 & 1 \\ x_2^2+y_2^2 & x_2 & y_2 & 1 \\ x_3^2+y_3^2 & x_3 & y_3 & 1 \end{vmatrix} = 0. \tag{2}$$

Expanding the DETERMINANT,

$$a(x^2+y^2)+2dx+2fy+g=0, \tag{3}$$

where

$$a = \begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{vmatrix} \tag{4}$$

$$d = -\tfrac{1}{2}\begin{vmatrix} x_1^2+y_1^2 & y_1 & 1 \\ x_2^2+y_2^2 & y_2 & 1 \\ x_3^2+y_3^2 & y_3 & 1 \end{vmatrix} \tag{5}$$

$$f = \tfrac{1}{2}\begin{vmatrix} x_1^2+y_1^2 & x_1 & 1 \\ x_2^2+y_2^2 & x_2 & 1 \\ x_3^2+y_3^2 & x_3 & 1 \end{vmatrix} \tag{6}$$

$$g = -\begin{vmatrix} x_1^2+y_1^2 & x_1 & y_1 \\ x_2^2+y_2^2 & x_2 & y_2 \\ x_3^2+y_3^2 & x_3 & y_3 \end{vmatrix}. \tag{7}$$

COMPLETING THE SQUARE gives

$$a\left(x+\frac{d}{a}\right)^2+a\left(y+\frac{f}{a}\right)^2-\frac{d^2}{a}-\frac{f^2}{a}+g=0 \tag{8}$$

which is a CIRCLE OF THE FORM

$$(x-x_0)^2+(y-y_0)^2=r^2, \tag{9}$$

with CIRCUMCENTER

$$x_0 = -\frac{d}{a} \tag{10}$$

$$y_0 = -\frac{f}{a} \tag{11}$$

and CIRCUMRADIUS

$$r = \sqrt{\frac{f^2+d^2}{a^2}-\frac{g}{a}}. \tag{12}$$

If a polygon with side lengths a, b, c, ... and standard trilinear equations $\alpha = 0$, $\beta = 0$, $\gamma = 0$, ... has a circumcircle, then for any point of the circle,

$$\frac{a}{\alpha}+\frac{b}{\beta}+\frac{c}{\gamma}+\ldots=0 \tag{13}$$

(Casey 1878, 1893).

Circumference

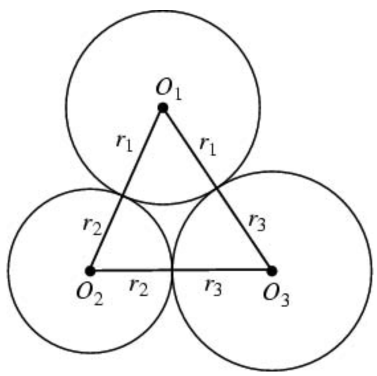
The PERIMETER of a CIRCLE. For RADIUS r or DIAMETER $d = 2r$,

$$C = 2\pi r = \pi d,$$

where π is PI.

See also CIRCLE, DIAMETER, GRAPH CIRCUMFERENCE, PERIMETER, PI, RADIUS

Circumflex

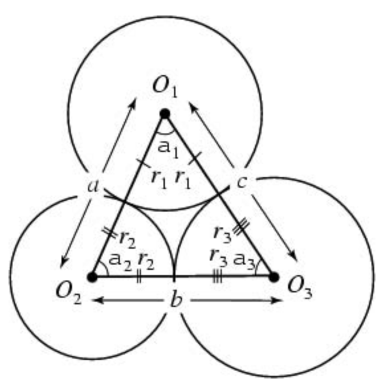


Hat

Circuminscribed

Given two closed curves, the circuminscribed curve is simultaneously inscribed in the outer one and circumscribed on the inner one.

See also Poncelet's Porism, Steiner Chain



Circumradius

The radius of a triangle's circumcircle or of a polyhedron's circumsphere, denoted R. For a triangle,

$$R = \frac{abc}{\sqrt{(a+b+c)(b+c-a)(c+a-b)(a+b-c)}} \quad (1)$$

where the side lengths of the triangle are a, b, and c.

This equation can also be expressed in terms of the radii of the three mutually tangent circles centered at the triangle's vertices. Relabeling the diagram for the Soddy circles with vertices O_1, O_2, and O_3 and the radii r_1, r_2, and r_3, and using

$$a = r_1 + r_2 \quad (2)$$

$$b = r_2 + r_3 \quad (3)$$

$$c = r_1 + r_3 \quad (4)$$

then gives

$$R = \frac{(r_1+r_2)(r_1+r_3)(r_2+r_3)}{4\sqrt{r_1 r_2 r_3 (r_1+r_2+r_3)}}. \quad (5)$$

If O is the circumcenter and M is the triangle centroid, then

$$\overline{OM}^2 = R^2 - \tfrac{1}{9}(a^2+b^2+c^2). \quad (6)$$

$$Rr = \frac{abc}{4s} \quad (7)$$

$$\cos\alpha_1 + \cos\alpha_2 + \cos\alpha_3 = 1 + \frac{r}{R} \quad (8)$$

$$r = 2R\cos\alpha_1\cos\alpha_2\cos\alpha_3 \quad (9)$$

(Johnson 1929, pp. 189–91). Let d be the distance between inradius r and circumradius R, $d = \overline{rR}$. Then

$$R^2 - d^2 = 2Rr \quad (10)$$

$$\frac{1}{R-d} + \frac{1}{R+d} = \frac{1}{r} \quad (11)$$

(Mackay 1886–7; Casey 1888, pp. 74–5). These and many other identities are given in Johnson (1929, pp. 186–90).

The hypotenuse of a right triangle is a diameter of the triangle's circumcircle, so the circumradius is given by

$$R = \tfrac{1}{2}c, \quad (12)$$

where c is the hypotenuse.

For an Archimedean solid, expressing the circumradius in terms of the inradius r and midradius ρ gives

$$R = \tfrac{1}{2}(r + \sqrt{r^2 + a^2}) \quad (13)$$

$$= \sqrt{\rho^2 + \tfrac{1}{4}a^2} \quad (14)$$

for an Archimedean solid.

Cissoid of Diocles

A curve invented by Diocles in about 180 BC in connection with his attempt to duplicate the cube by geometrical methods. The name "cissoid" first appears in the work of Geminus about 100 years later. Fermat and Roberval constructed the tangent in 1634. Huygens and Wallis found, in 1658, that the AREA between the curve and its asymptote was $3a$ (MacTutor Archive). From a given point there are either one or three TANGENTS to the cissoid.
Given an origin O and a point P on the curve, let S be the point where the extension of the line OP intersects the line $x = 2a$ and R be the intersection of the CIRCLE of RADIUS a and center $(a, 0)$ with the extension of OP. Then the cissoid of Diocles is the curve which satisfies $OP = RS$.

The cissoid of Diocles is the ROULETTE of the VERTEX of a PARABOLA rolling on an equal PARABOLA. Newton gave a method of drawing the cissoid of Diocles using two line segments of equal length at RIGHT ANGLES. If they are moved so that one line always passes through a fixed point and the end of the other line segment slides along a straight line, then the MIDPOINT of the sliding line segment traces out a cissoid of Diocles.

The cissoid of Diocles is given by the PARAMETRIC EQUATIONS

$$x = 2a \sin^2 \theta \qquad (1)$$

$$y = \frac{2a \sin^3 \theta}{\cos \theta}. \qquad (2)$$

Converting these to POLAR COORDINATES gives

$$r^2 = x^2 + y^2 = 4a^2 \left(\sin^4 \theta + \frac{\sin^6 \theta}{\cos^2 \theta} \right)$$

$$= 4a^2 \sin^4 \theta (1 + \tan^2 \theta) = 4a^2 \sin^4 \theta \sec^2 \theta, \quad (3)$$

so

$$r = 2a \sin^2 \theta \sec \theta = 2a \sin \theta \tan \theta. \quad (4)$$

In CARTESIAN COORDINATES,

$$\frac{x^3}{2a - x} = \frac{8a^3 \sin^6 \theta}{2a - 2a \sin^2 \theta} = 4a^2 \frac{\sin^6 \theta}{1 - \sin^2 \theta}$$

$$= 4a^2 \frac{\sin^6 \theta}{\cos^2 \theta} = y^2. \quad (5)$$

An equivalent form is

$$x(x^2 + y^2) = 2ay^2. \quad (6)$$

Using the alternative parametric form

$$x(t) = \frac{2at^2}{1 + t^2} \quad (7)$$

$$y(t) = \frac{2at^3}{1 + t^2} \quad (8)$$

(Gray 1997), gives the CURVATURE as

$$\kappa(t) = \frac{3}{a|t|(t^2 + 4)^{3/2}}. \quad (9)$$

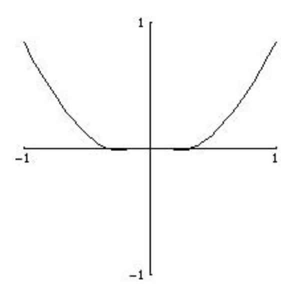
Cissoid of Diocles Caustic

The CAUSTIC of the cissoid where the RADIANT POINT is taken as $(8a, 0)$ is a CARDIOID.

Cissoid of Diocles Inverse Curve

If the cusp of the CISSOID OF DIOCLES is taken as the INVERSION CENTER, then the cissoid inverts to a PARABOLA.

Cissoid of Diocles Pedal Curve



The PEDAL CURVE of the cissoid, when the PEDAL POINT is on the axis beyond the ASYMPTOTE at a distance from the cusp which is four times that of the ASYMPTOTE is a CARDIOID.

C-k Function

A function with k CONTINUOUS DERIVATIVES is called a C^k function. In order to specify a C^k function on a domain X, the notation $C^k(X)$ is used. The most common C^k space is C^0, the space of CONTINUOUS FUNCTIONS, whereas C^1 is the space of CONTINUOUSLY DIFFERENTIABLE FUNCTIONS. Cartan (1977, p. 327) writes humorously that "by 'differentiable,' we mean of class C^k, with k being as large as necessary."

Of course, any SMOOTH FUNCTION is C^k, and when $l > k$, then any C^l function is C^k. It is natural to think of a C^k function as being a little bit rough, but the graph of a C^3 function "looks" smooth.

Examples of C^k functions are $|x|^{k+1}$ (for k even) and $x^{k+1} \sin(1/x)$, which do not have a $(k+1)$st derivative at 0.

The notion of C^k function may be restricted to those whose first k derivatives are BOUNDED functions. The reason for this restriction is that the set of C^k functions has a NORM which makes it a BANACH SPACE,

$$\|f\|_{C^k(X)} = \sum_{n=0}^{k} \sup_{x \in X} |f^{(n)}(x)|.$$

Clairaut's Difference Equation

This entry contributed by RONALD M. AARTS

Clairaut's difference equation is a special case of Lagrange's equation (Sokolnikoff and Redheffer 1958) defined by

$$u_k = k\Delta u_k + F(\Delta u_k),$$

or in "x notation,"

$$y = x\,\frac{\Delta y}{\Delta x} + F\left(\frac{\Delta y}{\Delta x}\right)$$

(Spiegel 1970). It is so named by analogy with CLAIRAUT'S DIFFERENTIAL EQUATION

$$y = x\,\frac{dy}{dx} + F\left(\frac{dy}{dx}\right).$$

See also CLAIRAUT'S DIFFERENTIAL EQUATION

References

Sokolnikoff, I. S. and Redheffer, R. M. *Mathematics of Physics and Modern Engineering.* New York: McGraw-Hill, 1958.

Clairaut's Differential Equation

$$y = x\,\frac{dy}{dx} + f\left(\frac{dy}{dx}\right) \tag{1}$$

or

$$y = px + f(p), \tag{2}$$

where f is a FUNCTION of one variable and $p \equiv dy/dx$. The general solution is

$$y = cx + f(c). \tag{3}$$

The singular solution ENVELOPES are $x = -f'(c)$ and $y = f(c) - cf'(c)$.

A PARTIAL DIFFERENTIAL EQUATION known as Clairaut's equation is given by

$$u = xu_x + yu_y + f(u_x,\ u_y) \tag{4}$$

(Iyanaga and Kawada 1980, p. 1446; Zwillinger 1997, p. 132).

Clarity

The RATIO of a measure of the size of a "fit" to the size of a "residual."

References

Tukey, J. W. *Explanatory Data Analysis.* Reading, MA: Addison-Wesley, p. 667, 1977.

Clark's Triangle

A NUMBER TRIANGLE created by setting the vertex equal to 0, filling one diagonal with 1s, the other diagonal with multiples of an INTEGER f, and filling in the remaining entries by summing the elements on either side from one row above. Call the first column $n = 0$ and the last column $m = n$ so that

$$c(m,\ 0) = fm \tag{1}$$

$$c(m,\ m) = 1 \tag{2}$$

then use the RECURRENCE RELATION

$$c(m,\ n) = c(m-1,\ n-1) + c(m-1,\ n) \tag{3}$$

to compute the rest of the entries. For $n = 1$, we have

$$c(m,\ 1) = c(m-1,\ 0) + c(m-1,\ 1) \tag{4}$$

$$c(m,\ 1) - c(m-1,\ 1) = c(m-1,\ 0) = f(m-1). \tag{5}$$

For arbitrary m, the value can be computed by

SUMMING this RECURRENCE,

$$c(m,\ 1)=f\left(\sum_{k=1}^{m-1} k\right)+1=\tfrac{1}{2}fm(m-1)+1. \tag{6}$$

Now, for $n=2$ we have

$$c(m,\ 2)=c(m-1,\ 1)+c(m-1,\ 2) \tag{7}$$

$$c(m,\ 2)-c(m-1,\ 2)=c(m-1,\ 1)$$
$$=\tfrac{1}{2}f(m-1)m+1, \tag{8}$$

so SUMMING the RECURRENCE gives

$$c(m,\ 2)=\sum_{k=1}^{m-1}[\tfrac{1}{2}fk(k-1)+1]=\sum_{k=1}^{m}(\tfrac{1}{2}fk^2-\tfrac{1}{2}fk+1)$$
$$=\tfrac{1}{2}f[\tfrac{1}{6}m(m+1)(2m+1)]-\tfrac{1}{2}f[\tfrac{1}{2}m(m+1)]+m$$
$$=\tfrac{1}{6}(m-1)(fm^2-2fm+6). \tag{9}$$

Similarly, for $n=3$ we have

$$c(m,\ 3)-c(m-1,\ 3)=c(m-1,\ 2)$$
$$=\tfrac{1}{6}fm^3-fm^2+(\tfrac{11}{6}f+1)m-(f+2). \tag{10}$$

Taking the SUM,

$$c(m,\ 3)=\sum_{k=2}^{m}\tfrac{1}{6}fk^3-fk^2+(\tfrac{11}{6}f+1)k-(f+2). \tag{11}$$

Evaluating the SUM gives

$$c(m,\ 3)=\tfrac{1}{24}(m-1)(m-2)(fm^2-3fm+12). \tag{12}$$

So far, this has just been relatively boring ALGEBRA. But the amazing part is that if $f=6$ is chosen as the INTEGER, then $c(m,\ 2)$ and $c(m,\ 3)$ simplify to

$$c(m,\ 2)=\tfrac{1}{6}(m-1)(6m^2-12m+6)=(m-1)^3 \tag{13}$$

$$c(m,\ 3)=\tfrac{1}{4}(m-1)^2(m-2)^2, \tag{14}$$

which are consecutive CUBES $(m-1)^3$ and nonconsecutive SQUARES $n^2=[(m-1)(m-2)/2]^2$.

Class

The word "class" has many specialized meanings in mathematics in which it refers to a group of objects with some common property (e.g., CHARACTERISTIC CLASS or CONJUGACY CLASS.)

In statistics, a class is a grouping of values by which data is binned for computation of a FREQUENCY DISTRIBUTION (Kenney and Keeping 1962, p. 14). The range of values of a given class is called a CLASS INTERVAL, the boundaries of an interval are called CLASS LIMITS, and the middle of a CLASS INTERVAL is called the CLASS MARK.

class interval	class mark	absolute frequency	relative frequency	cumulative absolute frequency	relative cumulative frequency
0.00–9.99	5	1	0.01	1	0.01
10.00–9.99	15	3	0.03	4	0.04
20.00–9.99	25	8	0.08	12	0.12
30.00–9.99	35	18	0.18	30	0.30
40.00–9.99	45	24	0.24	54	0.54

Class (Group)

CONJUGACY CLASS

Class (Map)

A MAP $u: \mathbb{R}^n \to \mathbb{R}^n$ from a DOMAIN G is called a map of class C^r if each component of

$$u(x) = (u_1(x_1, \ldots, x_n), \ldots, u_m(x_1, \ldots, x_n))$$

is of class C^r ($0 \leq r \leq \infty$ or $r = \omega$) in G, where C^d denotes a continuous function which is differentiable d times.

Class (Multiply Perfect Number)

The number k in the expression $s(n) = kn$ for a MULTIPLY PERFECT NUMBER is called its class.

See also MULTIPLY PERFECT NUMBER

Class (Set)

A class is a generalized set invented to get around RUSSELL'S PARADOX while retaining the arbitrary criteria for membership which leads to difficulty for SETS. The members of classes are SETS, but it is possible to have the class C of "all SETS which are not members of themselves" without producing a PARADOX (since C is a PROPER CLASS (and not a SET), it is not a candidate for membership in C).

The distinction between classes and sets is a concept from VON NEUMANN-BERNAYS-GÖDEL SET THEORY.

Class Boundaries

Because of rounding, the stated CLASS LIMITS do not correspond to the actual ranges of data falling in them. For example, if the CLASS LIMITS are 1.00 and 2.00, then all values between 0.95 and 2.05 would actually fall in the given CLASS, so the class boundaries are 0.95 and 2.05 (Kenney and Keeping 1962, p. 17).

Class Interval

One of the ranges into which data in a FREQUENCY DISTRIBUTION table (or HISTOGRAM) are BINNED. The ends of a class interval are called CLASS LIMITS, and the middle of an interval is called a CLASS MARK.

Class Number

For any IDEAL I, there is an IDEAL I_i such that

$$II_i = z, \tag{1}$$

where z is a PRINCIPAL IDEAL, (i.e., an IDEAL of rank 1). Moreover, there is a finite list of ideals I_i such that

this equation may be satisfied for every I. The size of this list is known as the class number. When the class number is 1, the RING corresponding to a given IDEAL has unique factorization and, in a sense, the class number is a measure of the failure of unique factorization in the original number ring.

A finite series giving exactly the class number of a RING is known as a CLASS NUMBER FORMULA. A CLASS NUMBER FORMULA is known for the full ring of cyclotomic integers, as well as for any subring of the cyclotomic integers. Finding the class number is a computationally difficult problem.

Let $h(d)$ denote the class number of a quadratic ring, corresponding to the BINARY QUADRATIC FORM

$$ax^2 + bxy + cy^2, \tag{2}$$

with DISCRIMINANT

$$d \equiv b^2 - 4ac. \tag{3}$$

Then the class number $h(d)$ for DISCRIMINANT d gives the number of possible factorizations of $ax^2 + bxy + cy^2$ in the QUADRATIC FIELD $\mathbb{Q}(\sqrt{d})$. Here, the factors are of the form $x + y\sqrt{d}$, with x and y half INTEGERS.

Some fairly sophisticated mathematics shows that the class number for discriminant d can be given by the CLASS NUMBER FORMULA

$$h(d) \equiv \begin{cases} -\dfrac{1}{2\ln \eta(d)} \displaystyle\sum_{r=1}^{d-1} (d/r) \ln \sin\left(\frac{\pi r}{d}\right) & \text{for } d > 0 \\ -\dfrac{w(d)}{2|d|} \displaystyle\sum_{r=1}^{|d|-1} (d/r) r & \text{for } d < 0, \end{cases} \tag{4}$$

where (d/r) is the KRONECKER SYMBOL, $\eta(d)$ is the FUNDAMENTAL UNIT, $w(d)$ is the number of substitutions which leave the BINARY QUADRATIC FORM unchanged

$$w(d) = \begin{cases} 6 & \text{for } d = -3 \\ 4 & \text{for } d = -4 \\ 2 & \text{otherwise,} \end{cases} \tag{5}$$

and the sums are taken over all terms where the KRONECKER SYMBOL is defined (Cohn 1980). The class number for $d > 0$ can also be written

$$\eta^{2h(d)} = \prod_{r=1}^{d-1} \sin^{-(d/r)}\left(\frac{\pi r}{d}\right) \tag{6}$$

for $d > 0$, where the PRODUCT is taken over terms for which the KRONECKER SYMBOL is defined.

The class number $h(d)$ is related to the DIRICHLET L-SERIES by

$$h(d) = \frac{L_d(1)}{\kappa(d)}, \tag{7}$$

where $\kappa(d)$ is the DIRICHLET STRUCTURE CONSTANT.

Oesterlé (1985) showed that class number $h(-d)$ satisfies the INEQUALITY

$$h(-d) > \frac{1}{7000} \prod_{p|d}{}^{*} \left(1 - \frac{\lfloor 2\sqrt{p} \rfloor}{p+1}\right) \ln d, \tag{8}$$

for $-d < 0$, where $\lfloor x \rfloor$ is the FLOOR FUNCTION, the product is over PRIMES dividing d, and the $*$ indicates that the GREATEST PRIME FACTOR of d is omitted from the product. It is also known that if d is RELATIVELY PRIME to 5077, then the denominator 7000 in (8) can be replaced by 55.

The *Mathematica* function NumberTheory‘NumberTheoryFunctions‘ClassNumber[n] gives the class number $h(d)$ for d a NEGATIVE SQUAREFREE number OF THE FORM $4k + 1$.

GAUSS'S CLASS NUMBER PROBLEM asks to determine a complete list of fundamental DISCRIMINANTS $-d$ such that the CLASS NUMBER is given by $h(-d) = n$ for a given n. This problem has been solved for $n \leq 7$ and ODD $n \leq 23$. Gauss conjectured that the class number $h(-d)$ of an IMAGINARY QUADRATIC FIELD with DISCRIMINANT $-d$ tends to infinity with d, an assertion now known as GAUSS'S CLASS NUMBER CONJECTURE.

The discriminants d having $h(-d) = 1, 2, 3, 4, 5, \ldots$ are Sloane's A014602 (Cohen 1993, p. 229; Cox 1997, p. 271), Sloane's A014603 (Cohen 1993, p. 229), Sloane's A006203 (Cohen 1993, p. 504), Sloane's A013658 (Cohen 1993, p. 229), Sloane's A046002, Sloane's A046003, ... The complete set of negative discriminants having class numbers 1– and ODD 7–3 are known. Buell (1977) gives the smallest and largest fundamental class numbers for $d < 4,000,000$, partitioned into EVEN discriminants, discriminants 1 (mod 8), and discriminants 5 (mod 8). Arno *et al.* (1993) give complete lists of values of d with $h(-d) = k$ for ODD $k = 5, 7, 9, \ldots, 23$. Wagner gives complete lists of values for $k = 5$, 6, and 7.

Lists of NEGATIVE discriminants corresponding to IMAGINARY QUADRATIC FIELDS $\mathbb{Q}(\sqrt{-d(n)})$ having small class numbers $h(-d)$ are given in the table below. In the table, N is the number of "fundamental" values of $-d$ with a given class number $h(-d)$, where "fundamental" means that $-d$ is not divisible by any SQUARE NUMBER s^2 such that $h(-d/s^2) < h(-d)$. For example, although $h(-63) = 2$, -63 is not a fundamental discriminant since $63 = 3^2 \cdot 7$ and $h(-63/3^2) = h(-7) = 1 < h(-63)$. EVEN values $8 \leq h(-d) \leq 24$ have been computed by Weisstein. The number of negative discriminants having class number 1, 2, 3, ... are 9, 18, 16, 54, 25, 51, 31, ... (Sloane's A046125). The largest negative discriminants having class numbers 1, 2, 3, ... are 163, 427, 907, 1555, 2683, ... (Sloane's A038552).

The following table lists the numbers having class numbers $h \leq 25$. The search was terminated at 50000, 70000, 90000, and 90000 for class numbers 18, 20, 22,

and 24, respectively. As far as I know, analytic upper bounds are not currently known for these cases.

The table below gives lists of POSITIVE fundamental discriminants d having small class numbers $h(d)$, corresponding to REAL QUADRATIC FIELDS. All POSITIVE SQUAREFREE values of $d \leq 97$ (for which the KRONECKER SYMBOL is defined) are included.

$h(d)$	d
1	5, 13, 17, 21, 29, 37, 41, 53, 57, 61, 69, 73, 77
2	65

The POSITIVE d for which $h(d=1)$ is given by Sloane's A014539.

Class Number Formula

A class number formula is a finite series giving exactly the CLASS NUMBER of a RING. For a RING of quadratic integers, the class number is denoted $h(d)$, where d is the discriminant. A class number formula is known for the full ring of cyclotomic integers, as well as for any subring of the cyclotomic integers. This formula includes the quadratic case as well as many cubic and higher-order RINGS.

See also CLASS NUMBER, RING

Class Representative

A set of class representatives is a SUBSET of X which contains exactly one element from each EQUIVALENCE CLASS.

See also EQUIVALENCE CLASS

Classical Algebraic Geometry

Classical algebraic geometry is the study of ALGEBRAIC VARIETIES, both AFFINE VARIETIES in $\mathbb{C}^n$ and PROJECTIVE VARIETIES in $\mathbb{C}¶^n$. The original motivation was to study systems of polynomials and their roots.

See also ALGEBRAIC GEOMETRY, ALGEBRAIC VARIETY, POLYNOMIAL

Classical Canonical Form

JORDAN CANONICAL FORM

Classical Groups

The four following types of GROUPS,

1. LINEAR GROUPS,
2. ORTHOGONAL GROUPS,
3. SYMPLECTIC GROUPS, and
4. UNITARY GROUPS,

which were studied before more exotic types of groups (such as the SPORADIC GROUPS) were discovered.

See also GROUP, GROUP THEORY, LINEAR GROUP, ORTHOGONAL GROUP, SIMPLE GROUP, SYMPLECTIC GROUP, UNITARY GROUP

Classification

The classification of a collection of objects generally means that a list has been constructed with exactly one member from each ISOMORPHISM type among the objects, and that tools and techniques can effectively be used to identify any combinatorially given object with its unique representative in the list. Examples of mathematical objects which have been classified include the finite SIMPLE GROUPS and 2-MANIFOLDS but not, for example, KNOTS.

See also ENUMERATION PROBLEM

Classification Theorem

CLASSIFICATION THEOREM OF FINITE GROUPS, CLASSIFICATION THEOREM OF SURFACES

Classification Theorem of Finite Groups

The classification theorem of FINITE SIMPLE GROUPS, also known as the ENORMOUS THEOREM, which states that the FINITE SIMPLE GROUPS can be classified completely into

1. Cyclic groups $\mathbb{Z}_p$ of prime order,
2. Alternating groups A_n of degree at least five,
3. Lie-type Chevalley groups $PSL(n, q)$, $PSU(n, q)$, $PsP(2n, q)$, and $P\Omega^{\epsilon}(n, q)$,
4. Lie-type (twisted Chevalley groups or the Tits group) ${}^3D_4(q)$, $E_6(q)$, $E_7(q)$, $E_8(q)$, $F_4(q)$, ${}^2F_4(2^n)'$, $G_2(q)$, ${}^2G_2(3^n)$, ${}^2B(2^n)$,
5. Sporadic groups M_{11}, M_{12}, M_{22}, M_{23}, M_{24}, $J_2 = HJ$, Suz, HS, McL, Co_3, Co_2, Co_1, He, Fi_{22}, Fi_{23}, Fi'_{24}, HN, Th, B, M, J_1, $O'N$, J_3, Ly, Ru, J_4.

The "proof" of this theorem is spread throughout the mathematical literature and is estimated to be approximately 15,000 pages in length.

Classification Theorem of Surfaces

All closed surfaces, despite their seemingly diverse forms, are topologically equivalent to spheres with some number of handles or cross-caps. The traditional proof follows Seifert and Threlfall (1980), but Conway's so-called "zero-irrelevancy" ("ZIP") provides a more streamlined approach (Francis and Weeks 1999).

See also Cross-Cap, Handle

Clausen Formula

Clausen's ${}_4F_3$ identity

$$ {}_4F_3\left(\begin{matrix} a, b, c, d \\ e, f, g \end{matrix}; 1\right) = \frac{(2a)_{|d|}(a+b)_{|d|}(2b)_{|d|}}{(2a+2b)_{|d|}a_{|d|}b_{|d|}}, \qquad (1) $$

holds for $a+b+c-d = 1/2$, $e = a+b+1/2$, $a+f = d+1 = b+g$, where d a nonpositive integer and $(a)_n$ is the Pochhammer symbol (Petkovsek *et al.* 1996). Closely related identities include

$$ {}_4F_3 = \left[\begin{matrix} \frac{1}{2}a, \frac{1}{2}(a+1), b+n, -n \\ \frac{1}{2}b, \frac{1}{2}(b+1), a+1 \end{matrix}; 1\right] = \frac{(b-a)_n}{(b)_n} \qquad (2) $$

and

$$ {}_4F_3\left(\begin{matrix} \frac{1}{2}a, \frac{1}{2}(a+1), b+n, -n \\ \frac{1}{2}(b+1), \frac{1}{2}(b+2), a \end{matrix}; 1\right] = \frac{(b-a+1)_n}{(b+1)_{n-1}(b+2n)} \qquad (3) $$

(Bailey 1935; Slater 1966, p. 245; Andrews and Burge 1993)

Another identity ascribed to Clausen which involves the hypergeometric function ${}_2F_1(a, b; c; z)$ and the generalized hypergeometric function ${}_3F_2(a, b, c; d, e; z)$ is given by

$$ \left[{}_2F_1\left(\begin{matrix} a, b \\ a+b+\frac{1}{2} \end{matrix}; x\right)\right]^2 = {}_3F_2\left(\begin{matrix} 2a, a+b, 2b \\ a+b+\frac{1}{2}, 2a+2b \end{matrix}; x\right) \qquad (4) $$

(Clausen 1828; Bailey 1935, p. 86; Hardy 1999, p. 106).

Clausen Function

Define

$$ S_n(x) \equiv \sum_{k=1}^{\infty} \frac{\sin(kx)}{k^n} \qquad (1) $$

$$ C_n(x) \equiv \sum_{k=1}^{\infty} \frac{\cos(kx)}{k^n}, \qquad (2) $$

and write

$$Cl_n(x) \equiv \begin{cases} S_n(x) = \sum_{k=1}^{\infty} \frac{\sin(kx)}{k^n} & n \text{ even} \\ C_n(x) = \sum_{k=1}^{\infty} \frac{\cos(kx)}{k^n} & n \text{ odd.} \end{cases} \tag{3}$$

Then the Clausen function $Cl_n(x)$ can be given symbolically in terms of the POLYLOGARITHM as

$$Cl_n(x) = \begin{cases} \frac{1}{2}\, i[\mathrm{Li}_n(e^{-ix}) - \mathrm{Li}_n(e^{ix})] & n \text{ even} \\ \frac{1}{2}\, [\mathrm{Li}_n(e^{-ix}) + \mathrm{Li}_n(e^{ix})] & n \text{ odd.} \end{cases} \tag{4}$$

For $n = 1$, the function takes on the special form

$$Cl_1(x) = C_1(x) = -\ln|2 \sin(\tfrac{1}{2} x)| \tag{5}$$

and for $n = 2$, it becomes CLAUSEN'S INTEGRAL

$$Cl_2(x) = S_2(x) = -\int_0^x \ln[2 \sin(\tfrac{1}{2} t)]\, dt. \tag{6}$$

The symbolic sums of opposite parity are summable symbolically, and the first few are given by

$$C_2(x) = \tfrac{1}{6}\pi^2 - \tfrac{1}{2}\pi x + \tfrac{1}{4}x^2 \tag{7}$$

$$C_4(x) = \tfrac{1}{90} - \tfrac{1}{12}\pi^2 x^2 + \tfrac{1}{12}\pi x^3 - \tfrac{1}{48}x^4 \tag{8}$$

$$S_1(x) = \tfrac{1}{2}(\pi - x) \tag{9}$$

$$S_3(x) = \tfrac{1}{6}\pi^2 x - \tfrac{1}{4}\pi x^2 + \tfrac{1}{12}x^3 \tag{10}$$

$$S_5(x) = \tfrac{1}{90}\pi^4 x - \tfrac{1}{36}\pi^2 x^3 + \tfrac{1}{48}\pi x^4 - \tfrac{1}{240}x^5 \tag{11}$$

for $0 \le x \le 2\pi$ (Abramowitz and Stegun 1972).

Clebsch Diagonal Cubic

A CUBIC ALGEBRAIC SURFACE given by the equation

$$x_0^3+x_1^3+x_2^3+x_3^3+x_4^3=0, \quad (1)$$

with the added constraint

$$x_0+x_1+x_2+x_3+x_4=0. \quad (2)$$

The implicit equation obtained by taking the plane at infinity as $x_0+x_1+x_2+x_3/2$ is

$$81(x^3+y^3+z^3)-189(x^2y+x^2z+y^2x+y^2z+z^2x+z^2y)$$
$$+54xyz+126(xy+xz+yz)-9(x^2+y^2+z^2)$$
$$-9(x+y+z)+1=0 \quad (3)$$

(Hunt, Nordstrand). On Clebsch's diagonal surface, all 27 of the complex lines (SOLOMON'S SEAL LINES) present on a general smooth CUBIC SURFACE are real. In addition, there are 10 points on the surface where 3 of the 27 lines meet. These points are called ECKARDT POINTS (Fischer 1986, Hunt), and the Clebsch diagonal surface is the unique CUBIC SURFACE containing 10 such points (Hunt).

If one of the variables describing Clebsch's diagonal surface is dropped, leaving the equations

$$x_0^3+x_1^3+x_2^3+x_3^3=0, \quad (4)$$

$$x_0+x_1+x_2+x_3=0, \quad (5)$$

the equations degenerate into two intersecting PLANES given by the equation

$$(x+y)(x+z)(y+z)=0. \quad (6)$$

See also CUBIC SURFACE, ECKARDT POINT

Clebsch-Aronhold Notation

A notation used to describe curves. The fundamental principle of Clebsch-Aronhold notation states that if each of a number of forms be replaced by a POWER of a linear form in the same number of variables equal to the order of the given form, and if a sufficient number of equivalent symbols are introduced by the ARONHOLD PROCESS so that no actual COEFFICIENT appears except to the first degree, then every identical relation holding for the new specialized forms holds for the general ones.

ClebschGordan

CLEBSCH-GORDAN COEFFICIENT

Clebsch-Gordan Coefficient

A mathematical symbol used to integrate products of three SPHERICAL HARMONICS. Clebsch-Gordan coefficients commonly arise in applications involving the addition of angular momentum in quantum mechanics. If products of more than three SPHERICAL HARMONICS are desired, then a generalization known as WIGNER 6J-SYMBOLS or WIGNER 9J-SYMBOLS is used. The Clebsch-Gordan coefficients are written

$$C^j_{m_1m_2} = (j_1j_2m_1m_2|j_1j_2jm) \tag{1}$$

and are defined by

$$\Psi_{JM} = \sum_{M=M_1+M_2} C^J_{M_1M_2}\Psi_{M_1M_2}, \tag{2}$$

where $J \equiv J_1 + J_2$.

The coefficients are subject to the restrictions that (j_1, j_2, j) be positive integers or half-integers, j_1+j_2+j is an integer, (m_1, m_2, m) are positive or negative integers or half integers,

$$j_1 + j_2 - j \geq 0 \tag{3}$$

$$j_1 - j_2 + j \geq 0 \tag{4}$$

$$-j_1 + j_2 + j \geq 0, \tag{5}$$

and $-|j_1| \leq m_1 \leq |j_1|$, $-|j_2| \leq m_2 \leq |j_2|$, and $-|j| \leq m \leq |j|$ (Abramowitz and Stegun 1972, p. 1006). In addition, by use of symmetry relations, coefficients may always be put in the standard form $j_1 < j_2 < j$ and $m \geq 0$.

The Clebsch-Gordan coefficients are implemented in *Mathematica* as `ClebschGordan[{j1, m1}, {j2, m2}, {j, m}]` (assumed to be in standard form) and satisfy

$$(j_1j_2m_1m_2|j_1j_2jm) = 0 \quad \text{for } m_1 + m_2 \neq m \tag{6}$$

and are

The Clebsch-Gordan coefficients are sometimes expressed using the related RACAH V-COEFFICIENTS,

$$V(j_1j_2j;\ m_1m_2m) \tag{7}$$

or WIGNER 3J-SYMBOLS. Connections among the three are

$$(j_1j_2m_1m_2|j_1j_2jm) = (-1)^{m+j_1-j_2}\sqrt{2j+1}\begin{pmatrix} j_1 & j_2 & j \\ m_1 & m_2 & -m \end{pmatrix} \tag{8}$$

$$(j_1j_2m_1m_2|j_1j_2jm) = (-1)^{j+m}\sqrt{2j+1}V(j_1j_2j;\ m_1m_2-m) \tag{9}$$

$$V(j_1j_2j;\ m_1m_2m) = (-1)^{-j_1+j_2+j}\begin{pmatrix} j_1 & j_2 & j_1 \\ m_1 & m_2 & m_2 \end{pmatrix}. \tag{10}$$

They have the symmetry

$$(j_1j_2m_1m_2|j_1j_2jm) = (-1)^{j_1+j_2-j}(j_2j_1m_2m_1|j_2j_1jm), \tag{11}$$

and obey the orthogonality relationships

$$\sum_{j,\ m} (j_1j_2m_1m_2|j_1j_2jm)(j_1j_2jm|j_1j_2m_1'm_2') = \delta_{m_1m_1'}\delta_{m_2m_2'} \tag{12}$$

$$\sum_{m_1,\ m_2} (j_1j_2m_1m_2|j_1j_2jm)(j_1j_2j'm'|j_1j_2m_1m_2) = \delta_{jj'}\delta_{mm'}. \tag{13}$$

Clement Matrix

KAC MATRIX

Clenshaw Recurrence Formula

The downward Clenshaw recurrence formula evaluates a sum of products of indexed COEFFICIENTS by functions which obey a RECURRENCE RELATION. If

$$f(x) = \sum_{k=0}^{N} c_kF_k(x)$$

and

$$F_{n+1}(x) = \alpha(n,\ x)F_n(x) + \beta(n,\ x)F_{n-1}(x),$$

where the c_ks are known, then define

$$y_{N+2} = y_{N+1} = 0$$

$$y_k = \alpha(k, x)y_{k+1} + \beta(k+1, x)y_{k+2} + c_k$$

for $k = N, N-1, \ldots$ and solve backwards to obtain y_2 and y_1.

$$c_k = y_k - \alpha(k, x)y_{k+1} - \beta(k+1, x)y_{k+2}$$

$$\begin{aligned} f(x) &= \sum_{k=0}^{N} c_k F_k(x) \\ &= c_0 F_0(x) + [y_1 - \alpha(1, x)y_2 - \beta(2, x)y_3]F_1(x) \\ &\quad + [y_2 - \alpha(2, x)y_3 - \beta(3, x)y_4]F_2(x) \\ &\quad + [y_3 - \alpha(3, x)y_4 - \beta(4, x)y_5]F_3(x) \\ &\quad + [y_4 - \alpha(4, x)y_5 - \beta(5, x)y_6]F_4(x) + \ldots \\ &= c_0 F_0(x) + y_1 F_1(x) + y_2[F_2(x) - \alpha(1, x)F_1(x)] \\ &\quad + y_3[F_3(x) - \alpha(2, x)F_2(x) - \beta(2, x)] \\ &\quad + y_4[F_4(x) - \alpha(3, x)F_3(x) - \beta(3, x)] + \ldots \\ &= c_0 F_0(x) + y_2[\{\alpha(1, x)F_1(x) + \beta(1, x)F_0(x)\} \\ &\quad - \alpha(1, x)F_1(x)] + y_1 F_1(x) \\ &= c_0 F_0(x) + y_1 F_1(x) + \beta(1, x)F_0(x)y_2. \end{aligned}$$

The upward Clenshaw recurrence formula is

$$y_{-2} = y_{-1} = 0$$

$$y_k = \frac{1}{\beta(k+1, x)}[y_{k-2} - \alpha(k, x)y_{k-1} - c_k]$$

for $k = 0, 1, \ldots, N-1$.

$$f(x) = c_N F_N(x) - \beta(N, x)F_{N-1}(x)y_{N-1} - F_N(x)y_{N-2}.$$

Cliff Random Number Generator

A RANDOM NUMBER generator produced by iterating

$$X_{n+1} = |100 \ln X_n \pmod{1}|$$

for a SEED $X_0 = 0.1$. This simple generator passes the NOISE SPHERE test for randomness by showing no structure.

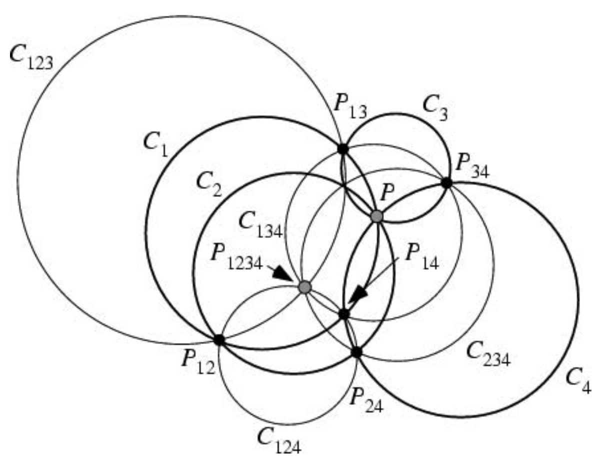
Clifford Algebra

Let V be an n-D linear SPACE over a FIELD K, and let Q be a QUADRATIC FORM on V. A Clifford algebra is then defined over the $T(V)/I(Q)$, where $T(V)$ is the tensor algebra over V and I is a particular IDEAL of $T(V)$.



Clifford algebraists call their higher dimensional numbers HYPERCOMPLEX even though they do not share all the properties of complex numbers and no classical function theory can be constructed over them.

See also HYPERCOMPLEX NUMBER, QUATERNION

Clifford's Circle Theorem

Let C_1, C_2, C_3, and C_4 be four CIRCLES of GENERAL POSITION through a point P. Let P_{ij} be the second intersection of the CIRCLES C_i and C_j. Let C_{ijk} be the CIRCLE $P_{ij}P_{ik}P_{jk}$. Then the four CIRCLES C_{234}, C_{134}, C_{124}, and C_{123} all pass through the point P_{1234}. Similarly, let C_5 be a fifth CIRCLE through P. Then the five points P_{2345}, P_{1345}, P_{1245}, P_{1235} and P_{1234} all lie on one CIRCLE C_{12345}. And so on.

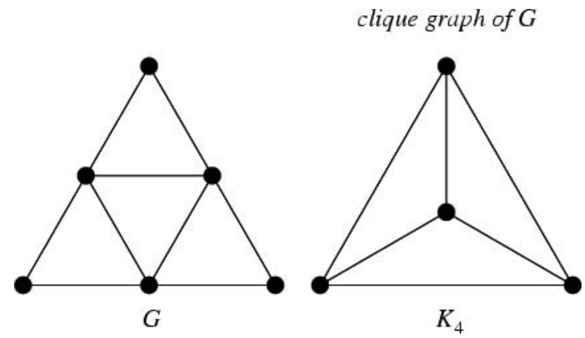
Clique

cliques

A clique of a GRAPH is its maximal COMPLETE SUBGRAPH (Harary 1994, p. 20), although some authors define a clique as any COMPLETE SUBGRAPH and then refer to "maximum cliques" (Skiena 1990, p. 217). The problem of finding the size of a clique for a given GRAPH is an NP-COMPLETE PROBLEM (Skiena 1997).



Cliques arise in a number of areas of GRAPH THEORY and combinatorics, including the theory of ERROR-CORRECTING CODES. The command `MaximumClique[g]` in the *Mathematica* add-on package `DiscreteMath'Combinatorica'` (which can be loaded with the command `<<DiscreteMath'`) finds the size of the largest clique in a given GRAPH.

The number of graphs on n nodes having 3 cliques are 0, 0, 1, 4, 12, 31, 67, ... (Sloane's A005289). A COMPLETE K-PARTITE GRAPH has maximum clique size k. The largest order n graph which does not contain the COMPLETE GRAPH K_p as a SUBGRAPH is called the TURÁN'S GRAPH $T_{n,p}$ (Skiena 1990, p. 218).

Clique Graph

The clique graph of a given GRAPH G is the GRAPH INTERSECTION of the family of CLIQUES of G. A GRAPH G is a clique graph IFF it contains a family F of COMPLETE SUBGRAPHS whose GRAPH UNION is G, such that whenever every pair of such complete graphs in some subfamily F' has a nonempty graph intersection, the intersection of all members of F' is not empty (Harary 1994, p. 20).

See also CLIQUE, CLIQUE NUMBER, COMPLETE GRAPH

References
Harary, F. *Graph Theory.* Reading, MA: Addison-Wesley, 1994.

Clique Number

The number of VERTICES in the largest CLIQUE of G, denoted $\omega(G)$. For an arbitrary GRAPH,

$$\omega(G) \geq \sum_{i=1}^{n} \frac{1}{n - d_i},$$

where d_i is the DEGREE of VERTEX i. The following table gives the number $N_k(n)$ of n-node graphs having clique number k for small k.

k	Sloane	$N_k(n)$
1		1, 1, 1, 1, 1, 1, ...

2	A052450	0, 1, 2, 6, 13, 37, 106, ...
3	A052451	0, 0, 1, 3, 15, 82, 578, ...
4	A052452	0, 0, 0, 1, 4, 30, 301, ...
5		0, 0, 0, 0, 1, 5, 51, ...
6		0, 0, 0, 0, 0, 1, 6, ...

Clock Arithmetic

CONGRUENCE

Clock Prime

A prime number obtained by reading digits around an analog clock. In a clockwise directions, the primes are 2, 3, 5, 7, 11, 23, 67, 89, 4567, 23456789, 23456789101112123, ... (Sloane's A036342). In a counterclockwise direction, the primes are 2, 3, 5, 7, 11, 43, 109, 10987, 76543, 6543211211, 4321121110987, ... (Sloane's A036342). In either direction, the primes are 2, 3, 5, 7, 11, 23, 43, 67, 89, 109, 4567, 10987, 76543, 23456789, 6543211211, ... (Sloane's A036344).

On a 24-hour digital clock, there are 211 possible prime values: 2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47, 53, 59, 101, ... (Sloane's A050246).

Close Packing

SPHERE PACKING

Closed

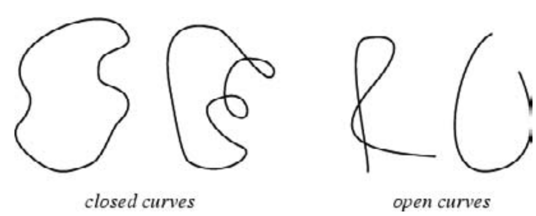
A mathematical structure A is said to be closed under an operation $+$ if, whenever a and b are both elements of A, then so is $a+b$.

A mathematical object taken together with its boundary is also called closed. For example, while the interior of a SPHERE is an OPEN BALL, the interior together with the sphere itself is a CLOSED BALL.

See also CLOSED BALL, CLOSED CURVE, CLOSED DISK, CLOSED FORM, CLOSURE (TOPOLOGY)

Closed Ball

The closed ball with center $\mathbf{x}$ and radius r is defined by



$$B_r(\mathbf{x}) = \{\mathbf{y} : |\mathbf{y} - \mathbf{x}| \leq r\}.$$

Closed Curve Problem

Find NECESSARY and SUFFICIENT conditions that determine when the integral curve of two periodic functions $\kappa(s)$ and $\tau(s)$ with the same period L is a CLOSED CURVE.

Closed Disk

An n-D closed disk of RADIUS r is the collection of points of distance $\leq r$ from a fixed point in EUCLIDEAN n-space. Krantz (1999, p. 3) uses the symbol $\bar{D}(x, r)$ to denote the closed disk, and $\bar{D} = \bar{D}(\mathbf{0}, 1)$ to denote the unit closed disk centered at the origin

See also DISK, OPEN DISK

Closed Form

A discrete FUNCTION $A(n, k)$ is called closed form (or sometimes "hypergeometric") in two variables if the ratios $A(n+1, k)/A(n, k)$ and $A(n, k+1)/A(n, k)$ are both RATIONAL FUNCTIONS. A pair of closed form functions (F, G) is said to be a WILF-ZEILBERGER PAIR if

$$F(n+1, k) - F(n, k) = G(n, k+1) - G(n, k).$$

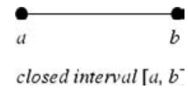
Closed Graph Theorem



A linear OPERATOR between two BANACH SPACES is continuous IFF it has a "closed" graph.

See also BANACH SPACE

References

Zeidler, E. *Applied Functional Analysis: Applications to Mathematical Physics.* New York: Springer-Verlag, 1995.

Closed Interval

An INTERVAL which includes its LIMIT POINTS. If the endpoints of the interval are FINITE numbers a and b, then the INTERVAL is denoted $[a, b]$. If one of the endpoints is $\pm\infty$, then the interval still contains all of its LIMIT POINTS, so $[a, \infty)$ and $(-\infty, b]$ are also closed intervals.

See also CLOSED BALL, CLOSED DISK, CLOSED SET, HALF-CLOSED INTERVAL, INTERVAL, OPEN INTERVAL

Closed Manifold

A COMPACT MANIFOLD without boundary.

See also OPEN MANIFOLD

Closed Set

There are several equivalent definitions of a closed SET. A SET S is closed if

1. The COMPLEMENT of S is an OPEN SET,
2. S is its own CLOSURE,
3. Sequences/nets/filters in S which converge do so within S,
4. Every point outside S has a NEIGHBORHOOD disjoint from S.

The POINT-SET TOPOLOGICAL definition of a closed set is a set which contains all of its LIMIT POINTS. Therefore, a closed set C is one for which, whatever point x is picked outside of C, x can always be isolated in some OPEN SET which doesn't touch C.

The most commonly encountered closed sets are the CLOSED INTERVAL, closed path, CLOSED DISK, interior of a closed path together with the path itself, and CLOSED BALL. The CANTOR SET is an unusual closed set in the sense that it consists entirely of BOUNDARY POINTS (and is nowhere DENSE, so it has LEBESGUE MEASURE 0).

It is possible for a set to be neither OPEN nor closed, e.g., the HALF-CLOSED INTERVAL $(0, 1]$.

Munkres, J. R. *Elements of Algebraic Topology.* Perseus Press, 1993.

Closed Subgroup

A SUBSET of a TOPOLOGICAL GROUP which is CLOSED as a SUBSET and also a SUBGROUP.

See also EFFECTIVE ACTION, FREE ACTION, GROUP, ISOTROPY GROUP, MATRIX GROUP, ORBIT (GROUP), QUOTIENT SPACE (LIE GROUP), REPRESENTATION, TOPOLOGICAL GROUP, TRANSITIVE

Closure (Set)

A SET S and a BINARY OPERATOR * are said to exhibit closure if applying the BINARY OPERATOR to two elements S returns a value which is itself a member of S.

The term "closure" is also used to refer to a "closed" version of a given set. The closure of a SET can be defined in several equivalent ways, including

1. The SET plus its LIMIT POINTS, also called "boundary" points, the union of which is also called the "frontier."
2. The unique smallest CLOSED SET containing the given SET.
3. The COMPLEMENT of the interior of the COMPLEMENT of the set.
4. The collection of all points such that every NEIGHBORHOOD of these points intersects the original SET in a nonempty SET.

In topologies where the T2-SEPARATION AXIOM is assumed, the closure of a finite SET S is S itself.

See also BINARY OPERATOR, BOUNDARY SET, CLOSURE (TOPOLOGY), CONNECTED SET, EXISTENTIAL CLOSURE, REFLEXIVE CLOSURE, TIGHT CLOSURE, TRANSITIVE CLOSURE

References

Croft, H. T.; Falconer, K. J.; and Guy, R. K. *Unsolved Problems in Geometry.* New York: Springer-Verlag, p. 2, 1991.

Closure (Topology)

The closure of a set A is the smallest closed set containing A. Closed sets are CLOSED under arbitrary intersection, so it is also the intersection of all closed sets containing A. Typically, it is just A with all of its ACCUMULATION POINTS.

See also CLOSED SET, CLOSURE (SET), SEQUENCE, TOPOLOGY

Closure Relation

$$\delta(x-t)=\sum_{n=0}^{\infty} \phi_n(x)\phi_n(t),$$

where $\delta(x)$ is the DELTA FUNCTION.

Stauffer, D. and Aharony, A. *Introduction to Percolation Theory, 2nd ed.* London: Taylor & Francis, 1992.

Cluster Perimeter

The number of empty neighbors of a CLUSTER.

See also PERIMETER POLYNOMIAL

Cluster Prime

An ODD PRIME p is called a cluster prime if every EVEN positive integer less than $p-2$ can be written as a difference of two primes $q-q'$, where $q,\ q' \le p$. The first 23 odd primes 3, 5, 7, ..., 89 are all cluster primes. The first few odd primes that are not cluster primes are 97, 127, 149, 191, 211, ... (Sloane's A038133).

The numbers of cluster primes less than 10^1, 10^2, ... are 23, 99, 420, 1807, ... (Sloane's A039506), and the corresponding numbers of noncluster primes are 0, 1, 68, 808, 7784, ... (Sloane's A039507). It is not known if there are infinitely many cluster primes, but Blecksmith *et al.* (1999) show that for every positive integer s, there is a bound $x_0 = x_x(s)$ such that if $x \ge x_0$, then

$$\pi_c(x) < \frac{x}{(\ln x)^s},$$

where $\pi_c(x)$ is the number of cluster primes not exceeding x. Blecksmith *et al.* (1999) also show that the sum of the reciprocals of the cluster primes is finite.

See also PRIME CONSTELLATION

C-Matrix

Any SYMMETRIC MATRIX ($C^T = C$) or SKEW SYMMETRIC MATRIX ($C^T = -C$) C_n with diagonal elements 0 and others $\pm$ 1 satisfying

$$CC^T = (n-1)I,$$

where I is the IDENTITY MATRIX, is known as a C-matrix (Ball and Coxeter 1987). There are two symmetric C-matrices of order 2,

$$\begin{bmatrix} 0 & -1 \\ -1 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$$

and two antisymmetric C-matrices of order 2,

$$\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}.$$

Further examples include

$$C_4 = \begin{bmatrix} 0 & + & + & + \\ - & 0 & - & + \\ - & + & 0 & - \\ - & - & + & 0 \end{bmatrix}$$

$$C_6 = \begin{bmatrix} 0 & + & + & + & + & + \\ + & 0 & + & - & - & + \\ + & + & 0 & + & - & - \\ + & - & + & 0 & + & - \\ + & - & - & + & 0 & + \\ + & + & - & - & + & 0 \end{bmatrix}$$

There are no symmetric C-matrices of order 4 or 22 (Ball and Coxeter 1987, p. 309). The following table gives the number of C-matrices of orders $n = 1$, 2, ...

Type	Sloane Numbers
symmetric	0, 2, 0, 0, 0, 384, 0, 0, ...
antisymmetric	0, 2, 0, 16, 0, 0, 0, 30720, ...
total	0, 4, 0, 16, 0, 384, 0, 30720, ...

A C-matrix of an odd prime power order may be constructed using a general method due to Paley (Paley 1933, Ball and Coxeter 1987).

Coanalytic Set

A DEFINABLE SET which is the complement of an ANALYTIC SET.

See also ANALYTIC SET

Coastline Paradox

Determining the length of a country's coastline is not as simple as it first appears, as first considered by L. F. Richardson (1881–953). In fact, the answer depends on the length of the RULER you use for the measurements. A shorter RULER measures more of the sinuosity of bays and inlets than a larger one, so the estimated length continues to increase as the RULER length decreases.

In fact, a coastline is an example of a FRACTAL, and plotting the length of the RULER versus the measured length of the coastline on a log-log plot gives a straight line, the slope of which is the FRACTAL

DIMENSION of the coastline (and will be a number between 1 and 2).

Coaxal Circles

CIRCLES which share a RADICAL LINE with a given circle are said to be coaxal. The centers of coaxal circles are COLLINEAR, and the collection of all coaxal circles is called a pencil of coaxal circles (Coxeter and Greitzer 1967, p. 35). It is possible to combine the two types of coaxal systems illustrated above such that the sets are orthogonal.

Members of a COAXAL SYSTEM satisfy

$$x^2+y^2+2\lambda x+c=(x+\lambda)^2+y^2+c-\lambda^2=0$$

for values of λ. Picking $\lambda^2=c$ then gives the two circles

$$(x\pm\sqrt{c})^2+y^2=0$$

of zero RADIUS, known as POINT CIRCLES. The two point circles $(\pm\sqrt{c},\ 0)$, real or imaginary, are called the LIMITING POINTS.

Cobweb Equation

This entry contributed by RONALD M. AARTS

The simple first-order DIFFERENCE EQUATION

$$y_{t+1} - Ay_t = B, \quad (1)$$

where

$$A = -\frac{m_s}{m_d} \quad (2)$$

$$B = \frac{b_d - b_s}{m_d} \quad (3)$$

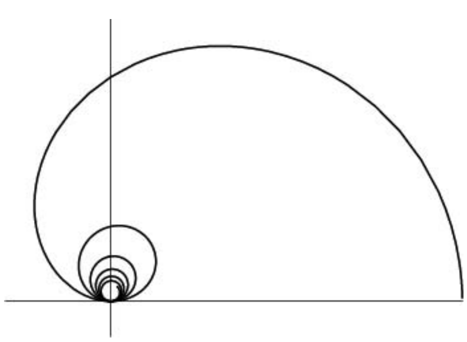
and

$$D_t = -m_d p_t + b_d \quad (4)$$

$$S_{t+1} = m_s p_t + b_s \quad (5)$$

are the price-demand and price-supply curves, where $-m_d$ and b_d represent the slope and D-intercept, respectively, for the demand curve, and m_s and b_s represent the corresponding constants for the supply curve (Ezekiel 1938, Goldberg 1986).

A class of behaviors related to this equation is known as "Cobweb phenomena" in economics.



See also DIFFERENCE EQUATION

Cochleoid

The cochleoid, whose name means "snail-form" in Latin, was first discussed by J. Peck in 1700 (MacTutor Archive). It has also been called the oui-ja board curve (Beyer 1987, p. 215). The points of contact of PARALLEL TANGENTS to the cochleoid lie on a STROPHOID.

In POLAR COORDINATES,

$$r = \frac{a \sin\theta}{\theta}. \quad (1)$$

In CARTESIAN COORDINATES,

$$(x^2 + y^2)\tan^{-1}\left(\frac{y}{x}\right) = ay. \quad (2)$$

The CURVATURE is

$$\kappa = \frac{2\sqrt{2}\theta^3[2\theta - \sin(2\theta)]}{[1 + 2\theta^2 - \cos(2\theta) - 2\theta\sin(2\theta)]^{3/2}}. \quad (3)$$

Cofinite Filter

This entry contributed by VIKTOR BENGTSSON

If S is an infinite set, then the collection $F_S = \{A \subseteq S : S - A \text{ is finite}\}$ is a FILTER called the cofinite (or Fréchet) filter on S.

See also FILTER, ULTRAFILTER

Cohen-Kung Theorem

Guarantees that the trajectory of LANGTON'S ANT is unbounded.

Cohomology

Cohomology is an invariant of a TOPOLOGICAL SPACE, formally "dual" to HOMOLOGY, and so it detects "holes" in a SPACE. Cohomology has more algebraic structure than HOMOLOGY, making it into a GRADED RING (with multiplication given by the so-called "CUP PRODUCT"), whereas HOMOLOGY is just a graded ABELIAN GROUP invariant of a SPACE.

A generalized homology or cohomology theory must satisfy all of the EILENBERG-STEENROD AXIOMS with the exception of the dimension axiom.

See also ALEKSANDROV-CECH COHOMOLOGY, ALEXANDER-SPANIER COHOMOLOGY, CECH COHOMOLOGY, CUP PRODUCT, DE RHAM COHOMOLOGY, DOLBEAULT COHOMOLOGY, GRADED ALGEBRA, HOMOLOGY (TOPOLOGY)

Cohomology Class

Coin Flipping

COIN TOSSING

Coin Paradox

After a half rotation of the coin on the left around the central coin (of the same RADIUS), the coin undergoes a complete rotation. In other words, a coin makes two complete rotations when rolled around the boundary of an identical coin. This fact is readily apparent in the generation of the CARDIOID as one disk rolling on another.

See also CARDIOID

Coin Problem

Let there be $n \geq 2$ INTEGERS $0 < a_1 < \ldots < a_n$ with $(a_1, a_2, \ldots, a_n) = 1$ (all RELATIVELY PRIME). For large enough $N = \Sigma_{i=1}^{n} a_i x_i$, there is a solution in NONNEGATIVE INTEGERS x_i. The greatest $N = g(a_1, a_2, \ldots, a_n)$ for which there is no solution is called the coin problem. Sylvester showed

$$g(a_1, a_2) = (a_1 - 1)(a_2 - 1) - 1,$$

and an explicit solution is known for $n = 3$, but no closed form solution is known for larger N.

References

Guy, R. K. "The Money-Changing Problem." §C7 in *Unsolved Problems in Number Theory, 2nd ed.* New York: Springer-Verlag, pp. 113–14, 1994.

Coin Tossing

An idealized coin consists of a circular disk of zero thickness which, when thrown in the air and allowed to fall, will rest with either side face up ("heads" H or "tails" T) with equal probability. A coin is therefore a two-sided DIE. Despite slight differences between the sides and NONZERO thickness of actual coins, the distribution of their tosses makes a good approximation to a $p = 1/2$ BERNOULLI DISTRIBUTION.

There are, however, some rather counterintuitive properties of coin tossing. For example, it is twice as likely that the triple TTH will be encountered before THT than after it, and three times as likely that THH will precede HHT. Furthermore, it is six times as likely that HTT will be the first of HTT, TTH, and TTT to occur (Honsberger 1979). There are also strings S of Hs and Ts that have the property that the expected wait $W(S_1)$ to see string S_1 is less than the expected wait $W(S_2)$ to see S_2, but the probability of seeing S_1 before seeing S_2 is less than 1/2 (Berlekamp *et al.* 1982; Gardner 1988). Examples include

1. $THTH$ and $HTHH$, for which $W(THTH) = 20$ and $W(HTHH) = 18$, but for which the probability that $THTH$ occurs before $HTHH$ is 9/14 (Gardner 1988, p. 64),
2. $W(TTHH) = W(THHH) = 16$, $W(HHH)$, but for which the probability that $TTHH$ occurs before HHH is 7/12, and for which the probability that $THHH$ occurs before HHH is 7/8 (Penney 1969; Gardner 1988, p. 66).

More amazingly still, *spinning* a penny instead of tossing it results in heads only about 30% of the time (Paulos 1995).

The study of RUNS of two or more identical tosses is well-developed, but a detailed treatment is surprisingly complicated given the simple nature of the underlying process.

Coincidence

A coincidence is a surprising concurrence of events, perceived as meaningfully related, with no apparent causal connection (Diaconis and Mosteller 1989). Given a large number events, extremely unlikely coincidences are possible–and perhaps even common. To quote Sherlock Holmes, "Amid the action and reaction of so dense a swarm of humanity, every possible combination of events may be expected to take place, and many a little problem will be presented which may be striking and bizarre..." (Conan Doyle 1988, p. 245).

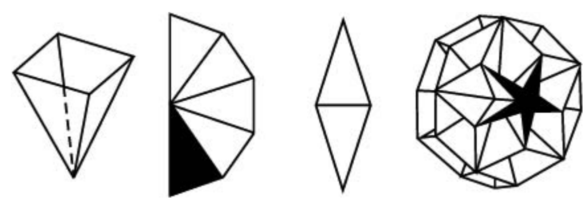
Coincident

Two LINES or plane CONGRUENT geometric figures which lie on top of each other are said to be coincident.

See also CONGRUENT, HOMOTHETIC, SIMILAR

Colatitude



The polar angle on a SPHERE measured from the North Pole instead of the equator. The angle ϕ in SPHERICAL COORDINATES is the COLATITUDE. It is related to the LATITUDE δ by $\phi = 90^\circ - \delta$.

See also LATITUDE, LONGITUDE, SPHERICAL COORDINATES

Colinear

COLLINEAR

Collapsoid

The collapsoids are a class of non-convex collapsible polyhedra. They can be constructed by replacing each edge of a DODECAHEDRON or ICOSAHEDRON by the diagonal of a pyramid (with base removed). Thirty such pyramids are then fitted together using tabs.

Collatz Problem

A problem posed by L. Collatz in 1937, also called the $3X+1$ MAPPING, HASSE'S ALGORITHM, KAKUTANI'S PROBLEM, SYRACUSE ALGORITHM, SYRACUSE PROBLEM, THWAITES CONJECTURE, and ULAM'S PROBLEM (Lagarias 1985). Thwaites (1996) has offered a £1000 reward for resolving the CONJECTURE. Let a_0 be an INTEGER. Then the Collatz problem asks if iterating

$$a_n = \begin{cases} \frac{1}{2} a_{n-1} & \text{for } a_{n-1} \text{ even} \\ 3a_{n-1}+1 & \text{for } a_{n-1} \text{ odd} \end{cases} \tag{1}$$

always returns to 1 for POSITIVE a_0. This question has been tested and found to be true for all numbers $\leq 3 \cdot 2^{53} \approx 2.702 \times 10^{16}$ (Oliveira e Silva 1999), im-

proving the earlier results of 10^{15} (Vardi 1991, p. 129) and 5.6×10^{13} (Leavens and Vermeulen 1992). The members of the SEQUENCE produced by the Collatz are sometimes known as HAILSTONE NUMBERS. Because of the difficulty in solving this problem, Erdos commented that "mathematics is not yet ready for such problems" (Lagarias 1985). If NEGATIVE numbers are included, there are four known cycles (excluding the trivial 0 cycle): (4, 2, 1), $(-2, -1)$, $(-5, -7, -10)$, and $(-17, -25, -37, -55, -82, -41, -61, -91, -136, -68, -34)$. The number of tripling steps needed to reach 1 for $n = 1, 2, \ldots$ are 0, 0, 2, 0, 1, 2, 5, 0, 6, ... (Sloane's A006667).

The Collatz problem was modified by Terras (1976, 1979), who asked if iterating

$$t_n = \begin{cases} \frac{1}{2} t_{n-1} & \text{for } t_{n-1} \text{ even} \\ \frac{1}{2}(3t_{n-1} + 1) & \text{for } t_{n-1} \text{ odd} \end{cases} \quad (2)$$

always returns to 1 for initial integer value t_0. If NEGATIVE numbers are included, there are 4 known cycles: (1, 2), (-1), $(-5, -7, -10)$, and $(-17, -25, -37, -55, -82, -41, -61, -91, -136, -68, -34)$. It is a special case of the "generalized Collatz problem" with $d = 2$, $m_0 = 1$, $m_1 = 3$, $r_0 = 0$, and $r_1 = -1$. Terras (1976, 1979) also proved that the set of INTEGERS $S_k \equiv \{n : n \text{ has stopping time} \leq k\}$ has a limiting asymptotic density $F(k)$, such that if $N_x(k)$ is the number of n such that $n \leq x$ and $\sigma(n) \leq k$, then the limit

$$F(k) = \lim_{x \to \infty} \frac{N_x(k)}{x}, \quad (3)$$

exists. Furthermore, $F(k) \to 1$ as $k \to \infty$, so almost all INTEGERS have a finite stopping time. Finally, for all $k \geq 1$,

$$1 - F(k) = \lim_{x \to \infty} \frac{N_x(k)}{x} \leq 2^{-nk}, \quad (4)$$

where

$$H(x) = -x \lg x - (1-x) \lg(1-x) \quad (5)$$

$$\theta = \frac{1}{\lg 3} \quad (6)$$

$$\eta = 1 - H(\theta) = 0.05004\ldots \quad (7)$$

(Lagarias 1985).

Conway proved that the original Collatz problem has no nontrivial cycles of length < 400. Lagarias (1985) showed that there are no nontrivial cycles with length $< 275{,}000$. Conway (1972) also proved that Collatz-type problems can be formally UNDECIDABLE.

A generalization of the COLLATZ PROBLEM lets $d \geq 2$ be a POSITIVE INTEGER and $m_0, \ldots, m_{d-1}$ be NONZERO INTEGERS. Also let $r_i \in \mathbb{Z}$ satisfy

$$r_i \equiv i m_i \pmod{d}. \quad (8)$$

Then

$$T(x) = \frac{m_i x - r_i}{d} \quad (9)$$

for $x \equiv i \pmod{d}$ defines a generalized Collatz mapping. An equivalent form is

$$T(x) = \left\lfloor \frac{m_i x}{d} \right\rfloor + X_i \quad (10)$$

for $x \equiv i \pmod{d}$ where $X_0, \ldots, X_{d-1}$ are INTEGERS and $\lfloor r \rfloor$ is the FLOOR FUNCTION. The problem is connected with ERGODIC THEORY and MARKOV CHAINS (Matthews 1995). Matthews (1995) obtained the following table for the mapping

$$T_k(x) = \begin{cases} \frac{1}{2} x & \text{for } x \equiv 0 \pmod{2} \\ \frac{1}{2}(3x + k) & \text{for } x \equiv 1 \pmod{2}, \end{cases} \quad (11)$$

where $k = T_{5^k}$.

k	# Cycles	Max. Cycle Length
0	5	27
1	10	34
2	13	118
3	17	118
4	19	118
5	21	165
6	23	433

Matthews and Watts (1984) proposed the following conjectures.

1. If $|m_0 \cdots m_{d-1}| < d^d$, then all trajectories $\{T^K(n)\}$ for $n \in \mathbb{Z}$ eventually cycle.
2. If $|m_0 \cdots m_{d-1}| > d^d$, then almost all trajectories $\{T^K(n)\}$ for $n \in \mathbb{Z}$ are divergent, except for an exceptional set of INTEGERS n satisfying

$$\#\{n \in S \mid -X \leq n < X\} = o(X).$$

3. The number of cycles is finite.
4. If the trajectory $\{T^K(n)\}$ for $n \in \mathbb{Z}$ is not eventually cyclic, then the iterates are uniformly distribution mod d^α for each $\alpha \geq 1$, with

$$\lim_{N \to \infty} \frac{1}{N+1} \operatorname{card}\{K \leq N \mid T^K(n) \equiv j \pmod{d^\alpha}\}$$

$$= d^{-\alpha} \qquad (12)$$

for $0 \le j \le d^{\alpha} - 1$.

Matthews believes that the map

$$T(x) = \begin{cases} 7x+3 & \text{for } x \equiv 0 \pmod 3 \\ \frac{1}{3}(7x+2) & \text{for } x \equiv 1 \pmod 3 \\ \frac{1}{3}(x-2) & \text{for } x \equiv 2 \pmod 3 \end{cases} \qquad (13)$$

will either reach 0 (mod 3) or will enter one of the cycles (−1) or (−2, −4), and offers a $100 (Australian?) prize for a proof.

Collinear

Three or more points P_1, P_2, P_3, ..., are said to be collinear if they lie on a single straight LINE L. A line on which points lie, especially if it is related to a geometric figure such as a TRIANGLE, is sometimes called an AXIS. Three points are collinear IFF the ratios of distances satisfy

$$x_2 - x_1 : y_2 - y_1 : z_2 - z_1 = x_3 - x_1 : y_3 - y_1 : z_3 - z_1.$$

Two points are trivially collinear since two points determine a LINE.

Let points P_1, P_2, and P_3 lie, one each, on the sides of a triangle $\Delta A_1A_2A_3$ or their extensions, and reflect these points about the midpoints of the triangle sides to obtain P_1', P_2', and P_3'. Then P_1', P_2', and P_3' are collinear IFF P_1, P_2, and P_3 are (Honsberger 1995).

Collineation

A transformation of the plane which transforms COLLINEAR points into COLLINEAR points. A projective collineation transforms every 1-D form projectively, and a perspective collineation is a collineation which leaves all lines through a point and points through a line invariant. In an ELATION, the center and axis are incident; in a HOMOLOGY they are not. For further discussion, see Coxeter (1969, p. 248).

Collision-Free Hash Function

A function H that maps an arbitrary length message M to a fixed length message digest MD is a collision-free hash function if

1. It is a ONE-WAY HASH FUNCTION.
2. It is hard to find two distinct messages (M', M) that hash to the same result $H(M') = H(M)$. More

precisely, any efficient algorithm (solving a P-PROBLEM) succeeds in finding such a collision with negligible probability (Russell 1992).

Cologarithm

The LOGARITHM of the RECIPROCAL of a number, equal to the NEGATIVE of the LOGARITHM of the number itself,

$$\operatorname{colog} x \equiv \log\left(\frac{1}{x}\right) = -\log x.$$

See also ANTILOGARITHM, LOGARITHM

Colon Product

Let **AB** and **CD** be DYADS. Their colon product is defined by

$$\mathbf{AB} : \mathbf{CD} \equiv \mathbf{C} \cdot \mathbf{AB} \cdot \mathbf{D} = (\mathbf{A} \cdot \mathbf{C})(\mathbf{B} \cdot \mathbf{D}).$$

See also DYAD

Colorable

Color each segment of a KNOT DIAGRAM using one of three colors. If

1. At any crossing, either the colors are all different or all the same, and
2. At least two colors are used,

then a KNOT is said to be colorable (or more specifically, THREE-COLORABLE). Colorability is invariant under REIDEMEISTER MOVES, and can be generalized. For instance, for five colors 0, 1, 2, 3, and 4, a KNOT is five-colorable if

1. at any crossing, three segments meet. If the overpass is numbered a and the two underpasses B and C, then $2a \equiv b + c \pmod 5$, and
2. at least two colors are used.

Colorability cannot always distinguish HANDEDNESS. For instance, three-colorability can distinguish the mirror images of the TREFOIL KNOT but not the FIGURE-OF-EIGHT KNOT. Five-colorability, on the other hand, distinguishes the MIRROR IMAGES of the FIGURE-OF-EIGHT KNOT but not the TREFOIL KNOT.

See also COLORING, WORM

Coloring

A coloring of plane regions, LINK segments, etc., is an assignment of a distinct labeling (which could be a number, letter, color, etc.) to each component. Coloring problems generally involve TOPOLOGICAL considerations (i.e., they depend on the abstract study of the arrangement of objects), and theorems about colorings, such as the famous FOUR-COLOR THEOREM, can be extremely difficult to prove.

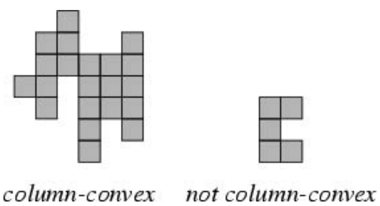
Columbian Number

SELF NUMBER

Column Space

See also ROW SPACE



Column Vector

An $m \times 1$ MATRIX

$$\begin{bmatrix} a_{11} \\ a_{21} \\ \vdots \\ a_{m1} \end{bmatrix}.$$

See also MATRIX, ROW VECTOR, VECTOR

Column-Convex Polyomino

A column-convex polyomino is a self-avoiding CONVEX POLYOMINO such that the intersection of any vertical line with the polyomino has at most two connected components. Column-convex polyominos are also called vertically convex polyominoes. A ROW-CONVEX POLYOMINO is similarly defined. The number $a(n)$ of column-convex n-polyominoes are given by the third-order RECURRENCE RELATION

$$a(n) = 5a(n-1) - 7a(n-2) + 4a(n-3)$$

with $a(1)=1$, $a(2)=2$, $a(3)=6$, and $a(4)=19$ (Hickerson 1999). The first few are 1, 2, 6, 19, 61, 196, 629, 2017, ... (Sloane's A001169). $a(n)$ has GENERATING FUNCTION

$$f(x) \frac{x(1-x)^3}{1-5x+7x^2-4x^3} = x + 2x^2 + 6x^3 + 19x^4 + \ldots.$$

Comb Function

SHAH FUNCTION

Combination

The number of ways of picking k *unordered* outcomes from n possibilities. Also known as the BINOMIAL COEFFICIENT or CHOICE NUMBER and read "n choose r."

$${}_nC_k \equiv \binom{n}{k} \equiv \frac{n!}{k!(n-k)!},$$

where $n!$ is a FACTORIAL (Uspensky 1937, p. 18). For example, there are $\binom{4}{2}=6$ combinations on $\{1, 2, 3, 4\}$, namely $\{1, 2\}$, $\{1, 3\}$, $\{1, 4\}$, $\{2, 3\}$, $\{2, 4\}$, and $\{3, 4\}$. These combinations are known as K-SUBSETS.

Muir (1960, p. 7) uses the nonstandard notations $(n)_k=\binom{n}{k}$ and $(\bar{n})_k=\binom{n-k}{k}$.

Combination Lock

Let a combination of n buttons be a SEQUENCE of disjoint nonempty SUBSETS of the SET $\{1, 2, \ldots, n\}$. If the number of possible combinations is denoted a_n, then a_n satisfies the RECURRENCE RELATION

$$a_n=\sum_{i=0}^{n-1}\binom{n}{n-i}a_i, \tag{1}$$

with $a_0=1$. This can also be written

$$a_n=\frac{d^n}{dx^n}\left(\frac{1}{2-e^x}\right)\bigg|_{x=0}=\tfrac{1}{2}\sum_{k=0}^{\infty}\frac{k^n}{2^k}, \tag{2}$$

where the definition $0^0=1$ has been used. Furthermore,

$$a_n\sum_{k=1}^{n}A_{n,\,k}2^{n-k}=\sum_{k=1}^{n}A_{n,\,k}2^{k-1}, \tag{3}$$

where $A_{n,\,k}$ are EULERIAN NUMBERS. In terms of the STIRLING NUMBERS OF THE SECOND KIND $s(n,\ k)$,

$$a_n=\sum_{k=1}^{n}k!s(n,\ k). \tag{4}$$

a_n can also be given in closed form as

$$a_n=\tfrac{1}{2}\operatorname{Li}_{-n}(\tfrac{1}{2}), \tag{5}$$

where $\operatorname{Li}_n(z)$ is the POLYLOGARITHM. The first few values of a_n for $n=1, 2, \ldots$ are 1, 3, 13, 75, 541, 4683, 47293, 545835, 7087261, 102247563, ... (Sloane's A000670).

The quantity

$$b_n\equiv\frac{a_n}{n!} \tag{6}$$

satisfies the inequality

$$\frac{1}{2(\ln 2)^n}\leq b_n\leq\frac{1}{(\ln 2)^n}. \tag{7}$$

Combinatorial Dual Graph

Let $m(G)$ be the cycle rank of a graph G, $m^*(G)$ be the cocycle rank, and the relative complement $G-H$ of a SUBGRAPH H of G be defined as that subgraph obtained by deleting the lines of H. Then a graph G^* is a combinatorial dual of G if there is a one-to-one correspondence between their sets of lines such that for any choice Y and Y^* of corresponding subsets of lines,

$$M^*(G-Y)=m^*(G)-m(\langle Y^*\rangle),$$

where $\langle Y^*\rangle$ is the subgraph of G^* with the line set Y^*.

Whitney showed that the GEOMETRIC DUAL GRAPH and combinatorial dual graph are equivalent (Harary 1994, p. 115), and so may simply be called "the" DUAL GRAPH. Also, a graph is PLANAR IFF it has a combinatorial dual (Harary 1994, p. 115).

Combinatorial Species

SPECIES

Combinatorial Topology

Combinatorial topology is a special type of ALGEBRAIC TOPOLOGY that uses COMBINATORIAL methods. For example, SIMPLICIAL HOMOLOGY is a combinatorial construction in ALGEBRAIC TOPOLOGY, so it belongs to combinatorial topology.

Comma

A typesetting symbol which has several distinct meanings in mathematics. It is used for a number of purposes.

1. To denote Boundaries between elements in a list, as in $\{1, 2, 3, \ldots\}$.
2. To delimit indices in the element of a MATRIX, as in $a_{i,j}$ (although it is frequently omitted when implied by context).
3. To indicate the COMMA DERIVATIVE of a TENSOR.
4. In place of a DECIMAL POINT in continental Europe, e.g., 3,14159.

See also COMMA DERIVATIVE, DECIMAL POINT

References

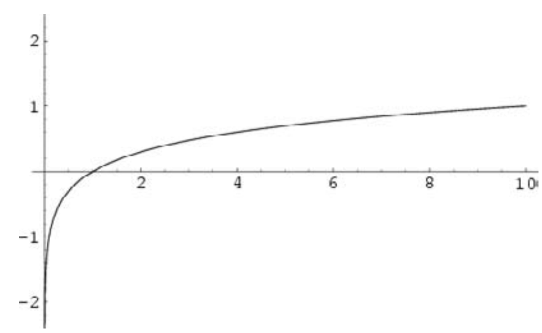
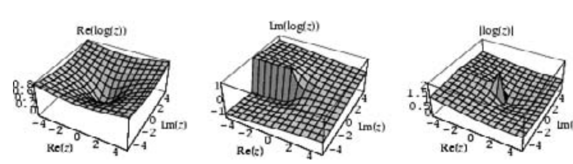
Common Cycloid



CYCLOID



Common Fraction

A FRACTION in which NUMERATOR and DENOMINATOR are both integers, as opposed to fractions. Common fractions are sometimes also called vulgar fractions.

See also COMPLEX FRACTION, FRACTION

Common Logarithm

The LOGARITHM in BASE 10. The notation $\log x$ is used by physicists, engineers, and calculator keypads to denote the common logarithm. However, mathematicians generally use the same symbol to mean the NATURAL LOGARITHM LN, $\ln x$. Worse still, in Russian literature the notation $\lg x$ is used to denote a base-10 logarithm, which conflicts with the use of the symbol LG to indicate the logarithm to base 2. To avoid all ambiguity, it is best to explicitly specify $\log_{10} x$ when the logarithm to base 10 is intended. In this work, $\log x = \log_{10} x$, $\ln x = \log_e x$ is used for the NATURAL

LOGARITHM, and $\lg x = \log_2 x$ is the logarithm to the base 2.

Hardy and Wright (1979, p. 8) assert that the common logarithm has "no mathematical interest." Common and natural logarithms can be expressed in terms of each other as

$$\ln x = \frac{\log_{10} x}{\log_{10} e}$$

$$\log_{10} x = \frac{\ln x}{\ln 10}.$$

See also LG, LN, LOGARITHM, NATURAL LOGARITHM

Common Residue

The value of b, where $a \equiv b \pmod m$, taken to be NONNEGATIVE and smaller than m.

See also MINIMAL RESIDUE, RESIDUE (CONGRUENCE)

Commutation Coefficient

A TENSOR-like coefficient which gives the difference between PARTIAL DERIVATIVES of two coordinates with respect to the other coordinate,

$$c_{\alpha\beta}^{\mu}\vec{e}_{\mu} = [\vec{e}_{\alpha}, \vec{e}_{\beta}] = \nabla_{\alpha}\vec{e}_{\beta} - \nabla_{\beta}\vec{e}_{\alpha}.$$

See also CONNECTION COEFFICIENT, PARTIAL DERIVATIVE

Commutative

Two elements x and y of a set S are said to be commutative under a binary operation $*$ if they satisfy

$$x * y = y * x.$$

Real numbers are commutative under addition

$$x + y = y + x$$

and multiplication

$$x \cdot y = y \cdot x.$$

See also ASSOCIATIVE, COMMUTE, COMMUTATIVE ALGEBRA, COMMUTATIVE MATRICES, COMMUTATIVE RING, DISTRIBUTIVE, TRANSITIVE

Commutative Algebra

Let A denote an $\mathbb{R}$-algebra, so that A is a VECTOR SPACE over R and

$$A \times A \to A \tag{1}$$

$$(x, y) \mapsto x \cdot y. \tag{2}$$

Now define

$$Z \equiv \{x \in A : x \cdot y = 0 \text{ for some } y \in A \neq 0\}, \tag{3}$$

where $0 \in Z$. An ASSOCIATIVE $\mathbb{R}$-algebra is commutative if $x \cdot y = y \cdot x$ for all $x, y \in A$. Similarly, a RING is commutative if the MULTIPLICATION operation is commutative, and a LIE ALGEBRA is commutative if the COMMUTATOR $[A, B]$ is 0 for every A and B in the LIE ALGEBRA.

COMMUTING MATRICES

Commutative Ring

A RING is commutative if the MULTIPLICATION operation is COMMUTATIVE.

See also COMMUTATIVE, RING

Commutator

Let $\tilde{A}$, $\tilde{B}$, ...be OPERATORS. Then the commutator of $\tilde{A}$ and $\tilde{B}$ is defined as

$$[\tilde{A}, \tilde{B}] \equiv \tilde{A}\tilde{B} - \tilde{B}\tilde{A}. \tag{1}$$

Let a, b, ... be constants. Identities include

$$[f(x), x] = 0 \tag{2}$$

$$[\tilde{A}, \tilde{A}] = 0 \tag{3}$$

$$[\tilde{A},\ \tilde{B}] = -[\tilde{B},\ \tilde{A}] \tag{4}$$

$$[\tilde{A},\ \tilde{B}\tilde{C}] = [\tilde{A},\ \tilde{B}]\tilde{C} + \tilde{B}[\tilde{A},\ \tilde{C}] \tag{5}$$

$$[\tilde{A}\tilde{B},\ \tilde{C}] = [\tilde{A},\ \tilde{C}]\tilde{B} + \tilde{A}[\tilde{B},\ \tilde{C}] \tag{6}$$

$$[a + \tilde{A},\ b + \tilde{B}] = [\tilde{A},\ \tilde{B}] \tag{7}$$

$$[\tilde{A} + \tilde{B},\ \tilde{C} + \tilde{D}] = [\tilde{A},\ \tilde{C}] + [\tilde{A},\ \tilde{D}] + [\tilde{B},\ \tilde{C}] + [\tilde{B},\ \tilde{D}]. \tag{8}$$

Let A and B be TENSORS. Then

$$[A,\ B] \equiv \nabla_A B - \nabla_B A. \tag{9}$$

There is a related notion of commutator in the theory of groups. The commutator of two GROUP elements A and B is $ABA^{-1}B^{-1}$, and two elements A and B are said to COMMUTE when their commutator is the IDENTITY ELEMENT. When the group is a LIE GROUP, the LIE BRACKET in its LIE ALGEBRA is an infinitesimal version of the group commutator. For instance, let A and B be square matrices, and let $\alpha(s)$ and $\beta(t)$ be paths in the LIE GROUP of INVERTIBLE MATRICES which satisfy

$$\alpha(0) = \beta(0) = 1 \tag{10}$$

$$\left.\frac{\partial x}{\partial s}\right|_{s=0} = \mathsf{A} \tag{11}$$

$$\left.\frac{\partial \beta}{\partial s}\right|_{s=0} = \mathsf{B}, \tag{12}$$

then

$$\frac{\partial}{\partial s}\frac{\partial}{\partial t}\ \alpha(s)\beta(t)\alpha^{-1}(s)\beta^{-1}(t)\Bigg|_{(s=0,\ t=0)} = 2[\mathsf{A},\ \mathsf{B}]. \tag{13}$$

Schafer, R. D. *An Introduction to Nonassociative Algebras.* New York: Dover, p. 13, 1996.

Commutator Series (Lie Algebra)

The commutator series of a LIE ALGEBRA $\mathfrak{g}$, sometimes called the derived series, is the sequence of subalgebras recursively defined by

$$\mathfrak{g}^{k+1} = [\mathfrak{g}^k,\ \mathfrak{g}^k],$$

with $\mathfrak{g}^0 = \mathfrak{g}$. The sequence of subspaces is always decreasing with respect to inclusion or dimension, and becomes stable when $\mathfrak{g}$ is finite dimensional. The notation $[\mathfrak{a},\ \mathfrak{b}]$ means the linear span of elements of the form $[A, B]$, where $A \in \mathfrak{a}$ and $B \in \mathfrak{b}$.

When the commutator series ends in the zero subspace, the Lie algebra is called SOLVABLE. For example, consider the LIE ALGEBRA of strictly UPPER TRIANGULAR MATRICES, then

$$\mathfrak{g}^0 = \begin{bmatrix} 0 & a_{12} & a_{13} & a_{14} & a_{15} \\ 0 & 0 & a_{23} & a_{24} & a_{25} \\ 0 & 0 & 0 & a_{34} & a_{35} \\ 0 & 0 & 0 & 0 & a_{45} \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix} \tag{1}$$

$$\mathfrak{g}^1 = \begin{bmatrix} 0 & 0 & a_{13} & a_{14} & a_{15} \\ 0 & 0 & 0 & a_{24} & a_{25} \\ 0 & 0 & 0 & 0 & a_{35} \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix} \tag{2}$$

$$\mathfrak{g}^2 = \begin{bmatrix} 0 & 0 & 0 & 0 & a_{15} \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix}, \tag{3}$$

and $\mathfrak{g}^3 = 0$. By definition, $\mathfrak{g}^k \subset \mathfrak{g}_k$ where $\mathfrak{g}_k$ is the term in the LOWER CENTRAL SERIES, as can be seen by the example above.

In contrast to the SOLVABLE LIE ALGEBRAS, the SEMISIMPLE LIE ALGEBRAS have a constant commutator series. Others are in between, e.g.,

$$[\mathfrak{gl}_n,\ \mathfrak{gl}_n] = \mathfrak{sl}_n, \tag{4}$$

which is semisimple, because the TRACE satisfies

$$\mathrm{Tr}(\mathsf{AB}) = \mathrm{Tr}(\mathsf{BA}). \tag{5}$$

Here, $\mathfrak{gl}_n$ is a general linear Lie algebra and $\mathfrak{sl}_n$ is the SPECIAL LINEAR LIE ALGEBRA.

Here are some *Mathematica* functions for determining the commutator series, given a list of matrices which is a basis for $\mathfrak{g}$.

```
MatrixBasis[a_List]:=
Partition[#1,Length[a[[1]]]]&/@
  LatticeReduce[Flatten/@a]
    LieCommutator[a_,b_]:=a.b-b.a
NextDerived[{}]={};
NextDerived[g_List]:=
MatrixBasis[Flatten[Outer[LieCommutator,g,g,1]
,1]]
kthDerived[g_List,k_Integer]:=
Nest[NextDerived,g,k]
```

For example,

```
gl5=Flatten[Table[ReplacePart
[Table

(Lie Algebra), Representation (Solvable Lie Group), Solvable Lie Group, Split Solvable Lie Algebra

Commutator Subgroup

The commutator subgroup of a group G is the subgroup generated by the commutators of its elements, and is denoted $[G, G]$. It is always a normal subgroup. It can range from the identity subgroup (in the case of an Abelian group), to the whole group. For instance, in the quaternion group $\{\pm 1, \pm i, \pm j, \pm k\}$ with eight elements, the commutators form the subgroup $\{1, -1\}$. The commutator subgroup of the symmetric group is the alternating group. The commutator subgroup of the alternating group A_n is the whole group A_n. When $n \geq 5$, A_n is a simple group and its only nontrivial normal subgroup is itself. Since $[A_n, A_n]$ is a nontrivial normal subgroup, it must be A_n.

The first homology of a group G is the Abelianization

$$H_1(G) = G/[G, G].$$

See also Abelian Group, Abelianization, Commutator, Group, Group Cohomology, Normal Subgroup

Commute

Two algebraic objects that are commutative, i.e., A and B such that $A * B = B * A$ for some operation $*$, are said to commute with each other.

See also Commutative, Commutator

Commuting Matrices

This entry contributed by Ronald M. Aarts

Two matrices A and B which satisfy

$$\mathsf{AB} = \mathsf{BA}$$

under matrix multiplication are said to be commuting.

In general, matrix multiplication is *not* commutative. Furthermore, in general there is no matrix inverse A^{-1} even when $\mathsf{A} \neq 0$. Finally, AB can be zero even without $\mathsf{A} = 0$ or $\mathsf{B} = 0$. And when $\mathsf{AB} = 0$, we may still have $\mathsf{BA} \neq 0$, a simple example of which is provided by

$$\mathsf{A} = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}$$

$$\mathsf{B} = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix},$$

for which

$$\mathsf{AB} = 0,$$

but

$$\mathsf{BA} = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} = \mathsf{A}$$

(Taussky 1957).

Co-Monotone Approximation

Comonotone Approximation

Comonotone Approximation

This entry contributed by Ronald M. Aarts

The approximation of a piecewise monotonic function f by a polynomial with the same monotonicity. Such comonotonic approximations can always be accomplished with nth degree polynomials, and have an error of $A\omega(f; 1/n)$ (Passow and Raymon 1974, Passow *et al.* 1974, Newman 1979).

Compact Closure

A set U has compact closure if its closure is compact. Typically, compact closure is equivalent to the condition that U is bounded.

See also Bounded, Compact Set, Topology

Compact Group

Compact Lie Group

Compact Lie Group

If the parameters of a Lie group vary over a closed interval, them the Lie group is said to be compact. Every representation of a compact group is equivalent to a unitary representation.

See also Lie Group

References

Huang, J.-S. "Compact Lie Groups." Part 3 in *Lectures on Representation Theory.* Singapore: World Scientific, pp. 71–28, 1999.

Compact Manifold

A compact manifold is a MANIFOLD which is compact as a TOPOLOGICAL SPACE. Examples are the CIRCLE (the only 1-D compact manifold) and the n-dimensional sphere and torus. Compact manifolds in two dimensions are completely classified by their orientation and the number of holes (GENUS).

For many problems in topology and geometry, it is convenient to study compact manifolds because of their "nice" behavior. Among the properties making compact manifolds "nice" are the fact that they can be covered by finitely many CHARTS, and that any continuous real-valued function is bounded on a compact manifold. However, it is an open question if the known compact manifolds in 3-D are complete, and it is not even known what a complete list in 4-D should look like. The following terse table therefore summarizes current knowledge about the number of compact manifolds $N(D)$ of D dimensions.

D	$N(D)$
1	1
2	2

See also MANIFOLD, SPHERE, TOPOLOGICAL SPACE, TORUS, TYCHONOF COMPACTNESS THEOREM

Compact Set

The SET S is compact if, from any SEQUENCE of elements X_1, X_2, ...of S, a subsequence can always be extracted which tends to some limit element X of S. Compact sets are therefore sets which are both CLOSED and BOUNDED.

See also BOUNDED SET, CLOSED SET

References

Croft, H. T.; Falconer, K. J.; and Guy, R. K. *Unsolved Problems in Geometry.* New York: Springer-Verlag, p. 2, 1991.

Compact Space

A TOPOLOGICAL SPACE is compact if every open cover of X has a finite subcover. In other words, if X is the union of a family of open sets, there is a finite subfamily whose union is X. A subset A of a TOPOLOGICAL SPACE X is compact if it is compact as a TOPOLOGICAL SPACE with the relative topology (i.e., every family of open sets of X whose union contains A has a finite subfamily whose union contains A).

Compact Support

A function has compact support if it is zero outside of a COMPACT SET. A function with compact support is only interesting in a BOUNDED domain. Alternatively, one can say that a function has compact support if its SUPPORT is a COMPACT SET. For example, the function $f: x \to x^2$ in its entire domain (i.e., $f: \mathbb{R} \to \mathbb{R}^+$) does not have compact support, while any BUMP FUNCTION does have compact support.

See also BUMP FUNCTION, COMPACT SET, SUPPORT

Compact Surface

A compact surface is a SURFACE which is also a COMPACT SET. A compact surface has a TRIANGULATION with a finite number of triangles. The SPHERE and TORUS are compact.

See also COMPACT SET, TRIANGULATION

Compactification

A compactification of a TOPOLOGICAL SPACE X is a larger space Y containing X which is also compact. The smallest compactification is the ONE-POINT COMPACTIFICATION. For example, the real line is not compact. It is contained in the circle, which is obtained by adding a point at infinity. Similarly, the plane is compactified by adding one point at infinity, giving the SPHERE.

See also COMPACT SET, STEREOGRAPHIC PROJECTION, TOPOLOGICAL SPACE

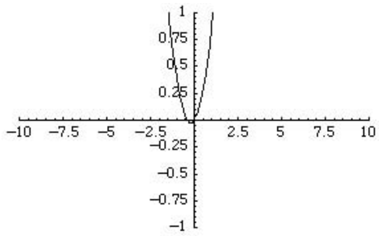
Compactness Theorem

Inside a BALL B in $\mathbb{R}^3$,

$$\{\text{rectifiable currents } S \text{ in } BL \text{ area } S \leq c, \text{ length } \partial S \leq c\}$$

is compact under the FLAT NORM.

References



Morgan, F. "What Is a Surface?" *Amer. Math. Monthly* **103**, 369–76, 1996.

Compact-Open Topology

The compact-open topology is a common topology used on FUNCTION SPACES. Suppose X and Y are TOPOLOGICAL SPACES and $C(X, Y)$ is the set of continuous maps from $f: X \to Y$. The compact-open topology on $C(X, Y)$ is generated by subsets of the following form,

$$B(K, U) = \{f | f(K) \subset U\},$$

where K is compact in X and U is open in Y. (Hence the terminology "compact-open.") It is important to note that these sets are not CLOSED under intersection, and do not form a BASIS. Instead, the sets $B(K, U)$ form a SUBBASIS for the compact-open topology. That is, the open sets in the compact-open topology are the arbitrary unions of finite intersections of $B(K, U)$.

The simplest FUNCTION SPACE to compare topologies is the space of real-valued continuous functions $f : \mathbb{R} \to \mathbb{R}$. A sequence of functions f_n converges to $f = 0$ IFF for every $B(K, U)$ containing f contains all but a finite number of the f_n. Hence, for all $K > 0$ and all $\epsilon > 0$, there exists an N such that for all $n > N$,

$$|f_n(x)| < \epsilon \quad \text{for all} \quad |x| \leq K.$$

For example, the sequence of functions $f_n = \sin(nx/2)/(n+1) + x^{2n}/e^{-n^2/2}$ converges to the zero function, although each function is unbounded.

When Y is a METRIC SPACE, the compact-open topology is the same as the topology of COMPACT CONVERGENCE. If X is a LOCALLY COMPACT HAUSDORFF space, a fairly weak condition, then the evaluation map

$$e : X \times C(X, Y) \to Y$$

defined by $e(x, f) = f(x)$ is CONTINUOUS. Similarly, $H : X \times Z \to Y$ is CONTINUOUS IFF the map $\tilde{H} : Z \to C(X, Y)$, given by $H(x, z) = \tilde{H}(z)(x)$, is CONTINUOUS. Hence, the compact-open topology is the right topology to use in HOMOTOPY theory.

Companion Knot

Let K_1 be a knot inside a TORUS. Now knot the TORUS in the shape of a second knot (called the companion knot) K_2. Then the new knot resulting from K_1 is called the SATELLITE KNOT K_3.

References

Adams, C. C. *The Knot Book: An Elementary Introduction to the Mathematical Theory of Knots.* New York: W. H. Freeman, pp. 115–18, 1994.

Companion Matrix

The companion matrix to a MONIC POLYNOMIAL

$$a(x) = a_0 + a_1 x + \ldots + a_{n-1} x^{n-1} + x^n \tag{1}$$

is the $n \times n$ SQUARE MATRIX

$$\mathsf{A} = \begin{bmatrix} 0 & 0 & \cdots & 0 & -a_0 \\ 1 & 0 & \cdots & 0 & -a_1 \\ 0 & 1 & \cdots & 0 & -a_2 \\ \vdots & \vdots & \ddots & \ddots & \vdots \\ 0 & 0 & \cdots & 1 & -a_{n-1} \end{bmatrix} \tag{2}$$

with ones on the SUBDIAGONAL and the last column given by the coefficients of $a(x)$. Note that in the literature, the companion matrix is sometimes defined with the rows and columns switched, i.e., the TRANSPOSE of the above matrix.

When e_i is the STANDARD BASIS, a companion matrix satisfies

$$\mathsf{A} e_i = e_{i+1} \tag{3}$$

for $i < n$, as well as

$$\mathsf{A} e_n = \sum -a_i e_i, \tag{4}$$

including

$$\mathsf{A}^n e_1 = \sum -a_i \mathsf{A}^i e_1. \tag{5}$$

The MINIMAL POLYNOMIAL of the companion matrix is therefore $a(x)$, which is also its CHARACTERISTIC POLYNOMIAL.

Companion matrices are used to write a matrix in RATIONAL CANONICAL FORM. In fact, any $n \times n$ matrix whose MINIMAL POLYNOMIAL $p(x)$ has DEGREE n is SIMILAR to the companion matrix for $p(x)$. The RATIONAL CANONICAL FORM is more interesting when the degree of $p(x)$ is less than n.

The following *Mathematica* command gives the companion matrix for a polynomial p in the variable x.

```
CompanionMatrix[p_,x_]:=
   Module[{rnk=Exponent[p,x],
      v=CoefficientList[p,x],w},
      w=Drop[v/Last[v],-1];
If[rnk==1,{-w},
Transpose[Append[(Prepend[#1,0]&/@IdentityMa-
trix[rnk-1]),-w]]]]
```

Compass

A tool with two arms joined at their ends which can be used to draw circles. In geometric constructions, the classical Greek rules stipulate that the compass cannot be used to mark off distances, so it must "collapse" whenever one of its arms is removed from the page. This results in significant complication in the complexity of geometric constructions.

Complement

In general, the word "complement" refers to that subset F' of some set S which excludes a given subset F. Taking F and its complement F' together then gives the whole of the original set. The notations F' and $\bar{F}$ are commonly used to denote the complement of a set F.

This concept is commonly used and made precise in the particular cases of a graph complement, knot complement, and complement set. The word "complementary" is also used in the same way, so combining an angle and its complementary angle gives a right angle and a complementary error function erfc and the usual error function erf give unity when added together,

$$\operatorname{erfc} x + \operatorname{erf} x = 1.$$

Complement Graph

Graph Complement

Complement Knot

Knot Complement

Complement Set

Given a set S with a subset E, the complement of E is defined as

$$E' \equiv \{F : F \in S,\ F \notin E\}. \qquad (1)$$

Using set difference notation, the complement is defined by

$$E' = S \backslash E. \qquad (2)$$

If $E = S$, then

$$E' \equiv S' = \varnothing, \qquad (3)$$

where $\varnothing$ is the empty set. The complement is implemented in *Mathematica* as `Complement[`l, $l1$, ...`]`.

Given a single set, the second probability axiom gives

$$1 = P(S) = P(E \cup E'). \qquad (4)$$

Using the fact that $E \cap E' = \varnothing$,

$$1 = P(E) + P(E') \qquad (5)$$

$$P(E') = 1 - P(E). \qquad (6)$$

This demonstrates that

$$P(S') = P(\varnothing) = 1 - P(S) = 1 - 1 = 0. \qquad (7)$$

Given two sets,

$$P(E \cap F') = P(E) - P(E \cap F) \qquad (8)$$

$$P(E' \cap F') = 1 - P(E) - P(F) + P(E \cap F). \qquad (9)$$

Complete Bipartite Graph

A BIPARTITE GRAPH (i.e., a set of VERTICES decomposed into two disjoint sets such that there are no two

VERTICES within the same set are adjacent) such that every pair of VERTICES in the two sets are adjacent. If there are p and q VERTICES in the two sets, the complete bipartite graph (sometimes also called a COMPLETE BIGRAPH) is denoted $K_{p,q}$. The above figures show $K_{3,2}$ and $K_{2,5}$. $K_{3,3}$ is also known as the UTILITY GRAPH, and is the unique 4-CAGE GRAPH.

A complete bipartite graph $K_{n,n}$ is a CIRCULANT GRAPH (Skiena 1990, p. 99). The complete bipartite graph $K_{18,18}$ illustrated above plays an important role in the novel by Eco (1989, p. 473; Skiena 1990, p. 143).

GAMMA FUNCTION, INCOMPLETE GAMMA FUNCTION

Complete Graph

A GRAPH in which each pair of VERTICES is connected by an EDGE. The complete graph with n VERTICES is denoted K_n, and has $\binom{n}{2}$ undirected edges, where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT. In older literature, complete GRAPHS are called UNIVERSAL GRAPHS.

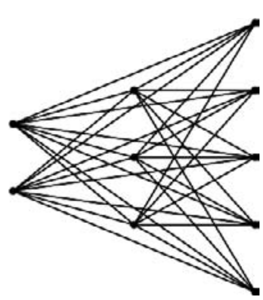
The number of EDGES in K_v is $v(v-1)/2$ (the triangular numbers), and the GENUS is $(v-3)(v-4)/12$ for $v \geq 3$. The ADJACENCY MATRIX A of the complete graph G takes the particularly simple form of all 1s with 0s on the diagonal, i.e., the UNIT MATRIX minus the IDENTITY MATRIX,

$$\mathsf{A} = \mathsf{J} - \mathsf{I}. \tag{1}$$

K_3 is the CYCLE GRAPH C_3, as well as the ODD GRAPH O_2 (Skiena 1990, p. 162). K_4 is the TETRAHEDRAL GRAPH, as well as the WHEEL GRAPH W_4, and is also a PLANAR GRAPH. K_5 is nonplanar. Conway and Gordon (1983) proved that every embedding of K_6 is INTRINSICALLY LINKED with at least one pair of linked

triangles. They also showed that any embedding of K_7 contains a knotted HAMILTONIAN CYCLE.

The CHROMATIC POLYNOMIAL $\pi K_n(z)$ of K_n is given by the FALLING FACTORIAL $(z)_n$, and the CHROMATIC NUMBER by n.



It is not known in general if a set of TREES with 1, 2, ..., $n-1$ EDGES can always be packed into K_n. However, if the choice of TREES is restricted to either the path or star from each family, then the packing can always be done (Zaks and Liu 1977, Honsberger 1985).

Complete Permutation

DERANGEMENT

Complete Product

The complete products of a BOOLEAN ALGEBRA of subsets generated by a set $\{A_k\}_{k=1}^p$ of CARDINALITY p are the 2^p BOOLEAN FUNCTIONS

$$B_1 B_2 \cdots B_p \equiv B_1 \cap B_2 \cap \cdots \cap B_p,$$

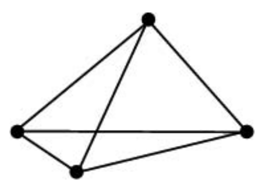
where each B_k may equal A_k or its complement $\bar{A}_k$. For example, the $2^3 = 8$ complete products of $A = \{A_1, A_2, A_3\}$ are

$$A_1A_2A_3,\ A_1A_2\bar{A}_3,\ A_1\bar{A}_2A_3,\ \bar{A}_1A_2A_3,$$

$$A_1\bar{A}_2\bar{A}_3,\ \bar{A}_1A_2\bar{A}_3,\ \bar{A}_1\bar{A}_2A_3,\ \bar{A}_1\bar{A}_2\bar{A}_3.$$

Each BOOLEAN FUNCTION has a unique representation (up to order) as a union of complete products. For example,

$$A_1A_2 \cup \bar{A}_3 = (A_1A_2A_3 \cup A_1A_2\bar{A}_3)$$
$$\cup (A_1A_2\bar{A}_3 \cup \bar{A}_1A_2\bar{A}_3 \cup A_1\bar{A}_2\bar{A}_3 \cup \bar{A}_1\bar{A}_2\bar{A}_3)$$
$$= A_1A_2A_3 \cup a_1A_2\bar{A}_3 \cup \bar{A}_1A_2\bar{A}_3 \cup A_1\bar{A}_2\bar{A}_3 \cup \bar{A}_1\bar{A}_2\bar{A}_3$$
$$= A_1A_2A_3 + A_1A_2\bar{A}_3 + \bar{A}_1\bar{A}_2\bar{A}_3$$



(Comtet 1974, p. 186).

Complete Quadrangle

If the four points making up a QUADRILATERAL are joined pairwise by six distinct lines, a figure known as a complete quadrangle results. A complete quadrangle is therefore a set of four points, no three collinear, and the six lines which join them. Note that a complete quadrilateral is different from a COMPLETE QUADRANGLE.

The midpoints of the sides of any complete quadrangle and the three diagonal points all lie on a CONIC known as the NINE-POINT CONIC. If it is an ORTHOCENTRIC QUADRILATERAL, the CONIC reduces to a CIRCLE. The ORTHOCENTERS of the four TRIANGLES of a complete quadrangle are COLLINEAR on the RADICAL LINE of the CIRCLES on the diameters of a QUADRILATERAL.

Complete Quadrilateral

The figure determined by four lines, no three of which are concurrent, and their six points of intersection (Johnson 1929, pp. 61–2). Note that this figure is different from a COMPLETE QUADRANGLE. A complete quadrilateral has three diagonals (compared to two for an ordinary QUADRILATERAL). The MIDPOINTS of the diagonals of a complete quadrilateral are COLLINEAR on a line M (Johnson 1929, pp. 152–53).

A theorem due to Steiner (Mention 1862, Johnson 1929, Steiner 1971) states that in a complete quadrilateral, the bisectors of angles are CONCURRENT at 16 points which are the incenters and EXCENTERS of the four TRIANGLES. Furthermore, these points are the intersections of two sets of four CIRCLES each of which is a member of a conjugate coaxal system. The axes of these systems intersect at the point common to the CIRCUMCIRCLES of the quadrilateral.

Newton proved that, if a CONIC SECTION is inscribed in a complete quadrilateral, then its center lies on M (Wells 1991). In addition, the ORTHOCENTERS of the four triangles formed by a complete quadrilateral lie on a line which is perpendicular to M. Plücker proved that the circles having the three diagonals as diameters have two common points which lie on the line joining the four triangles' ORTHOCENTERS (Wells 1991).

Complete Residue System

A set of numbers a_0, a_1, ..., a_{m-1} (mod m) form a complete set of residues, also called a covering system, if they satisfy

$$a_i \equiv i \pmod{m}$$

for $i = 0, 1, ..., m-1$. For example, a complete system of residues is formed by a base b and a modulus m if the residues r_i in $b^i \equiv r_i \pmod{m}$ for $i = 1, ..., m-1$ run through the values 1, 2, ..., $m-1$.

Complete Sequence

A sequence of numbers $V = \{v_n\}$ is complete if every positive integer n is the sum of some subsequence of V, i.e., there exist $a_i = 0$ or 1 such that

$$n = \sum_{i=1}^{\infty} a_i v_i$$

(Honsberger 1985, pp. 123–26). The Fibonacci numbers are complete. In fact, dropping one number still leaves a complete sequence, although dropping two numbers does not (Honsberger 1985, pp. 123 and 126). The sequence of primes with the element $\{1\}$ prepended,

$$\{1, 2, 3, 5, 7, 11, 13, 17, 19, 23, \ldots\}$$

is complete, even if any number of primes each > 7 are dropped, as long as the dropped terms do not include two consecutive primes (Honsberger 1985, pp. 127–28). This is a consequence of Bertrand's postulate.

Complete Set of Functions

A set of orthonormal functions $\{\phi_n(x)\}$ is termed complete in the closed interval $x \in [a, b]$ if, for every piecewise continuous function $f(x)$ in the interval, the minimum square error

$$E_n \equiv \|f - (c_1\phi_1 + \ldots + c_n\phi_n)\|^2$$

(where $\|f\|$ denotes the L2-norm with respect to a weighting function $w(x)$) converges to zero as n becomes infinite. Symbolically, a set of functions is complete if

$$\lim_{m\to\infty} \int_a^b \left[f(x) - \sum_{n=0}^{m} a_n \phi_n(x)\right]^2 w(x)\, dx = 0,$$

where the above integral is a Lebesgue integral.

Complete Tree

See also COMPLETE BINARY TREE, COMPLETE TERNARY TREE

Complete Vector Space

A VECTOR SPACE is complete if every CAUCHY SEQUENCE in the space converges to an element in the space. For example, the rationals are not complete, whereas the real numbers are.

See also VECTOR SPACE

Completely Monotonic Function

This entry contributed by RONALD M. AARTS

A completely monotonic function is a function $f(x)$ such that

$$(-1)^{-n} f^{(n)}(x) \geq 0$$

for $n = 0, 1, 2, ...$ Such functions occur in areas such as probability theory (Feller 1971), numerical analysis, and elasticity (Ismail *et al.* 1986).

See also COMPLETE CONVEX FUNCTION, MONOTONIC FUNCTION

Widder, D. V. *The Laplace Transform.* Princeton, NJ: Princeton University Press, 1941.

Completely Multiplicative Function

A real valued arithmetical function $f(n)$ is called completely multiplicative if

$$f(mn) = f(m) f(n)$$

holds for each pair of integers (m, n).

See also MULTIPLICATIVE FUNCTION

Completely Regular Graph

A POLYHEDRAL GRAPH is completely regular if the DUAL GRAPH is also REGULAR. There are only five types. Let ρ be the number of EDGES at each node, ρ^* the number of EDGES at each node of the DUAL GRAPH, V the number of VERTICES, E the number of EDGES, and F the number of faces in the PLATONIC SOLID corresponding to the given graph. The following table summarizes the completely regular graphs.

Type	ρ	ρ^*	V	E	F
Tetrahedral	3	3	4	6	4
Cubical	3	4	8	12	6
Dodecahedral	3	5	20	39	12
Octahedral	4	3	6	12	8
Icosahedral	5	3	12	30	20

Completeness Property

All lengths can be expressed as REAL NUMBERS.

Completing the Square

The conversion of an equation OF THE FORM $ax^2 + bx + c$ to the form

$$a\left(x + \frac{b}{2a}\right)^2 + \left(c - \frac{b^2}{4a}\right),$$

which, defining $B \equiv b/2a$ and $C \equiv c - b^2/4a$, simplifies to

$$a(x+B)^2 + C.$$

Completion

A METRIC SPACE X which is not complete has a CAUCHY SEQUENCE which does not CONVERGE. The completion of X is obtained by adding the limits to the Cauchy sequences. The completion is always COMPLETE.

For example, the rational numbers, with the distance metric, are not complete because there exist CAUCHY SEQUENCES that do not converge, e.g., 1, 1.4, 1.41, 1.414, ... does not converge because $\sqrt{2}$ is not rational. The completion of the rationals is the real numbers. Note that the completion depends on the METRIC. For instance, for any PRIME p, the rationals have a METRIC given by the P-ADIC NORM, and then the completion of the rationals is the set of P-ADIC NUMBERS. Another common example of a completion is the space of L2-FUNCTIONS.

Technically speaking, the completion of X is the set of CAUCHY SEQUENCES and X is contained in this set, ISOMETRICALLY, as the constant sequences.

Complex

CW-COMPLEX, SIMPLICIAL COMPLEX

Complex Addition

Two COMPLEX NUMBERS $z = x + iy$ and $z' = x' + iy'$ are added together componentwise,

$$z + z' = (x + x') + i(y + y').$$

In component form,

$$(x,\ y) + (x',\ y') = (x + x',\ y + y')$$

(Krantz 1999, p. 1).

Complex Analysis

The study of COMPLEX NUMBERS, their DERIVATIVES, manipulation, and other properties. Complex analysis is an extremely powerful tool with an unexpectedly large number of practical applications to the solution of physical problems. CONTOUR INTEGRATION, for example, provides a method of computing difficult INTEGRALS by investigating the singularities of the function in regions of the COMPLEX PLANE near and between the limits of integration.

The most fundamental result of complex analysis is the CAUCHY-RIEMANN EQUATIONS, which give the conditions a FUNCTION must satisfy in order for a complex generalization of the DERIVATIVE, the so-called COMPLEX DERIVATIVE, to exist. When the COMPLEX DERIVATIVE is defined "everywhere," the function is said to be ANALYTIC. A single example of the unexpected power of complex analysis is PICARD'S THEOREM, which states that an ANALYTIC FUNCTION assumes every COMPLEX NUMBER, with possibly one exception, infinitely often in any NEIGHBORHOOD of an ESSENTIAL SINGULARITY!

Complex Conjugate

The complex conjugate of a COMPLEX NUMBER $z \equiv a + bi$ is defined to be

$$\bar{z} \equiv a - bi. \qquad (1)$$

Note that there are several notations in common use for the complex conjugate. Older physics and engineering texts tend to prefer z^* (Bekefi and Barrett 1987, p. 616; Arfken 1985, p. 356; Harris and Stocker 1998, p. 21; Hecht 1998, p. 18; Herkommer 1999, p. 262), while many modern math and physics texts favor $\bar{z}$ (Abramowitz and Stegun 1972, p. 16; Kaplan 1981, p. 28; Roman 1987, p. 534; Kreyszig 1988, p. 568; Kaplan 1992, p. 572; Harris and Stocker 1998, p. 21; Krantz 1999, p. 2; Anton 2000, p. 528). In the latter case, the notation z^* is then reserved to denote the ADJOINT operator, which is denoted $z^\dagger$ in many older physics texts. In this work, $\bar{z}$ is used to denote the complex conjugate, and z^* is used to denote the ADJOINT.

The CONJUGATE MATRIX of a MATRIX $\mathsf{A} = (\mathsf{a}_{ij})$ is the MATRIX obtained by replacing each element a_{ij} with its complex conjugate, $\bar{\mathsf{A}} = (\bar{a}_{ij})$ (Arfken 1985, p. 210). The complex conjugate is implemented in *Mathematica* as `Conjugate[z]`.

The common notational conventions are summarized in the table below.

convention	complex conjugate	ADJOINT
mathematics	$\bar{\mathsf{A}}$	A^*

engineering	A*	A†

By definition, the complex conjugate satisfies

$$\bar{\bar{z}} = z. \tag{2}$$

The complex conjugate is distributive under complex addition,

$$\overline{z_1 + z_2} = \overline{z_1} + \overline{z_2}, \tag{3}$$

since

$$\begin{aligned}\overline{(a_1 + ib_1) + (a_2 + ib_2)} &= \overline{(a_1 + a_2) + i(b_1 + b_2)} \\ &= (a_1 + a_2) - i(b_1 + b_2) = (a_1 - ib_1) + (a_2 - ib_2) \\ &= \overline{a_1 + ib_1} + \overline{a_2 + ib_2},\end{aligned}$$

and distributive over complex multiplication,

$$\overline{z_1 z_2} = \bar{z}_1 \bar{z}_2, \tag{4}$$

since

$$\begin{aligned}\overline{(a_1 + b_1 i)(a_2 + b_2 i)} &= \overline{(a_1 a_2 - b_1 b_2) + i(a_1 b_2 + a_2 b_1)} \\ &= (a_1 a_2 - b_1 b_2) - i(a_1 b_2 + a_2 b_1) = (a_1 - ib_1)(a_2 - ib_2) \\ &= \overline{a_1 + ib_1 a_2 + ib_2}.\end{aligned}$$

Complex Derivative

A derivative of a complex function, which must satisfy the Cauchy-Riemann equations in order to be complex differentiable.

See also Cauchy-Riemann Equations, Complex Differentiable, Derivative

References

Krantz, S. G. "The Complex Derivative." §1.3.5 and 2.2.3 in *Handbook of Complex Analysis.* Boston, MA: Birkhäuser, pp. 15–6 and 24, 1999.

Complex Differentiable

Let $z = x + iy$ and $f(z) = u(x, y) + iv(x, y)$ on some region G containing the point z_0. If $f(z)$ satisfies the Cauchy-Riemann equations and has continuous first partial derivatives at z_0, then $f'(z_0)$ exists and is given by

$$f'(z_0) = \lim_{z \to z_0} \frac{f(z) - f(z_0)}{z - z_0},$$

and the function is said to be complex differentiable (or, equivalently, analytic, holomorphic, or regular).

A function $f : \mathbb{C} \to \mathbb{C}$ can be thought of as a map from the plane to the plane, $f : \mathbb{R}^2 \to \mathbb{R}^2$. Then f is complex differentiable iff its Jacobian is of the form

$$\begin{bmatrix} a & -b \\ b & a \end{bmatrix}$$

at every point. That is, its derivative is given by the multiplication of a complex number $a + bi$. For instance, the function $f(z) = \bar{z}$, where $\bar{z}$ is the complex conjugate, is *not* complex differentiable.

See also Analytic Function, Cauchy-Riemann Equations, Complex Derivative, Differentiable, Entire Function, Holomorphic Function, Pseudoanalytic Function

References

Krantz, S. G. "Alternative Terminology for Holomorphic Functions." §1.3.6 in *Handbook of Complex Analysis.* Boston, MA: Birkhäuser, p. 16, 1999.

Complex Division

The division of two complex numbers can be accomplished by multiplying the numerator and denominator by the complex conjugate of the denominator, for example, with $z_1 = a + bi$ and $z_2 = c + di$, $z = z_1/z_2$ is given by

$$\begin{aligned}z &= \frac{a + bi}{c + di} = \frac{(a + bi)\overline{c + di}}{(c + di)\overline{c + di}} = \frac{(a + bi)(c - di)}{(c + di)(c - di)} \\ &= \frac{(ac + bd) + i(bc - ad)}{c^2 + d^2},\end{aligned}$$

where $\bar{z}$ denotes the COMPLEX CONJUGATE. In component notation,

$$\frac{(x, y)}{(x', y')} = \left(\frac{xx' + yy'}{\sqrt{x'^2 + y'^2}}, \frac{yx' - xy'}{\sqrt{x'^2 + y'^2}} \right).$$

See also COMPLEX ADDITION, COMPLEX MULTIPLICATION, COMPLEX NUMBER, DIVISION

Complex Form (Type)

The DIFFERENTIAL FORMS on $\mathbb{C}^n$ decompose into forms of type (p, q). For example, on $\mathbb{C}$, the EXTERIOR ALGEBRA decomposes into four types:

$$\begin{aligned} \wedge \mathbb{C} &= \wedge^0 \oplus \wedge^{1,0} \oplus \wedge^{0,1} \oplus \wedge^{1,1} \\ &= \langle 1 \rangle \oplus \langle dz \rangle \oplus \langle d\bar{z} \rangle \oplus \langle dz \wedge d\bar{z} \rangle, \end{aligned} \qquad (1)$$

where $dz = dx + i\,dy$, $d\bar{z} = dx - i\,dy$, and $\otimes$ denotes the DIRECT SUM. In general, a (p, q)-form is the sum of terms with p dzs and q $d\bar{z}$s. A k-form decomposes into a sum of (p, q)-forms, where $k = p + q$.

For example, the 2-forms on $\mathbb{C}^2$ decompose as

$$\wedge^2 \mathbb{C}^2 = \wedge^{2,0} \oplus \wedge^{1,1} \oplus \wedge^{0,2} \qquad (2)$$

$$= \langle dz_1 \wedge dz_2 \rangle \oplus \langle dz_1 \wedge d\bar{z}_1, dz_1 \wedge d\bar{z}_2, dz_2 \wedge d\bar{z}_1, dz_2 \wedge d\bar{z}_2 \rangle \oplus \langle d\bar{z}_1 \wedge d\bar{z}_2 \rangle. \qquad (3)$$

The decomposition into forms of type (p, q) is preserved by HOLOMORPHIC MAPS. More precisely, when $f : X \to Y$ is holomorphic and α is a (p, q)-form on Y, then the PULLBACK $f^*\alpha$ is a (p, q)-form on X.

Recall that the EXTERIOR ALGEBRA is generated by the ONE-FORMS, by WEDGE PRODUCT and addition. Then the forms of type (p, q) are generated by

$$\Lambda^p(\Lambda^{1,\,0}) \wedge \Lambda^q(\Lambda^{0,\,1}). \qquad (4)$$

The SUBSPACE $\Lambda^{1,\,0}$ of the complex one-forms can be identified as the $+i$-EIGENSPACE of the ALMOST COMPLEX STRUCTURE J, which satisfies $J^2 = -I$. Similarly, the $-i$-EIGENSPACE is the SUBSPACE $\wedge^{0,\,1}$. In fact, the decomposition of $TX \otimes \mathbb{C} = TX^{1,\,0} \oplus TX^{0,\,1}$ determines the ALMOST COMPLEX STRUCTURE J on TX.

More abstractly, the forms into type (p, q) are a REPRESENTATION of $\mathbb{C}^*$, where λ acts by multiplication by $\lambda^p \bar{\lambda}^q$.

Complex Fraction

A FRACTION in which NUMERATOR and DENOMINATOR are themselves fractions.

See also COMMON FRACTION, FRACTION

Complex Function

A FUNCTION whose RANGE is in the COMPLEX NUMBERS is said to be a complex function, or a complex-valued function.

See also REAL FUNCTION, SCALAR FUNCTION, VECTOR FUNCTION

Complex Infinity

An infinite number in the COMPLEX PLANE whose ARGUMENT is unknown.

See also C*, DIVISION BY ZERO, EXTENDED COMPLEX PLANE, INFINITY, POINT AT INFINITY, RIEMANN SPHERE

Complex Line Integral

LINE INTEGRAL

Complex Manifold

A complex manifold is a MANIFOLD M whose COORDINATE CHARTS are open subsets of $\mathbb{C}^n$ and the TRANSITION FUNCTIONS between charts are HOLOMORPHIC FUNCTIONS. Naturally, a complex manifold of dimension n also has the structure of a REAL SMOOTH MANIFOLD of dimension $2n$.

A function $f : M \to \mathbb{C}$ is HOLOMORPHIC if it is HOLOMORPHIC in every COORDINATE CHART. Similarly, a map $f : M \to N$ is HOLOMORPHIC if its restrictions to coordinate charts on N are holomorphic. Two complex manifolds M and N are considered equivalent if there is a map $f : M \to N$ which is a DIFFEOMORPHISM and whose inverse is HOLOMORPHIC.

See also ALGEBRAIC VARIETY, CONFORMAL MAPPING, HOLOMORPHIC FUNCTION, MANIFOLD, RIEMANN SURFACE, STEIN MANIFOLD

Complex Matrix

A MATRIX whose elements may contain COMPLEX NUMBERS.

The MATRIX PRODUCT of two 2×2 complex matrices is given by

$$\begin{bmatrix} x_{11} + y_{11}i & x_{12} + y_{12}i \\ x_{21} + y_{21}i & x_{22} + y_{22}i \end{bmatrix} \begin{bmatrix} u_{11} + v_{11}i & u_{12} + v_{12}i \\ u_{21} + v_{21}i & u_{22} + v_{22}i \end{bmatrix}$$

$$= \begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} \end{bmatrix} + i \begin{bmatrix} I_{11} & I_{12} \\ I_{21} & I_{22} \end{bmatrix},$$

where

$$R_{11} = u_{11}x_{11} + u_{21}x_{21} - v_{11}y_{11} - v_{21}y_{12}$$

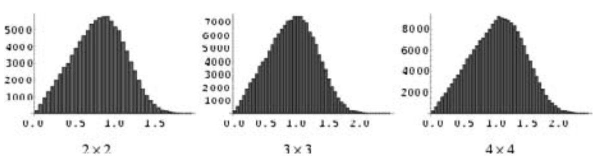
$$R_{12} = u_{12}x_{11} + u_{22}x_{12} - v_{11}y_{11} - v_{22}y_{12}$$

$$R_{21} = u_{11}x_{21} + u_{21}x_{22} - v_{11}y_{21} - v_{21}y_{22}$$

$$R_{22} = u_{12}x_{21} + u_{22}x_{22} - v_{12}y_{21} - v_{22}y_{22}$$

$$I_{11} = v_{11}x_{11} + v_{21}x_{21} + u_{11}y_{11} + u_{21}y_{12}$$

$$I_{12} = v_{12}x_{11} + v_{22}x_{12} + u_{12}y_{11} + u_{22}y_{12}$$



$$I_{21} = v_{11}x_{21} + u_{21}x_{22} + u_{11}y_{21} + u_{21}y_{22}$$

$$I_{22} = v_{12}x_{21} + v_{22}x_{22} + u_{12}y_{21} + u_{22}y_{22}.$$

Hadamard (1893) proved that the DETERMINANT of any complex $n \times n$ matrix A with entries in the closed UNIT DISK $|a_{ij}| \leq 1$ satisfies

$$|\det \mathsf{A}| \leq n^{n/2} \quad (1)$$

(HADAMARD'S MAXIMUM DETERMINANT PROBLEM), with equality attained by the VANDERMONDE MATRIX of the n ROOTS OF UNITY (Faddeev and Sominskii 1965, p. 331; Brenner 1972). The first few values for $n = 1, 2, \ldots$ are 1, 2, $3\sqrt{3}$, 16, $25\sqrt{5}$, 216, ...

Studying the maximum possible eigenvalue norms for random complex $n \times n$ matrices is computationally intractable. Although average properties of the distribution of $|\lambda|$ can be determined, finding the maximum value corresponds to determining if the set of matrices contains a SINGULAR MATRIX, which has been proven to be an NP-COMPLETE PROBLEM (Poljak and Rohn 1993, Kaltofen 1999). The above plots show the distributions for 2×2, 3×3, and 4×4 matrix eigenvalue norms for elements uniformly distributed inside the unit disk $|z| \leq 1$. Similar plots are obtained for elements uniformly distributed inside $|\Re[z]|, |\Im[z]| \leq 1$. The exact distribution of eigenvalues for complex matrices with both real and imaginary parts distributed as independent standard normal variates is given by Ginibre (1965), Hwang (1986), and Mehta (1991).

Complex Measure

A MEASURE which takes values in the COMPLEX NUMBERS. The set of complex measures on a MEASURE SPACE X forms a VECTOR SPACE. Note that this is not the case for the more common POSITIVE MEASURES. Also, the space of finite measures ($|\mu(X)| < \infty$) has a norm given by the TOTAL VARIATION MEASURE $\|\mu\| = |\mu|(X)|$, which makes it a BANACH SPACE.

Using the POLAR REPRESENTATION of μ, it is possible to define the LEBESGUE INTEGRAL using a complex measure,

$$\int f \, d\mu = \int e^{i\theta} f \, d|\mu|.$$

Sometimes, the term "complex measure" is used to indicate an arbitrary measure. The definitions for measure can be extended to measures which take values in any VECTOR SPACE. For instance in SPECTRAL THEORY, measures on $\mathbb{C}$, which take values in the bounded linear maps from a HILBERT SPACE to itself, represent the SPECTRUM of an operator.

Complex Modulus

MODULUS (COMPLEX NUMBER)

Complex Multiplication

Two COMPLEX NUMBERS $x = a + ib$ and $y = c + id$ are multiplied as follows:

$$xy = (a+ib)(c+id) = ac + ibc + iad - bd$$
$$= (ac - bd) + i(ad + bc).$$

In component form,

$$(x, y)(x', y') = (xx' - yy', xy' + yx') \quad (1)$$

(Krantz 1999, p. 1). The special case of a COMPLEX NUMBER multiplied by a SCALAR a is then given by

$$(x, y)(x', y') = (a, 0)(x, y) = (ax, ay). \quad (2)$$

Surprisingly, complex multiplication can be carried out using only three REAL multiplications, ac, bd, and $(a+b)(c+d)$ as

$$\Re[(a+ib)(c+id)] = ac - bd$$

$$\Im[(a+ib)(c+id)] = (a+b)(c+d) - ac - bd.$$

Complex multiplication has a special meaning for ELLIPTIC CURVES.

See also COMPLEX ADDITION, COMPLEX DIVISION, COMPLEX NUMBER, ELLIPTIC CURVE, IMAGINARY PART, MULTIPLICATION, REAL PART

Complex Number

The complex numbers are the FIELD $\mathbb{C}$ of numbers OF THE FORM $x+iy$, where x and y are REAL NUMBERS and I is the IMAGINARY UNIT equal to the SQUARE ROOT of -1, $\sqrt{-1}$. When a single letter $z = x+iy$ is used to denote a complex number, it is sometimes called an "AFFIX." In component notation, $z = x+iy$ can be written (x, y). The FIELD of complex numbers includes the FIELD of REAL NUMBERS as a SUBFIELD.

The set of complex numbers is implemented in *Mathematica* as `Complexes`. A number x can then be tested to see if it is complex using the command `Element[`x, Complexes].

Through the EULER FORMULA, a complex number

$$z = x + iy \quad (1)$$

may be written in "PHASOR" form

$$z = |z|(\cos\theta + i\sin\theta) = |z|e^{i\theta}. \quad (2)$$

Here, $|z|$ is known as the MODULUS and θ is known as the ARGUMENT or PHASE. The ABSOLUTE SQUARE of z is defined by $|z|^2 = z\bar{z}$, with $\bar{z}$ the COMPLEX CONJUGATE, and the argument may be computed from

$$\arg(z) = \theta = \tan^{-1}\left(\frac{y}{x}\right). \quad (3)$$

DE MOIVRE'S IDENTITY relates POWERS of complex numbers

$$z^n = |z|^n[\cos(n\theta) + i\sin(n\theta)]. \quad (4)$$

COMPLEX DIVISION and COMPLEX MULTIPLICATION can also be defined for complex numbers.

Finally, the REAL $\Re(z)$ and IMAGINARY PARTS $\Im(z)$ are given by

$$\Re(z) = \tfrac{1}{2}(z + \bar{z}) \quad (5)$$

$$\Im(z) = \frac{z - \bar{z}}{2i} = -\tfrac{1}{2}i(z - \bar{z}) = \tfrac{1}{2}i(\bar{z} - z). \quad (6)$$

The POWERS of complex numbers can be written in closed form as follows:

$$z^n = \left[x^n - \binom{n}{2}x^{n-2}y^2 + \binom{n}{4}x^{n-4}y^4 - \ldots\right]$$
$$+ i\left[\binom{n}{1}x^{n-1}y - \binom{n}{3}x^{n-3}y^3 + \ldots\right]. \quad (7)$$

The first few are explicitly

$$z^2 = (x^2 - y^2) + i(2xy) \quad (8)$$

$$z^3 = (x^3 - 3xy^2) + i(3x^2y - y) \quad (9)$$

$$z^4 = (x^4 - 6x^2y^2 + y^4) + i(4x^3y - 4xy^3) \quad (10)$$

$$z^5 = (x^5 - 10x^3y^2 + 5xy^4) + i(5x^4y - 10x^2y^3 + y^5) \quad (11)$$

(Abramowitz and Stegun 1972).

Complex Plane

The plane of COMPLEX NUMBERS spanned by the vectors 1 and i, where i is the IMAGINARY NUMBER. Every COMPLEX NUMBER corresponds to a unique POINT in the complex plane. The LINE in the plane with $i = 0$ is the REAL LINE. The complex plane is sometimes called the ARGAND PLANE or GAUSS PLANE, and a plot of COMPLEX NUMBERS in the plane is sometimes called an ARGAND DIAGRAM.

Complex Projective Plane

The set $\mathbb{P}^2$ is the set of all EQUIVALENCE CLASSES $[a, b, c]$ of ordered triples $(a, b, c) \in \mathbb{C}^3 \setminus (0, 0, 0)$ under the equivalence relation $(a, b, c) \sim (a', b', c')$ if $(a, b, c) = (\lambda a', \lambda b', \lambda c')$ for some NONZERO COMPLEX NUMBER λ.

See also COMPLEX PROJECTIVE PLANE

Complex Projective Space

See also COMPLEX SPACE, REAL PROJECTIVE SPACE

Complex Representation

PHASOR

Complex Space

See also COMPLEX PROJECTIVE SPACE, REAL SPACE, TWISTOR SPACE

Complex Structure

The complex structure of a point $\mathbf{x} = x_1, x_2$ in the PLANE is defined by the linear MAP $J : \mathbb{R}^2 \to \mathbb{R}^2$

$$J(x_1, x_2) = (-x_2, x_1),$$

and corresponds to a clockwise rotation by $\pi/2$. This map satisfies

$$J^2 = -I$$

$$(J\mathbf{x}) \cdot (J\mathbf{y}) = \mathbf{x} \cdot \mathbf{y}$$

$$(J\mathbf{x}) \cdot \mathbf{x} = 0,$$

where I is the IDENTITY MAP.

More generally, if V is a 2-D VECTOR SPACE, a linear map $J : V \to V$ such that $J^2 = -I$ is called a complex structure on V. If $V = \mathbb{R}^2$, this collapses to the previous definition.

Complex Vector

A VECTOR whose elements are COMPLEX NUMBERS.

See also COMPLEX NUMBER, REAL VECTOR, VECTOR

Complex Vector Bundle

A complex vector bundle is a VECTOR BUNDLE $\pi : E \to M$ whose FIBER $\pi^{-1}(x)$ is a COMPLEX VECTOR SPACE. It is not necessarily a COMPLEX MANIFOLD, even if its BASE MANIFOLD M is a COMPLEX MANIFOLD. If a complex vector bundle also has the structure of a COMPLEX MANIFOLD, and π is HOLOMORPHIC, then it is called a HOLOMORPHIC VECTOR BUNDLE.

See also Bundle, Complex Vector Space, Holomorphic Vector Bundle, Manifold, Vector Space

Complex Vector Space

A complex vector space is a vector space whose field of scalars is the complex numbers. A linear transformation between complex vector spaces is given by a matrix with complex entries (i.e., a complex matrix).

See also Basis (Vector Space), Complex Structure, Linear Transformation, Real Vector Space, Vector Space

Complexes

Complex Number

Complexity (Number)

The number of 1s needed to represent an integer using only additions, multiplications, and parentheses are called the integer's complexity. For example,

$$1 = 1$$

$$2 = 1 + 1$$

$$3 = 1 + 1 + 1$$

$$4 = (1 + 1)(1 + 1) = 1 + 1 + 1 + 1$$

$$5 = (1 + 1)(1 + 1) + 1 = 1 + 1 + 1 + 1 + 1$$

$$6 = (1 + 1)(1 + 1 + 1)$$

$$7 = (1 + 1)(1 + 1 + 1) + 1$$

$$8 = (1 + 1)(1 + 1)(1 + 1)$$

$$9 = (1 + 1 + 1)(1 + 1 + 1)$$

$$10 = (1 + 1 + 1)(1 + 1 + 1) + 1$$

$$= (1 + 1)(1 + 1 + 1 + 1 + 1)$$

So, for the first few n, the complexity is 1, 2, 3, 4, 5, 5, 6, 6, 6, 7, 8, 7, 8, ... (Sloane's A005245).

Complexity (Sequence)

Block Growth

Complexity Theory

The theory of classifying problems based on how difficult they are to solve. A problem is assigned to the P-problem (polynomial time) class if the number of steps needed to solve it is bounded by some power of the problem's size. A problem is assigned to the NP-problem (nondeterministic polynomial time) class if it permits a nondeterministic solution and the number of steps of the solution is bounded by some power of the problem's size. The class of P-problems is a subset of the class of NP-problems, but there also exist problems which are not np.

If a solution is known to an NP-problem, it can be reduced to a single period verification. A problem is NP-complete if an algorithm for solving it can be translated into one for solving any other NP-problem. Examples of NP-complete problems include the hamiltonian cycle and traveling salesman problems. Linear programming, thought to be an NP-problem, was shown to actually be a P-problem by L. Khachian in 1979. It is not known if all apparently NP-problems are actually P-problems.

Harary, F. *Graph Theory.* Reading, MA: Addison-Wesley, 1994.

Composite Knot

A KNOT which is not a PRIME KNOT. Composite knots are special cases of SATELLITE KNOTS.

See also KNOT, PRIME KNOT, SATELLITE KNOT

Composite Number

A composite number n is a POSITIVE INTEGER $n > 1$ which is not PRIME (i.e., which has FACTORS other than 1 and itself). The first few composite numbers (sometimes called "composites" for short) are 4, 6, 8, 9, 10, 12, 14, 15, 16, ... (Sloane's A002808), which can be written 2^2, $2 \cdot 3$, 2^3, 3^2, $2 \cdot 5$, $2^2 \cdot 3$, $2 \cdot 7$, $3 \cdot 5$, and 2^4, respectively. The number 1 is a special case which is considered to be neither composite nor PRIME.

A composite number C can always be written as a PRODUCT in at least two ways (since $1 \cdot C$ is always possible). Call these two products

$$C = ab = cd, \tag{1}$$

then it is obviously the case that $C|ab$ (C divides ab). Set

$$c = mn, \tag{2}$$

where m is the part of C which divides a, and n is the part of C which divides b. Then there are p and q such that

$$a = mp \tag{3}$$

$$b = nq. \tag{4}$$

Solving $ab = cd$ for d gives

$$d = \frac{ab}{c} = \frac{(mp)(nq)}{mn} = pq. \tag{5}$$

It then follows that

$$S \equiv a^2 + b^2 + c^2 + d^2 = m^2p^2 + n^2q^2 + m^2n^2 + p^2q^2$$
$$= (m^2 + q^2)(n^2 + p^2). \tag{6}$$

It therefore follows that $a^2 + b^2 + c^2 + d^2$ is never PRIME! In fact, the more general result that

$$S \equiv a^k + b^k + c^k + d^k \tag{7}$$

is never PRIME for k an INTEGER ≥ 0 also holds (Honsberger 1991).

Composite Runs

PRIME GAPS

Compositeness Certificate

A compositeness certificate is a piece of information which guarantees that a given number p is COMPOSITE. Possible certificates consist of a FACTOR of a number (which, in general, is much quicker to check by direct division than to determine initially), or of the determination that either

$$a^{p-1} \not\equiv 1 \pmod{p},$$

(i.e., p violates FERMAT'S LITTLE THEOREM), or

$$a \neq -1,\ 1 \text{ and } a^2 \equiv 1 \pmod{p}.$$

A quantity a satisfying either property is said to be a WITNESS to p's compositeness.

See also ADLEMAN-POMERANCE-RUMELY PRIMALITY TEST, FERMAT'S LITTLE THEOREM, MILLER'S PRIMALITY TEST, PRIMALITY CERTIFICATE, WITNESS

Compositeness Test

A test which always identifies PRIME NUMBERS correctly, but may incorrectly identify a COMPOSITE NUMBER as a PRIME.

See also PRIMALITY TEST

Composition

The combination of two FUNCTIONS to form a single new FUNCTION. The composition of two functions f and g is denoted $f \circ g$ and is defined by

$$f \circ g = f(g(x)), \tag{1}$$

where f is a function whose domain includes the range of g. The notation

$$f \circ g(x) = f(g(x)), \tag{2}$$

is sometimes used to explicitly indicate the symbol used for the variable.

Composition is associative, so that

$$f \circ (g \circ h) = (f \circ g) \circ h. \tag{3}$$

If the functions g is continuous at x_0 and f is continuous at $g(x_0)$, then $f \circ g$ is also continuous at x_0.

A combinatorial composition is defined as an unordered arrangement of k nonnegative integers which sum to n (Skiena 1990, p. 60). The compositions of n into k parts is given by Compositions[n, k] in the *Mathematica* add-on package DiscreteMath`Combinatorica` (which can be loaded with the command < <DiscreteMath`), and the number $C_k(n)$ of compositions of a number n of length k is given by the formula

$$C_k(n) = \binom{n+k-1}{k-1} = \frac{(n+k-1)!}{n!(k-1)!}, \tag{4}$$

implemented as NumberOfCompositions[n, k] in the *Mathematica* add-on package DiscreteMath`-Combinatorica` (which can be loaded with the command < <DiscreteMath`). The following table gives $C_k(n)$ for $n = 1, 2, \ldots$ and small k.

k	Sloane	$C_k(1)$, $C_k(2)$, ...

7	Sloane's A000579	7, 28, 84, 210, 462, 924, 1716, 3003, 5005, 8008, 12376, ...
8	Sloane's A000580	8, 36, 120, 330, 792, 1716, 3432, 6435, 11440, 19448, ...
9	Sloane's A000581	9, 45, 165, 495, 1287, 3003, 6435, 12870, 24310, 43758, ...

An operation called composition is also defined on BINARY QUADRATIC FORMS. For two numbers represented by two forms, the product can then be represented by the composition. For example, the composition OF THE FORMS $2x^2 + 15y^2$ and $3x^2 + 10y^2$ is given by $6x^2 + 5y^2$, and in this case, the product of 17 and 13 would be REPRESENTED AS ($(6 \cdot 36 + 5 \cdot 1 = 221)$). There are several algorithms for computing binary quadratic form composition, which is the basis for some factoring methods.

Composition Series

Every FINITE GROUP G of order greater than one possesses a finite series of SUBGROUPS, called a composition series, such that

$$I \lhd H_s \lhd \ldots \lhd H_2 \lhd H_1 \lhd G,$$

where H_{i+1} is a maximal subgroup of H_i and $H \lhd G$ means that H is a NORMAL SUBGROUP of G. A composition series is therefore a NORMAL SERIES without repetition whose factors are all simple (Scott 1987, p. 36).

The QUOTIENT GROUPS G/H_1, H_1/H_2, ..., H_{s-1}/H_s, H_s are called composition quotient groups.

Composition Theorem

Given a QUADRATIC FORM

$$Q(x, y) \equiv x^2 + y^2,$$

then

$$Q(x, y)Q(x', y') = Q(xx' - yy', x'y + x'y),$$

since

$$\begin{aligned}(x^2+y^2)(x'^2+y'^2) &= (xx'-yy')^2 + (xy'+x'y)^2 \\ &= x^2x'^2 + y^2y'^2 + x'^2y^2 + x^2y'^2.\end{aligned}$$

See also GENUS THEOREM, QUADRATIC FORM

Compound Interest

Let P be the PRINCIPAL (initial investment), r be the annual compounded rate, $i^{(n)}$ the "nominal rate," n be the number of times INTEREST is compounded per year (i.e., the year is divided into n CONVERSION PERIODS), and t be the number of years (the "term"). The INTEREST rate per CONVERSION PERIOD is then

$$r \equiv \frac{i^{(n)}}{n}. \tag{1}$$

If interest is compounded n times at an annual rate of r (where, for example, 10% corresponds to $r = 0.10$), then the effective rate over $1/n$ the time (what an investor would earn if he did not redeposit his interest after each compounding) is

$$(1+r)^{1/n}. \tag{2}$$

The total amount of holdings A after a time t when interest is re-invested is then

$$A = P\left(1 + \frac{i^{(n)}}{n}\right)^{nt} = P(1+r)^{nt}. \tag{3}$$

Note that even if interest is compounded continuously, the return is still finite since

$$\lim_{n\to\infty}\left(1+\frac{1}{n}\right)^n = e, \tag{4}$$

where E is the base of the NATURAL LOGARITHM.

The time required for a given PRINCIPAL to double (assuming $n = 1$ CONVERSION PERIOD) is given by solving

$$2P = P(1+r)^t, \tag{5}$$

or

$$t = \frac{\ln 2}{\ln(1+r)}, \tag{6}$$

where LN is the NATURAL LOGARITHM. This function can be approximated by the so-called RULE OF 72:

$$t \approx \frac{0.72}{r}. \tag{7}$$

POLYHEDRON COMPOUND

Compressible Surface

Let L be a LINK in $\mathbb{R}^3$ and let there be a DISK $\mathbb{D}$ in the LINK COMPLEMENT $\mathbb{R}^3 - L$. Then a surface F such that $\mathbb{D}$ intersects F exactly in its boundary and its boundary does not bound another disk on F is called a compressible surface (Adams 1994, p. 86).

Computability

COMPLEXITY THEORY

Computable Function

Any computable function can be incorporated into a PROGRAM using while-loops (i.e., "while something is true, do something else"). For-loops (which have a fixed iteration limit) are a special case of while-loops, so computable functions could also be coded using a combination of for- and while-loops. The ACKERMANN FUNCTION is the simplest example of a WELL DEFINED TOTAL FUNCTION which is computable but not PRIMITIVE RECURSIVE, providing a counterexample to the belief in the early 1900s that every computable function was also primitive recursive (Dötzel 1991).

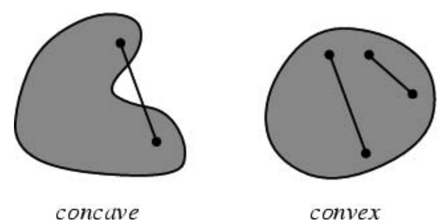
Concatenated Number Sequences
CONSECUTIVE NUMBER SEQUENCES

Concatenation
The concatenation of two strings a and b is the string ab formed by joining a and b. Thus the concatenation of the strings "book" and "case" is the string "bookcase". The concatenation of two strings a and b is often denoted ab, $a\|b$, or, in *Mathematica*, $a<>b$. Concatenation is an associative operation, so that the concatenation of three or more strings, for example abc, $abcd$, etc., is WELL DEFINED.

The concatenation of two or more numbers is the number formed by concatenating their numerals. For example, the concatenation of 1, 234, and 5678 is 12345678. The value of the result depends on the numeric base, which is typically understood from context.

The formula for the concatenation of numbers p and q in base b is

$$p\|q = pb^{l(q)} + q,$$

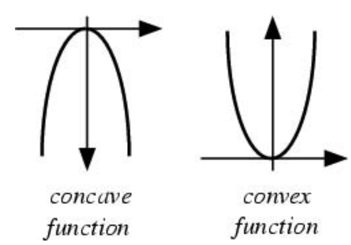


where

$$l(q) = \lfloor \log_b q \rfloor + 1$$

is the LENGTH of q in base b and $\lfloor x \rfloor$ is the FLOOR FUNCTION.

See also CONSECUTIVE NUMBER SEQUENCES, LENGTH (NUMBER), SMARANDACHE SEQUENCES



Concave

A SET in $\mathbb{R}^d$ is concave if it *does not* contain all the LINE SEGMENTS connecting any pair of its points. If the SET *does* contain all the LINE SEGMENTS, it is called CONVEX.

See also CONNECTED SET, CONVEX FUNCTION, CONVEX HULL, CONVEX OPTIMIZATION THEORY, CONVEX POLYGON, DELAUNAY TRIANGULATION, SIMPLY CONNECTED

Concave Function

A function $f(x)$ is said to be concave on an interval $[a, b]$ if, for any points x_1 and x_2 in $[a, b]$, the function $-f(x)$ is CONVEX on that interval (Gradshteyn and Ryzhik 2000).

See also CONVEX FUNCTION

Concentrated
Let μ be a POSITIVE MEASURE on a SIGMA ALGEBRA M, and let λ be an arbitrary (real or complex) MEASURE on M. If there is a SET $A \in M$ such that $\lambda(E) = \lambda(A \cap E)$ for every $E \in M$, then λ is said to be concentrated on A.

This is equivalent to requiring that $\lambda(E) = 0$ whenever $E \cap A = \emptyset$.

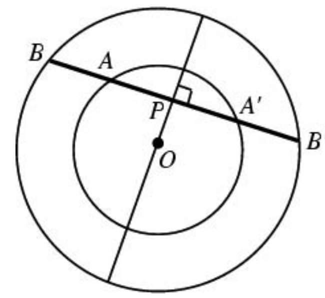
Concentric

Two geometric figures are said to be concentric if their centers coincide. The region between two concentric circles is called an annulus.

See also Annulus, Concentric Circles, Concyclic, Eccentric

Concentric Circles



Concentric circles are circles with a common center. The region between two concentric circles of different radii is called an annulus. Any two circles can be made concentric by inversion by picking the inversion center as one of the limiting points.

Given two concentric circles with radii R and $2R$, what is the probability that a chord chosen at random from the outer circle will cut across the inner circle? Depending on how the "random" chord is chosen, 1/2, 1/3, or 1/4 could all be correct answers.

1. Picking any two points on the outer circle and connecting them gives 1/3.
2. Picking any random point on a diagonal and then picking the chord that perpendicularly bisects it gives 1/2.
3. Picking any point on the large circle, drawing a line to the center, and then drawing the perpendicularly bisected chord gives 1/4.

So some care is obviously needed in specifying what is meant by "random" in this problem.

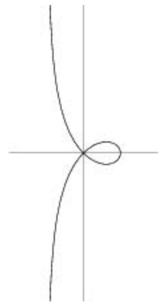
Given an arbitrary chord BB' to the larger of two concentric circles centered on O, the distance between inner and outer intersections is equal on both sides ($AB = A'B'$). To prove this, take the perpendicular to BB' passing through O and crossing at P. By symmetry, it must be true that PA and PA' are equal. Similarly, PB and PB' must be equal. Therefore, $PB - PA = AB$ equals $PB' - PA' = A'B'$. Incidentally, this is also true for homeoids, but the proof is nontrivial.

See also Annulus, Limiting Point

Conchoid

A curve whose name means "shell form." Let C be a curve and O a fixed point. Let P and P' be points on a line from O to C meeting it at Q, where $P'Q = QP = k$, with k a given constant. For example, if C is a circle and O is on C, then the conchoid is a limaçon, while in the special case that k is the diameter of C, then the conchoid is a cardioid. The equation for a parametrically represented curve $(f(t), g(t))$ with $O = (x_0, y_0)$ is

$$x = f \pm \frac{k(f - x_0)}{\sqrt{(f - x_0)^2 + (g - y_0)^2}}$$



$$y = g \pm \frac{k(g - y_0)}{\sqrt{(f - x_0)^2 + (g - y_0)^2}}.$$

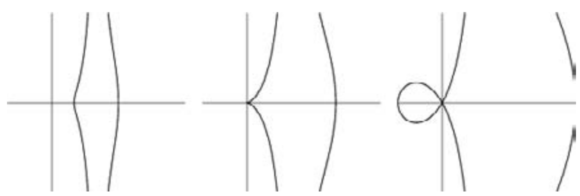
Conchoid of de Sluze

A curve first constructed by René de Sluze in 1662. In CARTESIAN COORDINATES,



$$a(x-a)(x^2+y^2)=k^2x^2,$$

and in POLAR COORDINATES,

$$r=\frac{k^2\cos\theta}{a}+a\sec\theta.$$

The above curve has $k^2/a=1$, $a=-0.5$.

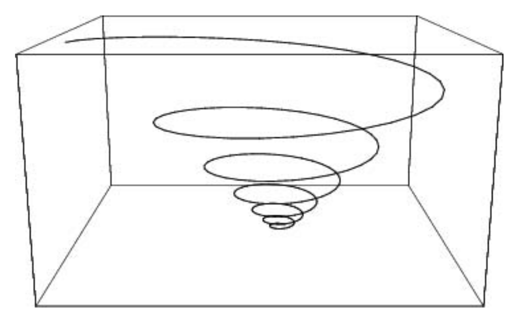
Conchoid of Nicomedes

A curve studied by the Greek mathematician Nicomedes in about 200 BC , also called the COCHLOID. It is the LOCUS of points a fixed distance away from a line as measured along a line from the FOCUS point (MacTutor Archive). Nicomedes recognized the three distinct forms seen in this family. This curve was a favorite with 17th century mathematicians and could be used to solve the problems of CUBE DUPLICATION, ANGLE TRISECTION, HEPTAGON construction, and other NEUSIS CONSTRUCTIONS (Johnson 1975).
In POLAR COORDINATES,

$$r=b+a\sec\theta. \tag{1}$$

In CARTESIAN COORDINATES,

$$(x-a)^2(x^2+y^2)=b^2x^2. \tag{2}$$



The conchoid has $x=a$ as an asymptote and the AREA between either branch and the ASYMPTOTE is infinite. The AREA of the loop is

$$A=a\sqrt{b^2-a^2}-2ab\ln\left(\frac{b+\sqrt{b^2-a^2}}{a}\right)+b^2\cos^{-1}\left(\frac{a}{b}\right). \tag{3}$$

Concho-Spiral

The SPACE CURVE with PARAMETRIC EQUATIONS

$$r=\mu^u a$$

$$\theta=u$$

$$z=\mu^u c.$$

See also CONICAL SPIRAL, SPIRAL

Concordant Form

A concordant form is an integer TRIPLE (a, b, N) where

$$\begin{cases} a^2 + b^2 = c^2 \\ a^2 + Nb^2 = d^2, \end{cases}$$

with c and d integers. Examples include

$$\begin{cases} 14663^2 + 111384^2 = 112345^2 \\ 14663^2 + 47 \cdot 111384^2 = 763751^2 \end{cases}$$

$$\begin{cases} 1141^2 + 13260^2 = 13309^2 \\ 1141^2 + 53 \cdot 13260^2 = 96541^2 \end{cases}$$

$$\begin{cases} 2873161^2 + 2401080^2 = 3744361^2 \\ 2873161^2 + 83 \cdot 2401080^2 = 22062761^2. \end{cases}$$

Dickson (1962) states that C. H. Brooks and S. Watson found in *The Ladies' and Gentlemen's Diary* (1857) that $x^2 + y^2$ and $x^2 + Ny^2$ can be simultaneously squares for $N < 100$ only for 1, 7, 10, 11, 17, 20, 22, 23, 24, 27, 30, 31, 34, 41, 42, 45, 49, 50, 52, 57, 58, 59, 60, 61, 68, 71, 72, 74, 76, 77, 79, 82, 85, 86, 90, 92, 93, 94, 97, 99, and 100 (which evidently omits 47, 53, and 83 from above). The list of concordant primes less than 1000 is now complete with the possible exception of the 16 primes 103, 131, 191, 223, 271, 311, 431, 439, 443, 593, 607, 641, 743, 821, 929, and 971 (Brown).

Concur

Two or more lines which intersect in a POINT are said to concur.

See also CONCURRENT

References

Coxeter, H. S. M. and Greitzer, S. L. "Collinearity and Concurrence." Ch. 3 in *Geometry Revisited.* Washington, DC: Math. Assoc. Amer., pp. 51–9, 1967.

Concurrency Principle

See also CONCURRENT RELATION

Concurrent

Two or more LINES are said to be concurrent if they intersect in a single point. Two LINES concur if their TRILINEAR COORDINATES satisfy

$$\begin{vmatrix} l_1 & m_1 & n_1 \\ l_2 & m_2 & n_2 \\ l_3 & m_3 & n_3 \end{vmatrix} = 0. \tag{1}$$

Three LINES concur if their TRILINEAR COORDINATES satisfy

$$l_1\alpha + m_1\beta + n_1\gamma = 0 \tag{2}$$

$$l_2\alpha + m_2\beta + n_2\gamma = 0 \tag{3}$$

$$l_3\alpha + m_3\beta + n_3\gamma = 0, \tag{4}$$

in which case the point is

$$m_2n_3 - n_2m_3 : n_2l_3 - l_2n_3 : l_2m_3 - m_2l_3. \tag{5}$$

Three lines

$$A_1x + B_1y + C_1 = 0 \tag{6}$$

$$A_2x + B_2y + C_2 = 0 \tag{7}$$

$$A_3x + B_3y + C_3 = 0 \tag{8}$$

are concurrent if their COEFFICIENTS satisfy

$$\begin{vmatrix} A_1 & B_1 & C_1 \\ A_2 & B_2 & C_2 \\ A_3 & B_3 & C_3 \end{vmatrix} = 0. \tag{9}$$

See also CONCYCLIC, POINT

Concurrent Normals Conjecture

It is conjectured that any convex body in Euclidean n-space has an interior lying on normals through $2n$ distinct boundary points (Croft *et al.* 1991). This has been proved for $n = 2$ and 3 by Heil (1979ab, 1985). It is known that higher dimensions always contain at least a 6-normal point, but the general conjecture remains open.

Concurrent Relation

Let X and Y be sets, and let $R \subseteq X \times Y$ be a relation on $X \times Y$. Then R is a concurrent relation if and only if for any finite subset F of X, there exists a single element p of Y such that if $a \in F$, then aRp. Examples of concurrent relations include the following:

1. The relation $<$ on either the natural numbers, the integers, the rational numbers, or the real numbers.
2. The relation R between elements of an extension $\mathbb{E}$ of a field $\mathbb{F}$, defined by

$$R = \{(a, b) \in \mathbb{E} \times \mathbb{E} : b \text{ is algebraic over } \mathbb{F} \text{ and } x \text{ is in the extension of } \mathbb{F} \text{ by } y\}.$$

3. The containment relation $\subseteq$ between open neighborhoods of a given point p of a TOPOLOGICAL SPACE X.

Concyclic

Four or more points P_1, P_2, P_3, P_4, ... which lie on a CIRCLE C are said to be concyclic. Three points are trivially concyclic since three noncollinear points determine a CIRCLE. The number of the n^2 LATTICE POINTS $x, y \in [1, n]$ which can be picked with no four concyclic is $\imath(n^{2/3} - \epsilon)$ (Guy 1994).

A theorem states that if any four consecutive points of a POLYGON are not concyclic, then its AREA can be increased by making them concyclic. This fact arises in some PROOFS that the solution to the ISOPERIMETRIC PROBLEM is the CIRCLE.

Condensation

A method of computing the DETERMINANT of a SQUARE MATRIX due to Charles Dodgson (1866) (who is more famous under his pseudonym Lewis Carroll). The method is useful for hand calculations because, for an INTEGER MATRIX, all entries in submatrices computed along the way must also be integers. The method is also implemented efficiently in a parallel computation. Condensation is also known as the method of contractants (Macmillan 1955, Lotkin 1959).

Given an $n \times n$ matrix, condensation successively computes an $(n-1) \times (n-1)$ matrix, an $(n-2) \times (n-2)$ matrix, etc., until arriving at a 1×1 matrix whose only entry ends up being the DETERMINANT of the original matrix. To compute the $k \times k$ matrix $(n-1 \geq k \geq 1)$, take the k^2 2×2 connected subdeterminants of the $(k+1) \times (k+1)$ matrix and divide them by the k^2 central entries of the $(k+2) \times (k+2)$ matrix, with no divisions performed for $k = n-1$. The $k \times k$ matrices arrived at in this manner are the matrices of determinants of the $k^2 (n-k+1) \times (n-k+1)$ connected submatrices of the original matrices.

For example, the first condensation of the 3×3 matrix

$$\begin{bmatrix} a & b & c \\ d & e & f \\ g & h & i \end{bmatrix}$$

yields the matrix

$$\begin{bmatrix} ae-bd & bf-ce \\ dh-eg & ei-fh \end{bmatrix},$$

and the second condensation yields

$$[((ae^2 i - aefh - bdei + bdfh) - (bdfh - befg - cdeh + ce^2 g))/e]$$

which is the determinant of the original matrix. Collecting terms gives

$$(1)aei + (-1)afh + (-1)bdi + (0)bde^{-1}fh + (1)bfg + (1)cdh + (-1)ceg,$$

of which the nonzero terms correspond to the PERMUTATION MATRICES. In the 4×4 case, 24 nonzero terms are obtained together with 18 vanishing ones. These 42 terms correspond to the ALTERNATING SIGN MATRICES for which any -1s in a row or column must have a +1 "outside" it (i.e., all -1s are "bordered" by +1s).

Condition

A requirement NECESSARY for a given statement or theorem to hold. Also called a CRITERION.

See also BOUNDARY CONDITIONS, CARMICHAEL CONDITION, CAUCHY BOUNDARY CONDITIONS, CONDITION NUMBER, DIRICHLET BOUNDARY CONDITIONS, DIVERSITY CONDITION, FELLER-LÉVY CONDITION, HÖLDER CONDITION, LICHNEROWICZ CONDITIONS, LINDEBERG CONDITION, LIPSCHITZ CONDITION, LYAPUNOV CONDITION, NEUMANN BOUNDARY CONDITIONS, ROBERTSON CONDITION, ROBIN BOUNDARY CONDITIONS, TAYLOR'S CONDITION, TRIANGLE CONDITION, WEIERSTRASS-ERDMAN CORNER CONDITION, WINKLER CONDITIONS

Condition Number

The ratio of the largest to smallest SINGULAR VALUE of a MATRIX. A system is said to be SINGULAR if the condition number is INFINITE, and ILL-CONDITIONED if it is too large. The p-norm condition number of a matrix can be computed using `MatrixCondition-Number[m, p]` in the *Mathematica* add-on package `LinearAlgebra`MatrixMultiplication`` (which can be loaded with the command `<<LinearAlgebra``) for $p = 1, 2$, or ∞, where omitting the p is equivalent to specifying `Infinity`.

See also ILL-CONDITIONED MATRIX, SINGULAR MATRIX, SINGULAR VALUE DECOMPOSITION

Conditional

The formal term in PROPOSITIONAL CALCULUS for the CONNECTIVE IMPLIES.

See also BICONDITIONAL, IMPLIES

References

Mendelson, E. *Introduction to Mathematical Logic, 4th ed.* London: Chapman & Hall, p. 13, 1997.

Conditional Convergence

If the SERIES

$$\sum_{n=0}^{\infty} u_n$$

CONVERGES, but

$$\sum_{n=0}^{\infty} |u_n|$$

does not, where $|x|$ is the ABSOLUTE VALUE, then the SERIES is said to be conditionally CONVERGENT. The RIEMANN SERIES THEOREM states that, by a suitable rearrangement of terms, a conditionally convergent SERIES may be made to converge to any desired value, or to DIVERGE.

See also ABSOLUTE CONVERGENCE, CONVERGENCE TESTS, DIVERGENT SERIES, RIEMANN SERIES THEOREM, SERIES

Conditional Probability

The conditional probability of an EVENT A assuming that B has occurred, denoted $P(A|B)$, equals

$$P(A|B) = \frac{P(A \cap B)}{P(B)}, \tag{1}$$

which can be proven directly using a VENN DIAGRAM. Multiplying through, this becomes

$$P(A|B)P(B) = P(A \cap B), \tag{2}$$

which can be generalized to

$$P(A \cap B \cap C) = P(A)P(B|A)P(C|A \cap B). \tag{3}$$

Rearranging (1) gives

$$P(B|A) = \frac{P(B \cap A)}{P(A)}. \tag{4}$$

Solving (4) for $P(B \cap A) = P(A \cap B)$ and plugging in to (1) gives

$$P(A|B) = \frac{P(A)P(B|A)}{P(B)}. \tag{5}$$

Condom Problem

GLOVE PROBLEM

Condon-Shortley Phase

The $(-1)^m$ phase factor in some definitions (e.g., Arfken 1985) of the SPHERICAL HARMONICS and associated LEGENDRE POLYNOMIALS. Using the Condon-Shortley convention gives

$$Y_l^m(\theta, \phi) = (-1)^m \sqrt{\frac{2l+1}{4\pi} \frac{(l-m)!}{(l+m)!}} P_l^m(\cos\theta) e^{im\phi}.$$

The Condon-Shortley phase is not necessary in the definition of the SPHERICAL HARMONICS, but including it simplifies the treatment of angular moment in quantum mechanics. In particular, they are a consequence of the ladder operators L_- and L_+ (Arfken 1985, p. 693).

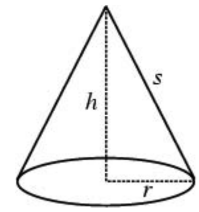
Conductor



J-CONDUCTOR

Cone

A cone is a PYRAMID with a circular CROSS SECTION, and a right cone is a cone with its vertex above the center of its base. However, in discussions of CONIC SECTIONS, the word "cone" is taken mean "DOUBLE CONE," consisting of two cones placed apex to apex. This is a QUADRATIC SURFACE, and each single cone is called a "NAPPE." The HYPERBOLA can then be defined as the intersection of a PLANE with both NAPPES of the cone.

A right cone of height h can be described by the PARAMETRIC EQUATIONS

$$x = \frac{h-z}{h} r \cos\theta \tag{1}$$

$$y = \frac{h-z}{h} r \sin\theta \tag{2}$$

$$z = z \tag{3}$$

for $z \in [0, h]$ and $\theta \in [0, 2\pi)$. The VOLUME of a cone is therefore

$$V = \tfrac{1}{3} A_b h, \tag{4}$$

where A_b is the base AREA and h is the height. If the base is circular, then

$$V = \tfrac{1}{3} \pi r^2 h. \tag{5}$$

This amazing fact was first discovered by Eudoxus, and other proofs were subsequently found by Archimedes in *On the Sphere and Cylinder* (ca. 225 BC) and Euclid in Proposition XII.10 of his *ELEMENTS* (Dunham 1990).

The CENTROID can be obtained by setting $R_2 = 0$ in the equation for the centroid of the CONICAL FRUSTUM,

$$\bar{z} = \frac{\langle z \rangle}{V} = \frac{h(R_1^2 + 2R_1R_2 + 3R_2^2)}{4(R_1^2 + R_1R_2 + R_2^2)}, \tag{6}$$

(Eshbach 1975, p. 453; Beyer 1987, p. 133) yielding

$$\bar{z} = \tfrac{1}{4} h. \tag{7}$$

For a right circular cone, the SLANT HEIGHT s is

$$s = \sqrt{r^2 + h^2} \tag{8}$$

and the surface AREA (not including the base) is

$$S = \pi r s = \pi r \sqrt{r^2 + h^2}. \tag{9}$$

The LOCUS of the apex of a variable cone containing an ELLIPSE fixed in 3-space is a HYPERBOLA through the FOCI of the ELLIPSE. In addition, the LOCUS of the apex of a cone containing that HYPERBOLA is the original ELLIPSE. Furthermore, the ECCENTRICITIES of the ELLIPSE and HYPERBOLA are reciprocals.

There are three ways in which a grid can be mapped onto a cone so that it forms a CONE NET (Steinhaus 1983, pp. 225–27).

Using the parameterization

$$x = \frac{h - u}{h} r \cos v \quad (10)$$

$$y = \frac{h - u}{h} r \sin v \quad (11)$$

$$z = u \quad (12)$$

gives coefficients of the FIRST FUNDAMENTAL FORM

$$E = 1 + \frac{r^2}{h^2} \quad (13)$$

$$F = 0 \quad (14)$$

$$G = \frac{r^2(h - u)^2}{h^2}, \quad (15)$$

SECOND FUNDAMENTAL FORM coefficients

$$e = 0 \quad (16)$$

$$f = 0 \quad (17)$$

$$g = \frac{r(h - u)}{\sqrt{h^2 + r^2}}, \quad (18)$$

AREA ELEMENT

$$dS = \frac{r\sqrt{h^2 + r^2}}{h^2}(h - u), \quad (19)$$

GAUSSIAN CURVATURE

$$K = 0, \quad (20)$$

and MEAN CURVATURE

$$M = \frac{h^2}{\sqrt{h^2 + r^2}(2hr - 2ru)}. \quad (21)$$

Note that writing $z = v$ instead of $z = u$ would give a HELICOID instead of a CONE.

Cone Graph

A GRAPH $C_n + \overline{K_m}$, where C_n is a CYCLIC GRAPH and K_m is a COMPLETE GRAPH.

Cone Net

The mapping of a grid of regularly ruled squares onto a CONE with no overlap or misalignment. Cone nets are possible for vertex angles of 90°, 180°, and 270°, where the dark edges in the upper diagrams above are joined. Beautiful photographs of cone net models (lower diagrams above) are presented in Steinhaus (1983). The transformation from a point (x, y) in the

grid plane to a point (x', y', z') on the cone is given by

$$x' = rn \cos\left(\frac{\theta}{n}\right) \quad (1)$$

$$y' = rn \sin\left(\frac{\theta}{n}\right) \quad (2)$$

$$z' = (1-r)h, \quad (3)$$

where $n = 1/4$, $1/2$, or $3/4$ is the fraction of a circle forming the base, and

$$h = \sqrt{1-n^2} \quad (4)$$

$$\theta = \tan^{-1}\left(\frac{y}{x}\right) \quad (5)$$

$$r = \sqrt{x^2+y^2}. \quad (6)$$

Cone-Plane Intersection

CONIC SECTION

Cone-Sphere Intersection

Let a CONE of opening parameter c and vertex at $(0, 0, 0)$ intersect a SPHERE of RADIUS r centered at (x_0, y_0, z_0), with the CONE oriented such that its axis does not pass through the center of the SPHERE. Then the equations of the curve of intersection are

$$\frac{x^2+y^2}{c^2} = z^2 \quad (1)$$

$$(x-x_0)^2 + (y-y_0)^2 + (z-z_0)^2 = r^2. \quad (2)$$

Combining (1) and (2) gives

$$(x-x_0)^2 + (y-y_0)^2 + \frac{x^2+y^2}{c^2} - \frac{2z_0}{c}\sqrt{x^2+y^2} + z_0^2 = r^2 \quad (3)$$

$$x^2\left(1+\frac{1}{c^2}\right) - 2x_0x + y^2\left(1+\frac{1}{c^2}\right) - 2y_0y + (x_0^2+y_0^2+z_0^2-r^2) - \frac{2z_0}{c}\sqrt{x^2+y^2} = 0. \quad (4)$$

Therefore, x and y are connected by a complicated QUARTIC EQUATION, and x, y, and z by a QUADRATIC EQUATION.

If the CONE-SPHERE intersection is *on-axis* so that a CONE of opening parameter c and vertex at $(0, 0, z_0)$ is oriented with its AXIS along a radial of the SPHERE of radius r centered at $(0, 0, 0)$, then the equations of the curve of intersection are

$$(z-z_0)^2 = \frac{x^2+y^2}{c^2} \quad (5)$$

$$x^2+y^2+z^2 = r^2. \quad (6)$$

Combining (5) and (6) gives

$$c^2(z-z_0)^2 + z^2 = r^2 \quad (7)$$

$$c^2(z^2 - 2z_0z + z_0^2) + z^2 = r^2 \quad (8)$$

$$z^2(c^2+1) - 2c^2z_0z + (z_0^2c^2 - r^2) = 0. \quad (9)$$

Using the QUADRATIC EQUATION gives

$$z = \frac{2c^2z_0 \pm \sqrt{4c^4z_0^2 - 4(c^2+1)(z_0^2c^2-r^2)}}{2(c^2+1)}$$

$$= \frac{c^2z_0 \pm \sqrt{c^2(r^2-z_0^2)+r^2}}{c^2+1}. \quad (10)$$

So the curve of intersection is planar. Plugging (10) into (5) shows that the curve is actually a CIRCLE, with RADIUS given by

$$a = \sqrt{r^2-z^2}. \quad (11)$$

Confidence Interval

The probability that a measurement will fall within a given CLOSED INTERVAL $[a, b]$. For a CONTINUOUS DISTRIBUTION,

$$\mathrm{CI}(a, b) \equiv \int_b^a P(x)\,dx, \quad (1)$$

where $P(x)$ is the PROBABILITY DISTRIBUTION FUNCTION. Usually, the confidence interval of interest is symmetrically placed around the mean, so

$$\mathrm{CI}(x) \equiv \mathrm{CI}(\mu - x, \ \mu + x) = \int_{\mu-x}^{\mu+x} P(x)\, dx, \qquad (2)$$

where μ is the MEAN. For a GAUSSIAN DISTRIBUTION, the probability that a measurement falls within $n\sigma$ of the mean μ is

$$\mathrm{CI}(n\sigma) \equiv \frac{1}{\sigma\sqrt{2\pi}} \int_{\mu-n\sigma}^{\mu+n\sigma} e^{-(x-\mu)^2/2\sigma^2}\, dx$$
$$= \frac{2}{\sigma\sqrt{2\pi}} \int_0^{\mu+n\sigma} e^{-(x-\mu)^2/2\sigma^2}\, dx. \qquad (3)$$

Now let $u \equiv (x-\mu)/\sqrt{2}\sigma$, so $du = dx/\sqrt{2}\sigma$. Then

$$\mathrm{CI}(n\sigma) = \frac{2}{\sigma\sqrt{2\pi}} \sqrt{2}\sigma \int_0^{n/\sqrt{2}} e^{-u^2}\, du = \frac{2}{\sqrt{\pi}} \int_0^{n/\sqrt{2}} e^{-u^2}\, du$$
$$= \operatorname{erf}\left(\frac{n}{\sqrt{2}}\right) \qquad (4)$$

where erf(x) is the so-called ERF function. The variate value producing a confidence interval CI is often denoted x_{CI}, so

$$x_{\mathrm{CI}} = \sqrt{2}\, \operatorname{erf}^{-1}(\mathrm{CI}). \qquad (5)$$

range	CI
σ	0.6826895
2σ	0.9544997
3σ	0.9973002
4σ	0.9999366
5σ	0.9999994

To find the standard deviation range corresponding to a given confidence interval, solve (4) for n.

$$n = \sqrt{2}\operatorname{erf}^{-1}(\mathrm{CI}) \qquad (6)$$

CI	range
0.800	$\pm 1.28155\sigma$
0.900	$\pm 1.64485\sigma$
0.950	$\pm 1.95996\sigma$
0.990	$\pm 2.57583\sigma$
0.995	$\pm 2.80703\sigma$
0.999	$\pm 3.29053\sigma$

Configuration

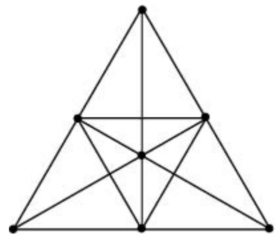
The word configuration is sometimes used to describe a finite collection of points $p = (p_1, \ldots, p_n)$, $p_i \in \mathbb{R}^d$, where $\mathbb{R}^d$ is a EUCLIDEAN SPACE.

The term "configuration" also is used to describe a finite incidence structure (v_r, b_k) with the following properties (Gropp 1992).

1. There are v points and b lines.
2. There are k points on each line and r lines through each point.
3. Two different lines intersect each other at most once and two different points are connected by a line at most once.

The conditions

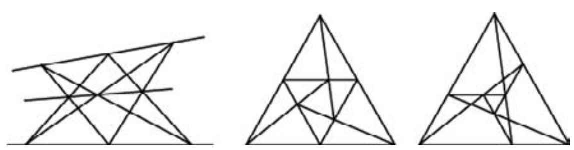
$$vr = bk$$



$$v \geq r(k-1) + 1$$

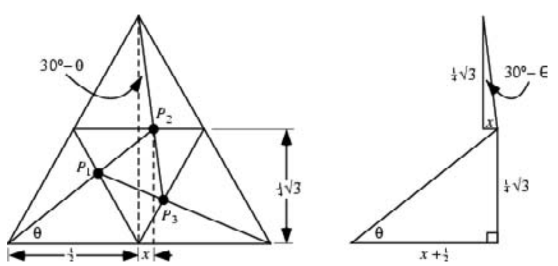
are NECESSARY for the existence of a configuration. For $k = 3$, these conditions are also SUFFICIENT, and for $k = 4$ this is probably also the case (Gropp 1992). The necessary conditions hold, but there is no 22_5. For $k = 6$ and 7, the above conditions are not SUFFICIENT, as illustrated by the affine projective plane of order 6 $(36_7, 42_6)$ and the projective plane $(43_7, 43_7)$.

Configurations are among the oldest combinatorial structures, having been defined by T. Reye in 1876. An r-REGULAR GRAPH can be regarded as a configuration (v_r, b_2) by associating nodes with the points, and edges with the lines. The following table summarizes the number of different configurations for some special values (Gropp 1992).



configuration	distinct
$(12_2, 8_3)$	5
$(15_2, 10_3)$	18

A symmetric configuration $n_k = (n_k, n_k)$ consists of n lines and n points arranged such that k lines pass through each point and there are k points on each line. All symmetric n_3 configurations are known for $n \leq 14$. The number of 7_3, 8_3, $9_3 \ldots$ configurations are 1, 1, 3, 10, 31, 229, 2036, 21399, 245342, ..., correcting an error of von Sterneck for 12_3 (Sloane's A001403; Sterneck 1894, 1895; Wells 1991, p. 72; Colbourn and Dinitz 1996; Gropp 1997; Hilbert and Cohn-Vossen 1999).



The FANO PLANE, in which the central point corresponds to the POINT AT INFINITY, is the unique 7_3 configuration. There are no 7_3 configurations using points all at finite distances (Wells 1986, p. 75).

There are no 8_3 configurations using points all at finite distances (Wells 1986, p. 75), but a single configuration exists with a POINT AT INFINITY.

There are three 9_3 configurations, of which PAPPUS'S HEXAGON THEOREM (left figure) is one (Wells 1985, p. 75). The other two consist of embedded EQUILATERAL TRIANGLES (Wells 1991, pp. 159–60).

In the second 9_3 configuration, the angle θ can be computed using the above figure. For the top triangle, trigonometry gives

$$\tan(30^\circ - \theta) = \frac{x}{\frac{1}{4}\sqrt{3}}. \tag{1}$$

Solving for x and plugging into the trigonometric equation from the bottom triangle gives

$$\tan\theta = \frac{\frac{1}{4}\sqrt{3}}{\frac{1}{2} + x} = \frac{\sqrt{3}}{2 + \sqrt{3}\tan(30^\circ - \theta)}. \tag{2}$$

Now using the identity

$$\tan(\alpha - \beta) = \frac{\tan\alpha - \tan\beta}{1 + \tan\alpha\tan\beta} \tag{3}$$

with $\alpha = \theta,\ \beta = 30^\circ$ gives

$$\tan(\theta - 30^\circ) = \frac{\tan\theta - \frac{1}{\sqrt{3}}}{1 + \frac{1}{\sqrt{3}}\tan\theta} = \frac{\sqrt{3}\tan\theta - 1}{\sqrt{3} + \tan\theta}. \tag{4}$$

Plugging in gives

$$\tan\theta\left(2 + \sqrt{3}\,\frac{\sqrt{3}\tan\theta - 1}{\sqrt{3} + \tan\theta}\right) = \sqrt{3}, \tag{5}$$

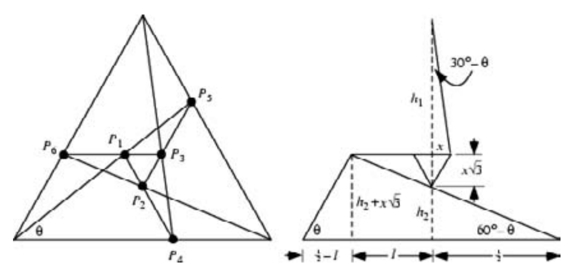
which simplifies to

$$\tan^2\theta = \sec^2\theta - 1 = \tfrac{3}{5} \tag{6}$$

$$\sec^2\theta = \tfrac{8}{5} \tag{7}$$

$$\cos^2\theta = \tfrac{1}{2}[1 + \cos(2\theta)] = \tfrac{5}{8} \tag{8}$$

$$\tfrac{1}{4} = \cos(2\theta) \tag{9}$$



$$\theta = \tfrac{1}{2}\cos^{-1}\left(\tfrac{1}{4}\right) \approx 0.659058 \text{ rad}. \tag{10}$$

Some additional trigonometry then gives the positions of the three innermost EQUILATERAL TRIANGLE vertices,

$$P_1 = \left(\tfrac{1}{8}(5 - \sqrt{5}),\ \tfrac{1}{8}(\sqrt{15} - \sqrt{3})\right) \tag{11}$$

$$P_2 = \left(\tfrac{1}{4}\sqrt{5},\ \tfrac{1}{4}\sqrt{3}\right) \tag{12}$$

$$P_3 = \left(\tfrac{1}{8}(7 - \sqrt{5}),\ \tfrac{1}{8}(3\sqrt{3} - \sqrt{15})\right). \tag{13}$$

For the third 9_3 configuration, solving the five simultaneous equations

$$\tan(\theta - 30^\circ) = \frac{x}{h_1} \tag{14}$$

$$\tan(60^\circ - \theta) = \frac{h_2}{\frac{1}{2}} \tag{15}$$

$$h_1 + x\sqrt{3} + h_2 = \tfrac{1}{2}\sqrt{3} \tag{16}$$

$$\tan(60^\circ - \theta) = \frac{\sqrt{3} - \tan\theta}{1 + \sqrt{3}\tan\theta} = \frac{h_2 + x\sqrt{3}}{l + \frac{1}{2}} \tag{17}$$

$$\tan 60^\circ = \sqrt{3} = \frac{h_2 + x\sqrt{3}}{\frac{1}{2} - l} \tag{18}$$

gives

$$\theta = \tfrac{1}{2}\cos^{-1}\left(\tfrac{1}{4}\right) \quad (19)$$

$$x = \tfrac{1}{4}(7 - 3\sqrt{5}) \quad (20)$$

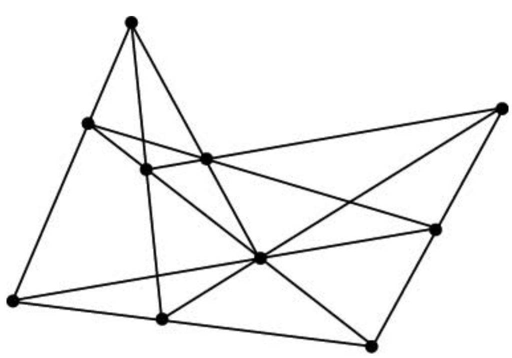
$$l = \tfrac{1}{4}(\sqrt{5} - 1) \quad (21)$$

$$h_1 = \tfrac{1}{4}(\sqrt{15} - \sqrt{3}) \quad (22)$$

$$h_2 = \tfrac{1}{2}(\sqrt{15} - 2\sqrt{3}). \quad (23)$$

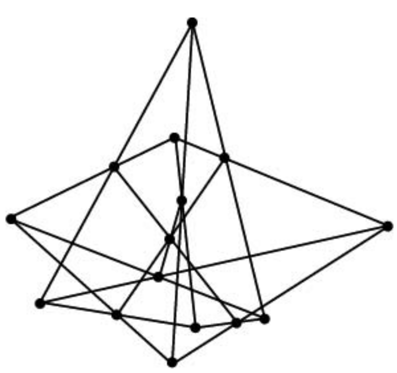
The six points are then given by

$$P_1 = \left(\tfrac{1}{4}(3\sqrt{5} - 5),\ \tfrac{1}{4}(3\sqrt{3} - \sqrt{15})\right) \quad (24)$$



$$P_2 = \left(\tfrac{1}{2},\ \tfrac{1}{2}(\sqrt{15} - 2\sqrt{3})\right) \quad (25)$$

$$P_3 = \left(\tfrac{3}{4}(3 - \sqrt{5}),\ \tfrac{1}{4}(3\sqrt{3} - \sqrt{15})\right) \quad (26)$$



$$P_4 = \left(\tfrac{1}{2}(\sqrt{5} - 1),\ 0\right) \quad (27)$$

$$P_5 = \left(\tfrac{1}{4}(5 - \sqrt{5}),\ \tfrac{1}{4}(\sqrt{15} - \sqrt{3})\right) \quad (28)$$

$$P_6 = \left(\tfrac{1}{4}(3 - \sqrt{5}),\ \tfrac{1}{4}(3\sqrt{3} - \sqrt{15})\right). \quad (29)$$

The DESARGUES CONFIGURATION, illustrated above, is one of the ten 10_3 configurations. Page and Dorwart (1984) discuss the 31 11_3 configurations (Wells 1991, p. 63).

The CREMONA-RICHMOND CONFIGURATION, illustrated above, is one of the 245342 15_3 configurations.

Confluent Hypergeometric Differential Equation

The second-order ordinary differential equation

$$xy'' + (c - x)y' - ay = 0, \quad (1)$$

sometimes also called Kummer's differential equation (Zwillinger 1997, p. 124). It has a REGULAR SINGULAR POINT at 0 and an irregular singularity at ∞. The solutions

$$y = b_1\,{}_1F_1(a;\ c;\ x) + b_2 U(a,\ c,\ x) \quad (2)$$

are called CONFLUENT HYPERGEOMETRIC FUNCTION OF THE FIRST and SECOND KINDS, respectively. Note that the CONFLUENT HYPERGEOMETRIC FUNCTION OF THE FIRST KIND is also denoted $M(a,\ c,\ x)$ or $\Phi(a;\ c;\ z)$.

See also CONFLUENT HYPERGEOMETRIC FUNCTION OF

THE FIRST KIND, CONFLUENT HYPERGEOMETRIC FUNCTION OF THE SECOND KIND, GENERAL CONFLUENT HYPERGEOMETRIC DIFFERENTIAL EQUATION, HYPERGEOMETRIC DIFFERENTIAL EQUATION, WHITTAKER DIFFERENTIAL EQUATION

Confluent Hypergeometric Function

CONFLUENT HYPERGEOMETRIC FUNCTION OF THE FIRST KIND, CONFLUENT HYPERGEOMETRIC FUNCTION OF THE SECOND KIND, CONFLUENT HYPERGEOMETRIC LIMIT FUNCTION

Confluent Hypergeometric Function of the First Kind

The confluent hypergeometric function is a degenerate form the HYPERGEOMETRIC FUNCTION ${}_2F_1(a, b; c; z)$ which arises as a solution the CONFLUENT HYPERGEOMETRIC DIFFERENTIAL EQUATION. It is commonly denoted ${}_1F_1(a; b; z)$, $M(a, b, z)$, or $\Phi(a; b; z)$, and is also known as KUMMER'S FUNCTION of the first kind. An alternate form of the solution to the CONFLUENT HYPERGEOMETRIC DIFFERENTIAL EQUATION is known as the WHITTAKER FUNCTION.

The confluent hypergeometric function has a HYPERGEOMETRIC SERIES given by

$${}_1F_1(a; b; z) = 1 + \frac{a}{b} z + \frac{a(a+1)}{b(b+1)} \frac{z^2}{2!} + \ldots$$

$$= \sum_{k=0}^{\infty} \frac{(a)_k}{(b)_k} \frac{z^k}{k!}, \tag{1}$$

where $(a)_k$ and $(b)_k$ are POCHHAMMER SYMBOLS. If a and b are INTEGERS, $a < 0$, and either $b > 0$ or $b < a$, then the series yields a POLYNOMIAL with a finite number of terms. If b is an INTEGER ≤ 0, then ${}_1F_1(a; b; z)$ is undefined. The confluent hypergeometric function is given in terms of the LAGUERRE POLYNOMIAL by

$$L_n^m(x) = \frac{(m+n)!}{m!n!} {}_1F_1(-n; m+1; x), \tag{2}$$

(Arfken 1985, p. 755), and also has an integral representation

$${}_1F_1(a; b; z) = \frac{\Gamma(b)}{\Gamma(b-a)\Gamma(a)} \int_0^1 e^{zt} t^{a-1} (1-t)^{b-a-1}\, dt \tag{3}$$

(Abramowitz and Stegun 1972, p. 505).

BESSEL FUNCTIONS, the ERROR FUNCTION, the incomplete GAMMA FUNCTION, HERMITE POLYNOMIAL, LAGUERRE POLYNOMIAL, as well as other are all special cases of this function (Abramowitz and Stegun 1972, p. 509). Kummer showed that

$$e^x\, {}_1F_1(a; b; -x) = {}_1F_1(b-a, b, x) \tag{4}$$

(Koepf 1998, p. 42).

KUMMER'S SECOND FORMULA gives

$${}_1F_1\left(\tfrac{1}{2} + m; 2m+1; z\right) = M_{0,m}(z)$$

$$= z^{m+1/2}\left[1 + \sum_{p=1}^{\infty} \frac{z^{2p}}{2^{4p} p!(m+1)(m+2)\cdots(m+p)}\right], \tag{5}$$

where ${}_1F_1(a; b; z)$ is the CONFLUENT HYPERGEOMETRIC FUNCTION and $m \neq -1/2, -1, -3/2, \ldots$.

Confluent Hypergeometric Function of the Second Kind

Gives the second linearly independent solution to the CONFLUENT HYPERGEOMETRIC DIFFERENTIAL EQUATION. It is also known as the KUMMER'S FUNCTION of the second kind, the TRICOMI FUNCTION, or the GORDON FUNCTION. It is denoted $U(a, b, z)$ and has an integral representation

$$U(a, b, z) = \frac{1}{\Gamma(a)} \int_0^\infty e^{-zt} t^{a-1} (1+t)^{b-a-1}\, dt$$

(Abramowitz and Stegun 1972, p. 505). The WHITTAKER FUNCTIONS give an alternative form of the solution. For small z, the function behaves as z^{1-b}.

Confluent Hypergeometric Limit Function

$$_0F_1(;\, a;\, z) \equiv \lim_{q\to\infty} {}_1F_1\left(q;\, a;\, \frac{z}{q}\right). \qquad (1)$$

It has a series expansion

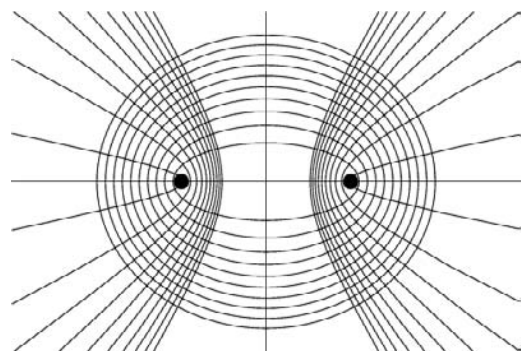
$$_0F_1(; a;\, z) = \sum_{n=0}^\infty \frac{z^n}{(a)_n n!} \qquad (2)$$

and satisfies

$$z\frac{d^2y}{dz^2} + a\frac{dy}{dz} - y = 0. \qquad (3)$$

A BESSEL FUNCTION OF THE FIRST KIND can be expressed in terms of this function by

$$J_n(x) = \frac{\left(\frac{1}{2}x\right)^n}{n!}\, {}_0F_1(;\, n+1;\, -\tfrac{1}{4}x^2) \qquad (4)$$



(Petkovsek *et al.* 1996).

Confocal Conics

Confocal conics are CONIC SECTIONS sharing a common FOCUS. Any two confocal CENTRAL CONICS are orthogonal (Ogilvy 1990, p. 77).

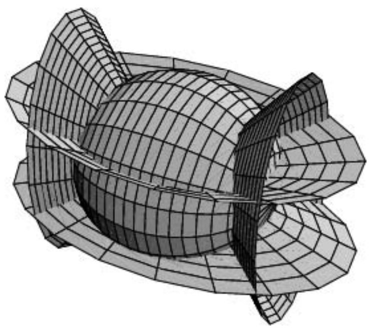
Confocal Ellipses

ELLIPSES sharing common FOCI (left figure). The family of confocal ellipses covers the plane simply, in the sense that there is a unique ellipse passing through each point in the plane (Hilbert and Cohn-Vossen 1999, p. 5). The figure on the right shows confocal ellipses superimposed on CONFOCAL HYPER-



HYPERBOLAS, which form an orthogonal net of curves (Hilbert and Cohn-Vossen 1999, pp. 5–).

Confocal Ellipsoidal Coordinates

The confocal ellipsoidal coordinates, called simply "ellipsoidal coordinates" by Morse and Feshbach (1953) and "elliptic coordinates" by Hilbert and Cohn-Vossen (1999, p. 22), are given by the equations

$$\frac{x^2}{a^2+\xi}+\frac{y^2}{b^2+\xi}+\frac{z^2}{c^2+\xi}=1 \tag{1}$$

$$\frac{x^2}{a^2+\eta}+\frac{y^2}{b^2+\eta}+\frac{z^2}{c^2+\eta}=1 \tag{2}$$

$$\frac{x^2}{a^2+\zeta}+\frac{y^2}{b^2+\zeta}+\frac{z^2}{c^2+\zeta}=1, \tag{3}$$

where $-c<\xi<\infty$, $-b^2<\eta<-c^2$, and $-a^2<\zeta<-b^2$. These coordinates correspond to three CONFOCAL QUADRICS all sharing the same pair of foci. Surfaces of constant ξ are confocal ELLIPSOIDS, surfaces of constant η are one-sheeted HYPERBOLOIDS, and surfaces of constant ζ are two-sheeted HYPERBOLOIDS (Hilbert and Cohn-Vossen 1999, pp. 22–3). For every (x, y, z), there is a unique set of ellipsoidal coordinates. However, (ξ, η, ζ) specifies eight points symmetrically located in OCTANTS.
Solving for x, y, and z gives

$$x^2=\frac{(a^2+\xi)(a^2+\eta)(a^2+\zeta)}{(b^2-a^2)(c^2-a^2)} \tag{4}$$

$$y^2=\frac{(b^2+\xi)(b^2+\eta)(b^2+\zeta)}{(a^2-b^2)(c^2-b^2)} \tag{5}$$

$$z^2=\frac{(c^2+\xi)(c^2+\eta)(c^2+\zeta)}{(a^2-c^2)(b^2-c^2)}. \tag{6}$$

The LAPLACIAN is

$$\nabla^2\Psi=(\eta-\zeta)f(\xi)\frac{\partial}{\partial\xi}\left[f(\xi)\frac{\partial\Psi}{\partial\xi}\right]+(\zeta-\xi)f(\eta)\frac{\partial}{\partial\eta}\times\left[f(\eta)\frac{\partial\Psi}{\partial\eta}\right]+(\xi-\eta)f(\zeta)\frac{\partial}{\partial\zeta}\left[f(\zeta)\frac{\partial\Psi}{\partial\zeta}\right], \tag{7}$$

where

$$f(x)\equiv\sqrt{(x+a^2)(x+b^2)(x+c^2)}. \tag{8}$$

Another definition is

$$\frac{x^2}{a^2-\lambda}+\frac{y^2}{b^2-\lambda}+\frac{z^2}{c^2-\lambda}=1 \tag{9}$$

$$\frac{x^2}{a^2-\mu}+\frac{y^2}{b^2-\mu}+\frac{z^2}{c^2-\mu}=1 \tag{10}$$

$$\frac{x^2}{a^2-\nu}+\frac{y^2}{b^2-\nu}+\frac{z^2}{c^2-\nu}=1, \tag{11}$$

where

$$\lambda<c^2<\mu<b^2<\nu<a^2 \tag{12}$$

(Arfken 1970, pp. 117–18). Byerly (1959, p. 251) uses a slightly different definition in which the Greek variables are replaced by their squares, and $a=0$. Equation (9) represents an ELLIPSOID, (10) represents a one-sheeted HYPERBOLOID, and (11) represents a two-sheeted HYPERBOLOID.

In terms of CARTESIAN COORDINATES,

$$x^2=\frac{(a^2-\lambda)(a^2-\mu)(a^2-\nu)}{(a^2-b^2)(a^2-c^2)} \tag{13}$$

$$y^2=\frac{(b^2-\lambda)(b^2-\mu)(b^2-\nu)}{(b^2-a^2)(b^2-c^2)} \tag{14}$$

$$z^2=\frac{(c^2-\lambda)(c^2-\mu)(c^2-\nu)}{(c^2-a^2)(c^2-b^2)}. \tag{15}$$

The SCALE FACTORS are

$$h_\lambda=\sqrt{\frac{(\mu-\lambda)(\nu-\lambda)}{4(a^2-\lambda)(b^2-\lambda)(c^2-\lambda)}} \tag{16}$$

$$h_\mu=\sqrt{\frac{(\nu-\mu)(\lambda-\mu)}{4(a^2-\mu)(b^2-\mu)(c^2-\mu)}} \tag{17}$$

$$h_\nu=\sqrt{\frac{(\lambda-\nu)(\mu-\nu)}{4(a^2-\nu)(b^2-\nu)(c^2-\nu)}}. \tag{18}$$

The LAPLACIAN is

$$\nabla^2 = 2\,\frac{a^2b^2 + a^2c^2 + b^2c^2 - 2\nu(a^2+b^2+c^2) + 3\nu^2}{(\mu-\nu)(\nu-\lambda)}\frac{\partial}{\partial\nu} + \frac{4(a^2-\nu)(b^2-\nu)(c^2-\nu)}{(\mu-\nu)(\nu-\lambda)}\frac{\partial^2}{\partial\nu^2} + 2\,\frac{a^2b^2 + a^2c^2 + b^2c^2 - 2\mu(a^2+b^2+c^2) + 3\mu^2}{(\nu-\mu)(\mu-\lambda)}\frac{\partial}{\partial\mu} + \frac{4(a^2-\mu)(b^2-\mu)(c^2-\mu)}{(\mu-\lambda)(\nu-\mu)}\frac{\partial^2}{\partial\mu^2} + 2\,\frac{-(a^2b^2 + a^2c^2 + b^2c^2) + 2\lambda(a^2+b^2+c^2) - 3\lambda^2}{(\mu-\lambda)(\nu-\lambda)}\frac{\partial}{\partial\lambda} \qquad (19)$$

Using the NOTATION of Byerly (1959, pp. 252–53), this can be reduced to

$$\nabla^2 = (\mu^2-\nu^2)\frac{\partial^2}{\partial\alpha^2} + (\lambda^2-\nu^2)\frac{\partial^2}{\partial\beta^2} + (\lambda^2-\mu^2)\frac{\partial^2}{\partial\gamma^2}, \qquad (20)$$

where

$$\alpha = c\int_c^\lambda \frac{d\lambda}{\sqrt{(\lambda^2-b^2)(\lambda^2-c^2)}} = F\left(\frac{b}{c}, \frac{\pi}{2}\right) - F\left(\frac{b}{c}, \sin^{-1}\left(\frac{c}{\lambda}\right)\right) \qquad (21)$$

$$\beta = c\int_b^\mu \frac{d\mu}{\sqrt{(c^2-\mu^2)(\mu^2-b^2)}} = F\left[\sqrt{1-\frac{b^2}{c^2}}, \sin^{-1}\left(\sqrt{\frac{1-\frac{b^2}{\mu^2}}{1-\frac{b^2}{c^2}}}\right)\right] \qquad (22)$$

$$\gamma = c\int_0^\nu \frac{d\nu}{\sqrt{(b^2-\nu^2)(c^2-\nu^2)}} = F\left(\frac{b}{c}, \sin^{-1}\left(\frac{\nu}{b}\right)\right). \qquad (23)$$

Here, F is an ELLIPTIC INTEGRAL OF THE FIRST KIND. In terms of α, β, and γ,

$$\lambda = c\ \mathrm{dc}\left(\alpha, \frac{b}{c}\right) \qquad (24)$$

$$\mu = b\ \mathrm{nd}\left(\beta, \sqrt{1-\frac{b^2}{c^2}}\right) \qquad (25)$$

$$\nu = b\ \mathrm{sn}\left(\gamma, \frac{b}{c}\right), \qquad (26)$$

where dc, nd, and sn are JACOBI ELLIPTIC FUNCTIONS. The HELMHOLTZ DIFFERENTIAL EQUATION is separable in confocal ellipsoidal coordinates.

Confocal Quadrics

A set of QUADRATIC SURFACES which share FOCI. Ellipsoids and one- and two-sheeted hyperboloids can be confocal. These three types of surfaces can be combined to form an orthogonal coordinate system known as CONFOCAL ELLIPSOIDAL COORDINATES (Hilbert and Cohn-Vossen 1991, pp. 22–3).

The planes of symmetry of the tangent cone from any point P in space to any surface of the confocal system which does not enclose P are the tangent planes at P to the three surfaces of the system that pass through P. As a limiting case, this result means that every surface of the confocal system when viewed from a point lying on a focal curve and not enclosed by the surface looks like a circle with its center on the line of sight, provided that the line of sight is tangent to the focal curve (Hilbert and Cohn-Vossen 1999, p. 24).

Eliashberg, Y. M. and Thurston, W. P. *Confolations.* Providence, RI: Amer. Math. Soc., 1998.

Conformal Latitude

An AUXILIARY LATITUDE defined by

$$\chi \equiv 2\tan^{-1}\left\{\tan(\tfrac{1}{4}\pi+\tfrac{1}{2}\phi)\left[\frac{1-e\sin\phi}{1+e\sin\phi}\right]^{e/2}\right\}-\tfrac{1}{2}\pi$$

$$=2\tan^{-1}\left\{\frac{1+\sin\phi}{1-\sin\phi}\left(\frac{1-e\sin\phi}{1+e\sin\phi}\right)^{e}\right\}^{1/2}-\tfrac{1}{2}\pi$$

$$=\phi-(\tfrac{1}{2}e^2+\tfrac{5}{24}e^4+\tfrac{3}{32}e^6+\tfrac{281}{5760}e^8+\ldots)\sin(2\phi)$$

$$+(\tfrac{5}{48}e^4+\tfrac{7}{80}e^6+\tfrac{697}{11520}e^8+\ldots)\sin(4\phi)$$

$$-(\tfrac{13}{480}e^6+\tfrac{461}{13440}+\ldots)\sin(6\phi)$$

$$+(\tfrac{1237}{161280}e^8+\ldots)\sin(8\phi)+\ldots$$

The inverse is obtained by iterating the equation

$$\phi=2\tan^{-1}\left[\tan(\tfrac{1}{4}\pi+\tfrac{1}{2}\chi)\left(\frac{1+e\sin\phi}{1-e\sin\phi}\right)^{e/2}\right]-\tfrac{1}{2}\pi$$

using $\phi=\chi$ as the first trial. A series form is

$$\phi=\chi+(\tfrac{1}{2}e^2+\tfrac{5}{24}e^4+\tfrac{1}{12}e^6+\tfrac{13}{360}e^8+\ldots)\sin(2\chi)$$

$$+(\tfrac{7}{48}e^4+\tfrac{29}{240}e^6+\tfrac{811}{11520}e^8+\ldots)\sin(4\chi)$$

$$+(\tfrac{7}{120}e^6+\tfrac{81}{1120}e^8+\ldots)\sin(6\chi)$$

$$+(\tfrac{4279}{161280}e^8+\ldots)\sin(8\chi)+\ldots$$

The conformal latitude was called the ISOMETRIC LATITUDE by Adams (1921), but this term is now used to refer to a different quantity.

Conformal Map

CONFORMAL MAPPING

Conformal Mapping

A conformal mapping, also called a conformal map, conformal transformation, angle-preserving transformation, or biholomorphic map, is a TRANSFORMATION $w=f(z)$ that preserves local ANGLES. An ANALYTIC FUNCTION is conformal at any point where it has a NONZERO DERIVATIVE. Conversely, any conformal mapping of a complex variable which has continuous partial derivatives is analytic. Conformal mapping is extremely important in COMPLEX ANALYSIS, as well as in many areas of physics and engineering.

Several conformal transformations of regular grids are illustrated in the first figure above, and are implemented as `ComplexMap` in the *Mathematica* add-on package `Graphics`ComplexMap`` (which can be loaded with the command `<<Graphics``). In the second figure above, contours of constant $|z|$ are shown together with their corresponding contours after the transformation. Moon and Spencer (1988) and Krantz (1999, pp. 183–94) give tables of conformal mappings.

Let θ and ϕ be the tangents to the curves γ and $f(\gamma)$ at z_0 and w_0 in the COMPLEX PLANE,

$$w-w_0\equiv f(z)-f(z_0)=\frac{f(z)-f(z_0)}{z-z_0}(z-z_0) \qquad (1)$$

$$\arg(w-w_0)=\arg\left[\frac{f(z)-f(z_0)}{z-z_0}\right]+\arg(z-z_0). \qquad (2)$$

Then as $w\to w_0$ and $z\to z_0$,

$$\phi=\arg f'(z_0)+\theta \qquad (3)$$

$$|w|=|f'(z_0)||z|. \qquad (4)$$

A function $f:\mathbb{C}\to\mathbb{C}$ is conformal IFF there are complex numbers $a\neq 0$ and b such that

$$f(z) = az + b \tag{5}$$

for $z \in \mathbb{C}$ (Krantz 1999, p. 80). Furthermore, if $h : \mathbb{C} \to \mathbb{C}$ is an analytic function such that

$$\lim_{|z| \to +\infty} |h(z)| = +\infty, \tag{6}$$

then h is a polynomial in z (Greene and Krantz 1997; Krantz 1999, p. 80).

Conformal transformations can prove extremely useful in solving physical problems. By letting $w \equiv f(z)$, the REAL and IMAGINARY PARTS of $w(z)$ must satisfy the CAUCHY-RIEMANN EQUATIONS and LAPLACE'S EQUATION, so they automatically provide a scalar POTENTIAL and a so-called stream function. If a physical problem can be found for which the solution is valid, we obtain a solution–which may have been very difficult to obtain directly–by working backwards.

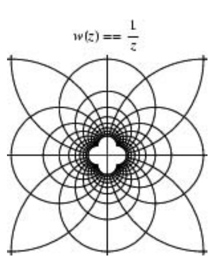
For example, let

$$w(z) = Az^n = Ar^n e^{in\theta}, \tag{7}$$

the REAL and IMAGINARY PARTS then give

$$\phi = Ar^n \cos(n\theta) \tag{8}$$

$$\psi = Ar^n \sin(n\theta). \tag{9}$$

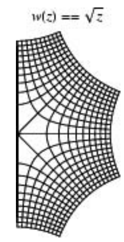


For $n = -2$,

$$\phi = \frac{A}{r^2} \cos(2\theta) \tag{10}$$

$$\psi = -\frac{A}{r^2} \sin(2\theta), \tag{11}$$

which is a double system of LEMNISCATES (Lamb 1945, p. 69).

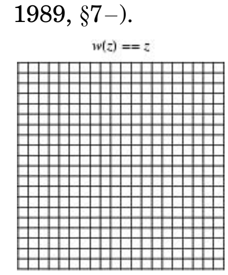


For $n = -1$,

$$\phi = \frac{A}{r} \cos\theta \tag{12}$$

$$\psi = \frac{A}{r} \sin\theta. \tag{13}$$

This solution consists of two systems of CIRCLES, and ϕ is the POTENTIAL FUNCTION for two PARALLEL opposite charged line charges (Feynman *et al.* 1989, §7–; Lamb 1945, p. 69).

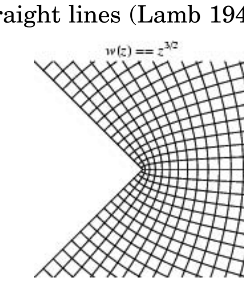


For $n = 1/2$,

$$\phi = Ar^{1/2} \cos\left(\frac{\theta}{2}\right) = A\sqrt{\frac{\sqrt{x^2+y^2}+x}{2}} \tag{14}$$

$$\psi = Ar^{1/2} \sin\left(\frac{\theta}{2}\right) = A\sqrt{\frac{\sqrt{x^2+y^2}-x}{2}}. \tag{15}$$

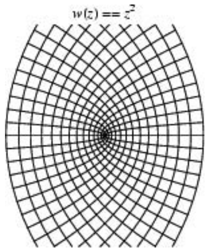
ϕ gives the field near the edge of a thin plate (Feynman *et al.* 1989, §7–).



For $n = 1$,

$$\phi = Ar\cos\theta = Ax \tag{16}$$

$$\psi = Ar\sin\theta = Ay, \tag{17}$$



giving two straight lines (Lamb 1945, p. 68).

For $n = 3/2$,

$$w = Ar^{3/2} e^{3i\theta/2}. \tag{18}$$

ϕ gives the field near the outside of a rectangular corner (Feynman *et al.* 1989, §7–).

For $n = 2$,

$$w = A(x+iy)^2 = A[(x^2-y^2)+2ixy] \quad (19)$$

$$\phi = A(x^2-y^2) = Ar^2 \cos(2\theta) \quad (20)$$

$$\psi = 2Axy = Ar^2 \sin(2\theta). \quad (21)$$

These are two PERPENDICULAR HYPERBOLAS, and ϕ is the POTENTIAL FUNCTION near the middle of two point charges or the field on the opening side of a charged RIGHT ANGLE conductor (Feynman 1989, §7–).

Conformal Projection

A MAP PROJECTION which is a CONFORMAL MAPPING, i.e., one for which local (infinitesimal) angles on a sphere are mapped to the same angles in the projection. On maps of an entire sphere, however, there are usually singular points at which local angles are distorted.

The term conformal was applied to map projections by Gauss in 1825, and eventually supplanted the alternative terms "orthomorphic" (Germain 1865, Lee 1944; Snyder 1987, p. 4) and "autogonal" (Tissot 1881, Lee 1944).

No projection can be both EQUAL-AREA and conform, and projections which are neither EQUAL-AREA nor conformal are sometimes called APHYLACTIC (Lee 1944; Snyder 1987, p. 4).

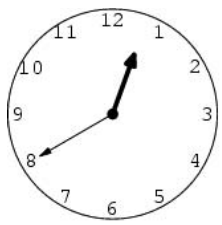
CONFORMAL MAPPING

Congruence

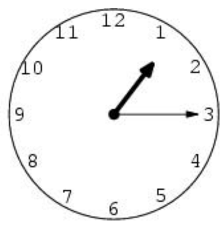
If two numbers b and c have the property that their difference $b-c$ is integrally divisible by a number m (i.e., $b-c/m$ is an integer), then b and c are said to be "congruent modulo m." The number m is called the MODULUS, and the statement "b is congruent to c (modulo m)" is written mathematically as

$$b \equiv c \pmod{m}. \quad (1)$$



If $b-c$ is *not* integrally divisible by m, then we say "b is *not* congruent to c (modulo m)," which is written

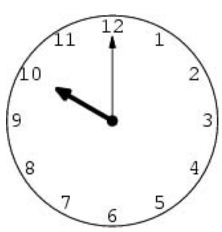
$$b \not\equiv c \pmod{m}. \quad (2)$$



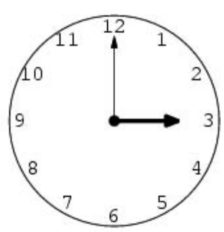
The explicit "(mod m)" is sometimes omitted when the

MODULUS m is understood by context, so in such cases, care must be taken not to confuse the symbol $\equiv$ with the EQUIVALENCE sign.

The quantity b is sometimes called the "base," and the quantity c is called the RESIDUE or REMAINDER. There are several types of residues. The COMMON RESIDUE defined to be NONNEGATIVE and smaller than m, while the MINIMAL RESIDUE is c or $c-m$, whichever is smaller in ABSOLUTE VALUE. In many computer languages (such as FORTRAN or *Mathematica*), the COMMON RESIDUE of $b \pmod m$ is written `mod(b,m)` (FORTRAN) or `Mod[b,m]` (*Mathematica*).



12:40



1:15

Congruence arithmetic is perhaps most familiar as a generalization of the arithmetic of the clock. Since there are 60 minutes in an hour, "minute arithmetic" uses a modulus of $m = 60$. If one starts at 40 minutes past the hour and then waits another 35 minutes, $40 + 35 \equiv 15 \pmod{60}$, so the current time would be 15 minutes past the (next) hour.

10:00

3:00

Similarly, "hour arithmetic" on a 12-hour clock uses a modulus of $m = 12$, so 10 o'clock (a.m.) plus five hours gives $10 + 5 \equiv 3 \pmod{12}$, or 3 o'clock (p.m.)

Congruences satisfy a number of important properties, and are extremely useful in many areas of NUMBER THEORY. Using congruences, simple DIVISIBILITY TESTS to check whether a given number is divisible by another number can sometimes be derived. For example, if the sum of a number's digits is divisible by 3 (9), then the original number is divisible by 3 (9).

Congruences also have their limitations. For example, if $a \equiv b$ and $c \equiv d \pmod n$, then it follows that $a^x \equiv b^x$, but usually not that $x^c \equiv x^d$ or $a^c \equiv b^d$. In addition, by "rolling over," congruences discard absolute information. For example, knowing the number of minutes past the hour is useful, but knowing the hour the minutes are past is often more useful still.

Let $a \equiv a' \pmod m$ and $b \equiv b' \pmod m$, then important properties of congruences include the following, where $\Rightarrow$ means "IMPLIES":

1. Equivalence: $a \equiv b \pmod 0 \Rightarrow a = b$ (which can be regarded as a definition).
2. Determination: either $a \equiv b \pmod m$ or $a \not\equiv b \pmod m$.
3. Reflexivity: $a \equiv a \pmod m$.
4. Symmetry: $a \equiv b \pmod m \Rightarrow b \equiv a \pmod m$.
5. Transitivity: $a \equiv b \pmod m$ and $b \equiv c \pmod m \Rightarrow a \equiv c \pmod m$.
6. $a + b \equiv a' + b' \pmod m$.
7. $a - b \equiv a' - b' \pmod m$.
8. $ab \equiv a'b' \pmod m$.
9. $a \equiv b \pmod m \Rightarrow ka \equiv kb \pmod m$.
10. $a \equiv b \pmod m \Rightarrow a^n \equiv b^n \pmod m$.
11. $a \equiv b \pmod{m_1}$ and $a \equiv b \pmod{m_2} \Rightarrow a \equiv b \pmod{[m_1, m_2]}$, where $[m_1, m_2]$ is the LEAST COMMON MULTIPLE.
12. $ak \equiv bk \pmod m \Rightarrow a \equiv b \left(\bmod \frac{m}{(k, m)}\right)$, where (k, m) is the GREATEST COMMON DIVISOR.
13. If $a \equiv b \pmod m$, then $P(a) \equiv P(b) \pmod m$, for $P(x)$ a POLYNOMIAL.

Properties (6–) can be proved simply by defining

$$a \equiv a' + rd \tag{3}$$

$$b \equiv b' + sd, \tag{4}$$

where r and s are INTEGERS. Then

$$a + b = a' + b' + (r + s)d \tag{5}$$

$$a - b = a' - b' + (r - s)d \tag{6}$$

$$ab = a'b' + (a's + b'r + rsd)d, \tag{7}$$

so the properties are true.

Congruences also apply to FRACTIONS. For example, note that

$$2 \times 4 \equiv 1 \quad 3 \times 3 \equiv 2 \quad 6 \times 6 \equiv 1 \pmod 7, \tag{8}$$

so

$$\tfrac{1}{2} \equiv 4 \quad \tfrac{1}{4} \equiv 2 \quad \tfrac{2}{3} \equiv 3 \quad \tfrac{1}{6} \equiv 6 \pmod 7. \tag{9}$$

To find $p/q \pmod m$, use an ALGORITHM similar to the GREEDY ALGORITHM. Let $q_0 \equiv q$ and find

$$p_0 = \left\lceil \frac{m}{q_0} \right\rceil, \tag{10}$$

where $\lceil x \rceil$ is the CEILING FUNCTION, then compute

$$q_1 \equiv q_0 p_0 \pmod{m}. \tag{11}$$

Iterate until $q_n = 1$, then

$$\frac{p}{q} \equiv p \prod_{i=0}^{n-1} p_i \pmod{m}. \tag{12}$$

This method always works for m PRIME, and sometimes even for m COMPOSITE. However, for a COMPOSITE m, the method can fail by reaching 0 (Conway and Guy 1996). Finding a fractional congruence is equivalent to solving a corresponding LINEAR CONGRUENCE EQUATION

$$ax \equiv b \pmod{m}. \tag{13}$$

Congruence Equation

An equation OF THE FORM

$$f(x) \equiv b \pmod{m}, \tag{1}$$

where the values of $0 \leq x < m$ for which the equation holds are sought. Such an equation may have none, one, or many solutions. There is a general method for solving both the general LINEAR CONGRUENCE EQUATION

$$ax \equiv b \pmod{m} \tag{2}$$

and the general QUADRATIC CONGRUENCE EQUATION

$$a_2 x^2 + a_1 x + a_0 \equiv 0 \pmod{n}. \tag{3}$$

However, solution of the general polynomial congruence

$$a_m x^m + \ldots + a_2 x^2 + a_1 x + a_0 \equiv 0 \pmod{n} \tag{4}$$

is intractable. Note that any polynomial congruence will give congruent results when congruent values are substituted.

Two or more simultaneous congruences

$$x \equiv a \pmod{m} \tag{5}$$

$$x \equiv b \pmod{n} \tag{6}$$

are solvable using the CHINESE REMAINDER THEOREM.

See also CHINESE REMAINDER THEOREM, CONGRUENCE, LINEAR CONGRUENCE EQUATION, QUADRATIC CONGRUENCE EQUATION

Congruence Transformation

A transformation OF THE FORM $g = \mathsf{D}^{\mathrm{T}} \eta \mathsf{D}$, where $\det(\mathsf{D}) \neq 0$ and $\det(\mathsf{D})$ is the DETERMINANT. ISOMETRIES are also called congruence transformations.

See also SYLVESTER'S INERTIA LAW

Congruent

There are at least two meanings on the word congruent in mathematics. Two geometric figures are said to be congruent if they are equivalent to

within ROTATION and TRANSLATION (i.e., IFF one can be transformed into the other by an ISOMETRY). This relationship is written $A \cong B$. Unfortunately, the symbol $\cong$ is also used to denote an ISOMORPHISM.

A number a is said to be congruent to b modulo m if $m|a-b$ (m DIVIDES $a-b$).

Congruent Incircles Point

The point Y for which TRIANGLES BYC, CYA, and AYB have congruent INCIRCLES. It is a special case of an ELKIES POINT.

References

Kimberling, C. "Central Points and Central Lines in the Plane of a Triangle." *Math. Mag.* **67**, 163–87, 1994.

Congruent Isoscelizers Point

In 1989, P. Yff proved there is a unique configuration of ISOSCELIZERS for a given TRIANGLE such that all three have the same length. Furthermore, these ISOSCELIZERS meet in a point called the congruent isoscelizers point, which has TRIANGLE CENTER FUNCTION

$$\alpha = \cos(\tfrac{1}{2}B) + \cos(\tfrac{1}{2}C) - \cos(\tfrac{1}{2}A).$$

See also ISOSCELIZER

Congruum

A number h which satisfies the conditions of the CONGRUUM PROBLEM:

$$x^2 + h = a^2$$

and

$$x^2 - h = b^2,$$

where x, h, a, b are integers. The list of congrua is given by 24, 96, 120, 240, 336, 384, 480, 720, ... (Sloane's A057102).

See also CONCORDANT FORM, CONGRUUM PROBLEM

References

Sloane, N. J. A. Sequences A057102 in "An On-Line Version of the Encyclopedia of Integer Sequences." http://www.re-search.att.com/~njas/sequences/eisonline.html.

Congruum Problem

Find a SQUARE NUMBER x^2 such that, when a given integer h is added or subtracted, new SQUARE NUMBERS are obtained so that

$$x^2 + h = a^2 \quad (1)$$

and

$$x^2 - h = b^2. \quad (2)$$

This problem was posed by the mathematicians Théodore and Jean de Palerma in a mathematical tournament organized by Frederick II in Pisa in 1225. The solution (Ore 1988, pp. 188–91) is

$$x = m^2 + n^2 \quad (3)$$

$$h = 4mn(m^2 - n^2), \quad (4)$$

where m and n are INTEGERS. a and b are then given by

$$a = m^2 + 2mn - n^2 \quad (5)$$

$$b = n^2 + 2mn - m^2 \quad (6)$$

Fibonacci proved that all numbers h (the CONGRUA) are divisible by 24. FERMAT'S RIGHT TRIANGLE THEOREM is equivalent to the result that a congruum cannot be a SQUARE NUMBER.

A table for small m and n is given in Ore (1988, p. 191), and a larger one (for $h \leq 1000$) by Lagrange (1977). The first

$$x = \rho \sin \theta \quad (1)$$

$$y = \rho_0 - \rho \cos \theta, \quad (2)$$

where

$$\rho = (G - \phi) \quad (3)$$

$$\theta = n(\lambda - \lambda_0) \quad (4)$$

$$\rho_0 = (G - \theta_0) \quad (5)$$

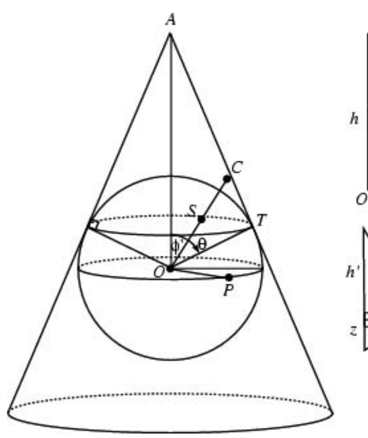
$$G = \frac{\cos \phi_1}{n} + \phi_1 \quad (6)$$

$$n = \frac{\cos \phi_1 - \cos \phi_2}{\phi_2 - \phi_1}. \quad (7)$$

The inverse FORMULAS are given by

$$\phi = G - \rho \quad (8)$$

$$\lambda = \lambda_0 + \frac{\theta}{n}, \quad (9)$$



where

$$\rho = \operatorname{sgn}(n)\sqrt{x^2 + (\rho_0 - y)^2} \qquad (10)$$

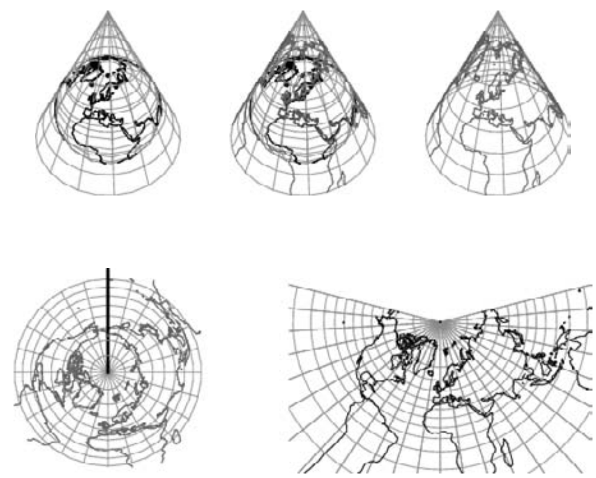
$$\theta = \tan^{-1}\left(\frac{x}{\rho_0 - y}\right). \qquad (11)$$

See also Equidistant Projection

Conic Projection

A conic projection of points on a unit sphere centered at O consists of extending the line OS for each point S until it intersects a cone with apex A which tangent to the sphere along a circle passing through a point T in a point C. For a cone with apex a height h above O, the angle from the z-axis at which the cone is tangent is given by

$$\theta = \sec^{-1} h, \qquad (1)$$



and the radius of the circle of tangency and height above O at which it is located are given by

$$r = \sin\theta = \frac{\sqrt{h^2 - 1}}{h} \qquad (2)$$

$$z = \cos\theta = \frac{1}{h}. \qquad (3)$$

Letting $\phi' = \pi/2 - \phi$ be the colatitude of a point S on a sphere, the length of the vector OC along OS is

$$\begin{aligned} l &= \sec(\theta - \phi') = \sec(\sec^{-1} h - \phi') \\ &= \csc(\phi + \sec^{-1} h). \end{aligned} \qquad (4)$$

The left figure above shows the result of re-projecting onto a plane perpendicular to the z-axis (equivalent to looking at the cone from above the apex), while the figure on the right shows the cone cut along the solid line and flattened out. The equations transforming a point on a sphere (ϕ, λ) to a point on the flattened cone are

$$x = \csc(\sec^{-1} h + \phi)\cos\phi \sin\left(\frac{\lambda}{\sqrt{h^2 - 1}}\right) \qquad (5)$$

$$y = \csc(\sec^{-1} h + \phi)\cos\phi \cos\left(\frac{\lambda}{\sqrt{h^2 - 1}}\right). \qquad (6)$$

This form of the projection, however, is seldom used in practice, and the term "conic projection" is used instead to refer to *any* projection in which lines of latitude are mapped to equally spaced radial lines and lines of latitude (parallels) are mapped to circumferential lines with arbitrary mathematically spaced separations (Snyder 1987, p. 5).

Conic Section

The conic sections are the nondegenerate curves generated by the intersections of a PLANE with one or two NAPPES of a CONE. For a PLANE perpendicular to the axis of the CONE, a circle is produced. For a PLANE which is not perpendicular to the axis and which intersects only a single nappe, the curve produced is either an ELLIPSE or a PARABOLA (Hilbert and Cohn-Vossen 1999, p. 8). The curve produced by a PLANE intersecting both NAPPES is a HYPERBOLA (Hilbert and Cohn-Vossen 1999, pp. 8–).
The ELLIPSE and HYPERBOLA are known as CENTRAL CONICS.

Because of this simple geometric interpretation, the conic sections were studied by the Greeks long before their application to inverse square law orbits was known. Apollonius wrote the classic ancient work on the subject entitled *On Conics.* Kepler was the first to notice that planetary orbits were ELLIPSES, and Newton was then able to derive the shape of orbits mathematically using CALCULUS, under the assumption that gravitational force goes as the inverse square of distance. Depending on the energy of the orbiting body, orbit shapes which are any of the four types of conic sections are possible.

A conic section may more formally be defined as the locus of a point P that moves in the PLANE of a fixed point F called the FOCUS and a fixed line d called the DIRECTRIX (with F not on d) such that the ratio of the distance of P from F to its distance from d is a constant e called the ECCENTRICITY. If $e=0$, the conic is a CIRCLE, if $0<e<1$, the conic is an ELLIPSE, if $e=1$, the conic is a PARABOLA, and if $e>1$, it is a HYPERBOLA.

A conic section with DIRECTRIX at $x=0$, focus at $(p, 0)$, and ECCENTRICITY $e>0$ has Cartesian equation

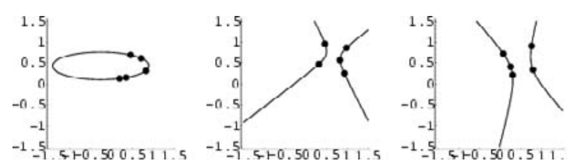
$$y^2+(1-e^2)x^2-2px+p^2=0 \tag{1}$$

(Yates 1952, p. 36), where p is called the FOCAL PARAMETER. Plugging in p for an ELLIPSE gives

$$y^2+(1-e^2)x^2-\frac{2a(1-e^2)}{e}x+\frac{a^2(1-e^2)^2}{e^2}=0, \tag{2}$$

for a PARABOLA (1) simplifies to

$$y^2=4p(x-p), \tag{3}$$



and for a HYPERBOLA, (1) simplifies to

$$y^2+(1-e^2)x^2-\frac{2a(e^2-1)}{e}x+\frac{a^2(e^2-1)^2}{e^2}=0. \tag{4}$$

The polar equation of a conic section with FOCAL PARAMETER p is given by

$$r=\frac{ep}{1+e\cos\theta}. \tag{5}$$

The PEDAL CURVE of a conic section with PEDAL POINT at a FOCUS is either a CIRCLE or a LINE. In particular the ELLIPSE PEDAL CURVE and HYPERBOLA PEDAL CURVE are both CIRCLES, while the PARABOLA PEDAL CURVE is a LINE (Hilbert and Cohn-Vossen 1999, pp. 25–7).

Five points in a plane determine a conic (Coxeter and Greitzer 1967, p. 76; Le Lionnais 1983, p. 56; Wells 1991), as do five tangent lines in a plane (Wells 1991). This follows from the fact that a conic section is a QUADRATIC CURVE, which has general form

$$ax^2+2bxy+cy^2+dx+fy+g=0, \tag{6}$$

so dividing through by a to obtain

$$x^2+2b'xy+c'y^2+d'x+f'y+g'=0 \tag{7}$$

leaves five constants. Five points, (x_i, y_i) for $i=1, ..., 5$, therefore determine the constants uniquely. The GEOMETRIC CONSTRUCTION of a conic section from five points lying on it is called the BRAIKENRIDGE-MACLAURIN CONSTRUCTION.

Two conics that do not coincide or have an entire straight line in common cannot meet at more than four points (Hilbert and Cohn-Vossen 1999, pp. 24 and 160). There is an infinite family of conics touching four lines. However, of the eleven regions into which plane division cuts the plane, only five can contain a conic section which is tangent to all four

lines. Parabolas can occur in one region only (which also contains ellipses and one branch of hyperbolas), and the only closed region contains only ellipses.

Let a polygon of $2n$ sides be inscribed in a given conic, with the sides of the polygon being termed alternately "odd" and "even" according to some definite convention. Then the $n(n-2)$ points where an odd side meet a nonadjacent even side lie on a curve of order $n-2$ (Evelyn *et al.* 1974, p. 30).

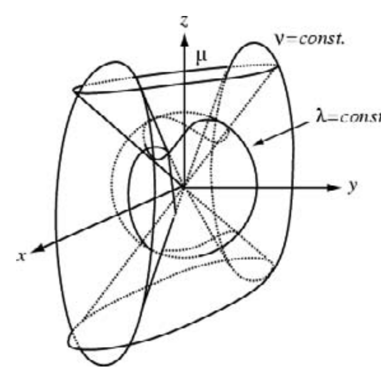
Conic Section Tangent



Given a conic section

$$x^2+y^2+2gx+2fy+c=0,$$

the tangent at $(x_1,\ y_1)$ is given by the equation

$$xx_1+yy_1+g(x+x_1)+f(y+y_1)+c=0.$$

Conical Coordinates

There are several different definitions of conical coordinates defined by Morse and Feshbach (1953), Byerly (1959), Arfken (1970), and Moon and Spencer (1988). The $(\lambda,\ \mu,\ \nu)$ system defined in *Mathematica* is

$$x=\frac{\lambda\mu\nu}{ab} \tag{1}$$

$$y=\frac{\lambda}{a}\sqrt{\frac{(\mu^2-a^2)(\nu^2-a^2)}{a^2-b^2}} \tag{2}$$

$$z=\frac{\lambda}{b}\sqrt{\frac{(\mu^2-b^2)(\nu^2-b^2)}{b^2-a^2}}, \tag{3}$$

where $b^2>\mu^2>c^2>\nu^2$. Byerly (1959) uses a $(r,\ \mu,\ \nu)$ system which is essentially the same coordinate system as above, but replacing λ with r, a with b, and b with c. Moon and Spencer (1988) use (r,θ,λ) instead of $(\lambda,\ \mu,\ \nu)$.

The above equations give

$$x^2+y^2+z^2=\lambda^2 \tag{4}$$

$$\frac{x^2}{\mu^2}+\frac{y^2}{\mu^2-a^2}+\frac{z^2}{\mu^2-b^2}=0 \tag{5}$$

$$\frac{x^2}{\nu^2}+\frac{y^2}{\nu^2-a^2}+\frac{z^2}{\nu^2-b^2}=0. \tag{6}$$

The SCALE FACTORS are

$$h_\lambda=1 \tag{7}$$

$$h_\mu=\sqrt{\frac{\lambda^2(\mu^2-\nu^2)}{(\mu^2-a^2)(b^2-\mu^2)}} \tag{8}$$

$$h_\nu=\sqrt{\frac{\lambda^2(\mu^2-\nu^2)}{(\nu^2-a^2)(\nu^2-b^2)}}. \tag{9}$$

The LAPLACIAN is

$$\begin{aligned}\nabla^2 = & \frac{\nu(2\nu^2-a^2-b^2)}{(\mu-\nu)(\mu+\nu)\lambda^2}\frac{\partial}{\partial\nu} \\ & +\frac{(a-\nu)(a+\nu)(\nu-b)(\nu+b)}{(\nu-\mu)(\nu+\mu)\lambda^2}\frac{\partial^2}{\partial\nu^2} \\ & +\frac{\mu(2\mu^2-a^2-b^2)}{(\mu-\nu)(\mu+\nu)\lambda^2}\frac{\partial}{\partial\mu} \\ & +\frac{(\mu-b)(\mu+b)(\mu-a)(\mu+a)}{(\nu-\mu)(\nu+\mu)\lambda^2}\frac{\partial^2}{\partial\mu^2} \\ & +\frac{2}{\lambda}\frac{\partial}{\partial\lambda}+\frac{\partial^2}{\partial\lambda^2}.\end{aligned} \tag{10}$$

The HELMHOLTZ DIFFERENTIAL EQUATION is separable in conical coordinates.

Conical Frustum

A conical frustum is a FRUSTUM created by slicing the top off a CONE (with the cut made parallel to the base). For a right circular CONE, let s be the slant height and R_1 and R_2 the top and bottom RADII. Then

$$s=\sqrt{(R_1-R_2)^2+h^2}. \tag{1}$$

The SURFACE AREA, not including the top and bottom CIRCLES, is

$$A=\pi(R_1+R_2)s=\pi(R_1+R_2)\sqrt{(R_1-R_2)^2+h^2}. \tag{2}$$

The VOLUME of the frustum is given by

$$V=\pi\int_0^h [r(z)]^2\,dz. \tag{3}$$

But

$$r(z)=R_1+(R_2-R_1)\frac{z}{h}, \tag{4}$$

so

$$\begin{aligned}V &= \pi\int_0^h [r(z)]^2\,dz=\pi\int_0^h\left[R_1+(R_2-R_1)\frac{z}{h}\right]^2 dz \\ &= \tfrac{1}{3}\pi h(R_1^2+R_1R_2+R_2^2).\end{aligned} \tag{5}$$

This formula can be generalized to any PYRAMID by letting A_i be the base AREAS of the top and bottom of the frustum. Then the VOLUME can be written as

$$V=\tfrac{1}{3}h(A_1+A_2+\sqrt{A_1A_2}). \tag{6}$$

The area-weighted integral of z over the frustum is

$$\langle z\rangle=\pi\int_0^h z[r(z)]^2\,dz=\tfrac{1}{12}\pi h^2(R_1^2+2R_1R_2+3R_2^2), \tag{7}$$

so the CENTROID is located along the z-AXIS at a height

$$\bar z=\frac{\langle z\rangle}{V}=\frac{h(R_1^2+2R_1R_2+3R_2^2)}{4(R_1^2+R_1R_2+R_2^2)} \tag{8}$$

(Eshbach 1975, p. 453; Beyer 1987, p. 133; Harris and Stocker 1998, p. 105). The special case of the CONE is given by taking $R_2=0$, yielding $\bar z=h/4$.

Conical Function

Functions which can be expressed in terms of LEGENDRE FUNCTIONS OF THE FIRST and SECOND KINDS. See Abramowitz and Stegun (1972, p. 337).

$$P^{\mu}_{-1/2+ip}(\cos\theta) = 1 + \frac{4p^2+1^2}{2^2}\sin^2(\tfrac{1}{2}\theta) + \frac{(4p^2+1^2)(4p^2+3^2)}{2^2 4^2}\sin^4(\tfrac{1}{2}\theta) + \ldots$$

$$= \frac{2}{\pi}\int_0^{\theta}\frac{\cosh(pt)dt}{\sqrt{2(\cos t - \cos\theta)}}$$

$$Q^{\mu}_{-1/2\mp ip}(\cos\theta) = \pm i\sinh(p\pi)\int_0^{\infty}\frac{\cos(pt)dt}{\sqrt{2(\cosh t + \cos\theta)}} + \int_0^{\infty}\frac{\cosh(pt)dt}{\sqrt{2(\cos t - \cos\theta)}}.$$

Conical Projection

CONIC PROJECTION

Conical Spiral

A SPACE CURVE given by the PARAMETRIC EQUATIONS

$$x = \frac{h-z}{h} r\cos(az)$$

$$y = \frac{h-z}{h} r\sin(az)$$

$$z = z$$

for h the height of the cone, r its radius, and a a constant.

See also CONE, SEASHELL

Conical Surface

GENERALIZED CONE

Conical Wedge

The SURFACE also called the CONOCUNEUS OF WALLIS and given by the parametric equation

$$x = u\cos v$$

$$y = u\sin v$$

$$z = c(1 - 2\cos^2 v).$$
